The *Psychopharmacology Bulletin* is prepared by the Division of Clinical Research of the National Institute of Mental Health. Its purpose is to facilitate the dissemination and exchange of information among the national and international scientific community. This emphasis is on rapid, informal reporting of work which has not appeared in the more formal literature. In accordance with new policy set forth by our Associate Editors, we are no longer accepting unsolicited papers for publication in the *Bulletin*.

All material published in the *Psychopharmacology Bulletin* is in the public domain unless otherwise noted. Publication in the *Bulletin* therefore does not preclude publication elsewhere.

Annual NCDEU Meeting (1985)—Abridged Proceedings

3 **The ECDEU-NCDEU Program**—*Jonathan O. Cole*

Re-Updates: New Perspectives on Long-Standing Issues—

7 Problems With and Promises of Monoamine Oxidase Inhibitors—*Donald F. Klein and Frederic M. Quitkin*

12 New Perspectives on Long-Standing Issues: The Monoamine Oxidase Inhibitors—*Donald S. Robinson*

16 Discussion on the Monoamine Oxidase Inhibitors—*Burtrum C. Schiele*

19 Use of Placebo in Clinical Trials—*Karl Rickels*

25 Scientific and Ethical Considerations in the Use of Placebo Controls in Clinical Trials in Psychopharmacology—*Gerald L. Klerman*

30 The Placebo Control in Clinical Trials (A View From the FDA)—*Paul Leber*

33 Pharmacological Treatments of Schizophrenia—*George M. Simpson*

36 Research Methodology and the Pharmacotherapy of the Chronic Schizophrenias—*Thomas A. Ban, William Guy, and W.H. Wilson*

42 Discussion of Dr. George Simpson's Paper on Pharmacological Treatments of Schizophrenia—*Solomon C. Goldberg*

Multicenter International Clinical Trials—

45 Introduction—*Thomas A. Ban and Jerome Levine*

47 The AMDP System in International Clinical Trials—*B. Woggon, M. Linden, H. Beckmann, E. Krebs, B. Küfferle, B. Müller-Oerlinghausen, B. Pflug, and H.W. Schied*

52 Use of a Standardized Documentation System (BLIPS/BDP) in the Conduct of a Multicenter International Trial Comparing Fluvoxamine, Imipramine, and Placebo—*Giovanni B. Cassano, Luciano Conti, Gabriele Massimetti, Francesco Mengali, Jenifer S. Waekelin, and Jerome Levine*

59 The Design and Conduct of the Upjohn Cross-National Collaborative Panic Study—*Gerald L. Klerman, James H. Coleman, and Robert P. Purpura*

Microcomputers in Clinical Psychopharmacology

65 Why a Statistical Package on a Micro?—*MaryAnn Hill*

73 Microcomputerized Testing of Drug Effects on Divided Attention—*Joe E. Thornton, Joy L. Taylor, Elizabeth L. Gibson, Terry P. Miller, and Jared R. Tinklenberg*

Benzodiazepines—New Indications—

77 The Use of Benzodiazepines for Psychotic Disorders: A Literature Review and Preliminary Clinical Findings—*George W. Arana, Marjorie L. Ornsteen, Fred Kanter, H. L. Friedman, David J. Greenblatt, and Richard I. Shader*

88 New Strategies for the Treatment of Alcohol Withdrawal—*E.M. Sellers and C.A. Naranjo*

93 Benzodiazepines for Treatment of Panic Attacks: A New Look—*Karl Rickels and Edward E. Schweizer*

Cholinergic Mechanisms in the Treatment of Geriatric Disorders—

101 Physostigmine in Patients with Alzheimer's Disease—*Michael Davidson, Richard C. Mohs, Eric Hollander, Bonnie M. Davis, Theresa Ryan, Thomas B. Horvath, and Kenneth L. Davis*

106 Intercranial Drug Administration in Alzheimer's Disease—*Robert E. Harbaugh*

110 The Cholinergic Hypothesis of Memory Dysfunction in Alzheimer's Disease—Revisited—*Nunzio Pomara and Michael Stanley*

Cholecystokinin: A Neuropeptide in the Treatment of Schizophrenia—

119 Ceruletide for Schizophrenia: A Review—*Jeffrey A. Mattes, William Hom, and Joseph M. Rochford*

123 Clinical Evaluation of Ceruletide in Schizophrenia: A Multi-Institutional Cooperative Double-Blind Controlled Study—*Hitoshi Itoh, Yasuo Shimazono, Yukio Kawakita, Yoshio Kudo, Yorio Satoh, and Ryo Takahashi*

129 Cholecystokinin: A Neuropeptide in the Treatment of Schizophrenia—*Carol A. Tamminga, Robert L. Littman, and Larry D. Alphs*

Fenfluramine Therapy for Autism: Promise and Precaution—

133 Fenfluramine Treatment of Autism: UCLA Collaborative Study of 81 Patients at Nine Medical Centers—*Edward R. Ritvo, B. J. Freeman, Arthur Yuwiler, Edward Geller, Phillip Schroth, Alice Yokota, Anne Mason-Brothers, Gerald J. August, William Klykylo, Bennett Leventhal, Kay Lewis, Leonard Piggott, George Realmuto, E. Gene Stubbs, and Richard Umansky*

141 Short-Term Efficacy and Safety of Fenfluramine in Hospitalized Preschool-Age Autistic Children: An Open Study—*Magda Campbell, Stephen I. Deutsch, Richard Perry, Barbara B. Wolsky, and Michael Palij*

148 Fenfluramine: Neurotoxicity—*Charles R. Schuster, Marilyn Lewis, and Lewis S. Seiden*

152 Fenfluramine Treatment of Childhood Attention Deficit Disorder With Hyperactivity: A Preliminary Report—*Maureen Donnelly, Judith L. Rapoport, and Deborah R. Ismond*

155 The Effects of Fenfluramine on Suicidal Behavior—*Elaine Meyendorff, Anil Jain, Lil Traskman-Bendz, Barbara Stanley, and Michael Stanley*

Free Communications—Session A—

161 The Relationship of Antiobsessional and Antidepressant Effects of Tricyclic Antidepressants—*Matig Mavissakalian, Samuel M. Turner, Larry Michelson, and Rolf Jacob*

167 A Comparison of Alprazolam and Imipramine in the Treatment of Agoraphobia and Panic Disorder—*Ross Rizley, Richard J. Kahn, Douglas M. McNair, and Laura M. Frankenthaler*

173 Taper Withdrawal Studies With Alprazolam in Patients With Panic Disorder and Agoraphobia—*John C. Pecknold and Richard P. Swinson*

177 Amitriptyline and Haloperidol in Unstable and Schizotypal Borderline Disorders—*Paul H. Soloff, Anselm George, Swami Nathan, Patricia M. Schulz, Richard F. Ulrich, and James M. Perel*

183 Open Trial of Buspirone in the Treatment of Major Depressive Disorder—*Edward E. Schweizer, Jay Amsterdam, Karl Rickels, Myron Kaplan, and Marian Droba*

186 A Review of Controlled Studies of Adinazolam Mesylate in Patients With Major Depressive Disorder—*John P. Feighner*

192 Chronic Depression: Demographic and Clinical Characteristics—*James H. Kocsis, Carlyle Voss, J. John Mann, and Allen Frances*

196 Self-Rating of Personality Characteristics and Their Relationship to Treatment Response in Recurrent Unipolar Depressives: A Pilot Study—*Ellen Frank, David J. Kupfer, David B. Jarrett, and Miriam Jacob*

200 The Suicide Assessment Scale: A Scale Evaluating Change in Suicidal Behavior—*Barbara Stanley, Lil Träskman-Bendz, and Michael Stanley*

206 A Retrospective Clinical Analysis of the Overall-Rhoades Classification of Hamilton Depression Scale Profiles—*Robert H. Lenox, Lelon A. Weaver, James E. Shipley, and Stephen Cohen*

214 Understanding the Response Lag to Tricyclics: I. Application of Pulse-Loading Regimens With Intravenous Clomipramine—*Bruce G. Pollock, James M. Perel, Michael Shostak, Seymour Antelman, Barbara Brandom, and David J. Kupfer*

220 Pharmacology of Combined Antidepressant/H_2-Blocking Drug Therapy—*Stephen H. Curry, C. Lindsay DeVane, and M. Michael Wolfe*

Free Communications—Session B—

223 Methylphenidate: Rate-Dependent Effects on Hyperactivity—*Mark D. Rapport and George J. DuPaul*

229 The Therapeutic Effect of Clonidine in Attention Deficit Disorder with Hyperactivity: A Comparison With Placebo and Methylphenidate—*Robert D. Hunt, Ruud B. Minderaa, and Donald J. Cohen*

237 The Use of MK-801, a Novel Sympathomimetic, in Adults with Attention Deficit Disorder, Residual Type—*Fred W. Reimherr, David R. Wood, and Paul H. Wender*

243 The Prevalence of Tardive Dyskinesia in a Mentally Retarded Population—*Mary Ann Richardson, Gary Haugland, Raymond Pass, and Thomas J. Craig*

250 Neuroleptic-Induced Tardive Dyskinesia and Parkinsonism: Changes During Several Years of Continuing Treatment—*Daniel E. Casey, Uffe J. Povlsen, Birgit Meidahl, and Jes Gerlach*

254 Integrating Incidence and Prevalence of Tardive Dyskinesia—*John M. Kane, Margaret Woerner, Michael Borenstein, James Wegner, and Jeffrey Lieberman*

259 A Five-Year Follow-Up Study of Tardive Dyskinesia—*Guy Chouinard, Lawrence Annable, Pierre Mercier, and Andree Ross-Chouinard*

264 Plasma Fluphenazine Levels in Patients Receiving Two Doses of Fluphenazine Decanoate—*Stephen R. Marder, John W. Hubbard, Theodore Van Putten, Edward M. Hawes, Gordon McKay, Jim Mintz, Philip R.A. May, and Kamal K. Midha*

267 An Early Phase II Clinical Trial of Remoxipride in Schizophrenia With Measurement of Plasma Neuroleptic Activity—*Guy Chouinard and L. Turnier*

272 Measuring Adverse Drug Reactions in a Postmarketing Surveillance System—*Seymour Fisher, Stephen G. Bryant, and Ronica M. Kluge*

Announcements

Allen Raskin, Ph.D., Editor-in-Chief of the *Psychopharmacology Bulletin* since October 1980, has left the National Institute of Mental Health (NIMH) to become Director of the Psychology Division of Lafayette Clinic and Professor of Psychiatry at Wayne State University in Detroit, Michigan. As indicated in the masthead, he will continue his association with the *Bulletin* as "Special Features Editor."

* * *

The new Editor-in-Chief of the *Bulletin* is Nina R. Schooler, Ph.D., who has been a member of the NIMH staff active in both research and administration in psychopharmacology since 1965. In addition to her position of Editor-in-Chief of the *Bulletin*, Dr. Schooler is also Coordinator for Pharmacologic and Somatic Treatments Research and Assistant Chief of the Schizophrenia Research Branch of NIMH.

* * *

We are pleased to announce that the *Psychopharmacology Bulletin* is now being indexed and abstracted by Excerpta Medica.

* * *

ERRATUM

On page 611 of Vol. 21, No. 3, 1985, the second paragraph under *Methods* reads: "For atenolol, patients first received placebo for a week . . ." There was no placebo week, therefore it should read as follows: "Patients were simply started on atenolol, 50 mg/day. If not improved in 1 week, dosage was raised to 100 mg/day." We regret the error.

Annual NCDEU Meeting (1985)—Abridged Proceedings

The annual meeting of the New Clinical Drug Evaluation Unit (NCDEU) program of the Pharmacologic and Somatic Treatments Research Branch of the National Institute of Mental Health (NIMH) took place on May 1–4, 1985, in Key Biscayne, Florida. The program was developed by the staff of the Branch, Nina R. Schooler, Acting Chief, Jack Blaine, Robert Prien, Allen Raskin, Natalie Reatig, Joanne Severe, and Jerome Levine, former Chief of the Branch.

This was the 25th anniversary meeting of the NCDEU program. The program was established in 1959 by the NIMH as the Early Clinical Drug Evaluation Unit (ECDEU) program with 15 grantees. As described below by Jonathan Cole, the early "invitation-only" meetings for these grant-supported investigators developed into the current format of planned symposia and free communications. Sessions focus on recent research findings in psychopharmacology, methodologic problems and advances in clinical trials in this area, and updates or reviews of significant issues in the field.

The 1985 meeting had 340 attendees including 20 from countries other than the United States.

As in previous years, the Winter issue of the *Bulletin* is devoted to summaries of papers presented at the NCDEU meeting. These summaries are designed to provide early availability of the substance of the meeting to *Bulletin* readers. Publication in the *Bulletin* does not prejudice formal publication of the full papers elsewhere at a later time.

The ECDEU-NCDEU Program

Jonathan O. Cole, M.D.[1]

The New Clinical Drug Evaluation Unit (NCDEU) program had its beginning in the early days of modern clinical psychopharmacology when chlorpromazine was still controversial and psychoanalysis was still more popular and accepted than drug therapy. The National Institute of Mental Health (NIMH) had, perhaps slightly reluctantly, recognized that chlorpromazine and reserpine might be effective unique therapies and used its intramural group, led by Dr. Seymour Kety, to develop a special grant to support an evaluation of the new drugs. A major conference was developed by Dr. Ralph Gerard, then of the University of Illinois Medical School via the National Academy of Sciences (NAS), and I was the NAS staff member who did most of the leg work. The conference was held at the Statler Hotel in Washington, D.C., in September 1956 and eventually published in book form as *Psychopharmacology: Problems in Evaluation*.

About the same time, Dr. Nathan S. Kline and Mike Gorman testified to congressional appropriations committees demanding that the NIMH be given two million dollars a year in grant money to finance a multi-hospital collaborative study of drug efficacy in psychiatry. The NIMH reluctantly accepted the extra money and I was hired to run the new program, I believe because no more senior or distinguished individual was available or interested. The Psychopharmacology Service Center was created and staffed, in its early

---

[1] McLean Hospital, Belmont, MA 02178.

years, by Sherman Ross, Dean Clyde, Lorraine Bouthillet, Seymour Fisher, and Sol Goldberg. Gerald Klerman came on board for 2 years to help mount the original nine-hospital collaborative study of phenothiazines in acute schizophrenia.

In those days the Program had the unique problem of having more money than it could spend. For a number of years the team of Kline and Gorman would urge Congress to appropriate still more money earmarked for research in psychopharmacology, and the NIMH administration would very reluctantly acquiesce and accept the new money. All the NIMH grant programs were rich and, believe it or not, the Mental Health Council would specially review the grants with the *lowest* 10% of the assigned priority scores to decide whether they, too, should be paid!

In this fiscal climate it was possible to propose and actually do large-scale collaborative studies, fund a major data analysis and computer facility to handle the data, and consider open-ended program support for early clinical drug evaluation units (ECDEUs).

The initial ECDEU program was designed to provide stable funding for investigators studying new drugs. Many investigators had programs functioning on fitful drug company grants and some state or Veterans Administration money. The Program was intended to provide core support for key staff and allow some kinds of research not possible on drug company money alone.

The Program was approved and advertised; eventually up to 18 such grants were funded. I believe Leo Hollister and Karl Rickels are the only Principal Investigators whose support has continued uninterrupted since the beginning of the Program. As time went by and research became more sophisticated and money got tighter, it became harder and harder for investigators to get continued support for straight-forward clinical trials of various and often unspecifiable new drugs. As review committees became more restrictive the ECDEU grant program, as originally conceived, gradually died a natural death.

However, the ECDEU meetings developed a life of their own. The meetings originally were designed to bring ECDEU grantees together with NIMH staff once or twice a year to discuss drugs they had been studying, to present data, and to compare impressions. Drug company representatives were originally excluded from the meetings entirely or invited in only when their drug was being discussed. Then there developed a second, open phase of the meeting at which drug company staff were allowed in. Gradually the meetings became totally open. Investigators who had lost grant support continued to attend, and gradually any interested investigator was welcome. The Food and Drug Administration (FDA) sent representatives, and foreign investigators often attended; two original ECDEU grantees were David Wheatley of the United Kingdom and Pierre Deniker of France. I believe the availability of this site in Key Biscayne and Burton Goldstein's willingness to continue as a semi-permanent arrangements committee, and the NIMH staff's availability as a secretariat, and the *Psychopharmacology Bulletin's* availability as a publication outlet, have all kept the meetings interesting, friendly, and productive. Jerry Levine, Nina Schooler, Allen Raskin, and Robert Prien, among others, have done a lot to keep the NCDEU meetings alive and well. They are a unique forum, more open and flexible than the American College of Neuropsychopharmacology, where investigators can exchange communications formally and informally with each other, drug company staff, and FDA staff.

The only comparable series of meetings I know of in medical research are those sponsored now by the Committee on Problems of Drug Dependence (CPDD). They go back well into the 1930's and also are attended by a mix of clinical investigators, basic scientists, drug company investigators and monitors, FDA staff, and foreign workers. Whether my early involvement with this drug abuse and analgesic testing group, then at the NAS, was influential in shaping the present NCDEU program, I cannot tell. If it was, we owe a debt to Dr. Nathan Eddy who essentially ran the CPDD program single handed for many years. He even raised money from drug companies to support free grants made by the NAS, now the CPDD, to investigators to carry out drug screening and clinical trials not committed to any particular company's drug. If federal funds continue to decrease and the drug companies to prosper, the NCDEU program could even end up trying this approach to the funding of some kinds of clinical drug studies.

In any event, I have always enjoyed and learned from NCDEU meetings. If I am partly responsible for the development of this unique and excellent program, I'm very glad. The real credit, obviously, belongs to all the participants over the years. I hope the programs are still as interesting and productive 20 years from now.

Re-Updates: New Perspectives on Long-Standing Issues

CHAIR: Robert F. Prien, Ph.D.
Pharmacologic and Somatic Treatments
Research Branch, NIMH
Rockville, Maryland

Problems With and Promises of Monoamine Oxidase Inhibitors[1]

Donald F. Klein, M.D.,[2] and Frederic M. Quitkin, M.D.[2]

We have been asked to discuss the past history of the use of monoamine oxidase inhibitors (MAOIs), the reason for the recent resurgence in interest, and the range of their demonstrated and possible clinical utility.

What are the characteristics that make for a desirable class of drugs that will incite both clinical investigation and application? A partial list would include the following:

They should be safe, especially from irreversible major side effects, such as stroke or hepatic necrosis.

Their lack of safety should not be made dramatically manifest by their being recalled from the market by the Food and Drug Administration (FDA) for deadly side effects, as occurred with tranylcypromine and iproniazid.

They should lack a wide variety of upsetting, even though reversible, side effects, such as orthostatic hypotension, insomnia, anorgasmia, erectile impairment, weight gain, and hypomania.

They should be easily explained to patients without incurring anxiety over potential catastrophies.

They should require no great modification in the patient's normal life processes. Therefore, they should not require that the patient be on a markedly modified diet.

There should be no threat of dangerous drug interactions.

There should be very clear guidelines as to just what foods or concurrent drugs incur what degree of risk.

There should be no class of drugs, such as the tricyclic antidepressants (TCAs), that are believed to be both safer and more effective for the same class of indications.

Finally, the pharmaceutical industry should believe that an investment in these agents may result in a substantial market penetration with a degree of profit which will make their efforts, in supporting clinical investigation and clinical use, profitable.

From the 1960's through the early 1970's the MAOIs failed by every one of these criteria and were generally considered both ineffective and dangerous. Therefore, they were shunned by both investigators and physicians.

We now know that the early research was flawed, primarily by low dose and inappropriate patient samples. We refer to this as a Phase II deficiency. Unfortunately, many pharmaceutical companies do not realize that controlled trials should be preceded by care-

---

[1] This study was supported in part by USPHS Grants MH-30906 and MH-39143-01 from the National Institute of Mental Health.

[2] New York State Psychiatric Institute, New York, NY 10032.

ful study of dose ranging, latency of onset of therapeutic effect, management of toxicity, and identification of patient types responsive to the drug being studied. Neglect of these essential steps has resulted in the history of psychopharmacology being marred by the frequent release of agents at doses far too low to be generally effective and prescribed for trials of inadequate length (Quitkin et al., 1984). Unfortunately, there are no systematic guidelines to determine the necessary information before proceeding to the design of double-blind, controlled randomized trials. Shortening the time to New Drug Application approval and, therefore, lengthening the time of profitable return is often the motivation for rushing to Phase III. Unfortunately, such a rush often proves shortsighted and poor economy since inadequate Phase III studies are the outcome.

With regard to inappropriate patient samples, the widely quoted Greenblatt et al. study (1964) was generally understood to indicate that isocarboxazid (Marplan) was actually worse than placebo and that phenelzine was equal to placebo. However, this state hospital-based study did not even show imipramine to be effective. Further, in the subgroup of neurotic depressives, phenelzine was 100% effective but, since placebo was 86% effective, the drug could not demonstrate specific benefits in this inappropriate population.

A few English psychiatrists held the fort by claiming specific superiority for the MAOIs over the TCAs for a subgroup of patients they referred to as atypical depressives (Sargant, 1960, 1961; West & Dally, 1959). These patients were primarily described as having non-autonomous mood disorder associated with high levels of anxiety, hyperphagia, and hypersomnia.

In 1969, Klein described a group of patients referred to as hysteroid dysphorics. These patients are characterized by flamboyance, seductiveness, and marked vulnerability to interpersonal rejection, with dramatic crashes in mood associated with leaden paralysis, retreating to bed, and often hypersomnia and hyperphagia (Klein & Davis, 1969). This depression was, however, responsive to positive social input, such as a new boyfriend. The description of this syndrome was important because it focused attention on pathologic rejection sensitivity as a predictor of beneficial effect from MAOI. This work also suggests that some aspects of psychopathology, historically attributed to personality or character disorders, may be a manifestation of an affective disorder, and responsive to antidepressants. Unfortunately, neither the English psychiatrists nor Klein (until recently) conducted any systematic comparative trials contrasting MAOIs and TCAs in the management of such patients.

The entire field was essentially turned around by the work of Robinson, Ravaris, Nies, and co-workers (1973, 1974, 1976, 1978a,b; Ravaris et al., 1976). This team focused clearly and definitively upon the question of dosage adequacy, and identified inhibition of platelet MAO as an objective indicator of dose effectiveness.

In 1973, they published an outpatient trial using 60 mg of phenelzine versus placebo, indicating the drug was effective, safe, and well accepted (Robinson et al., 1973). In 1976 they drove the point home in a comparative study of placebo, 30 mg and 60 mg of phenelzine indicating that 30 mg was no more effective than placebo, whereas 60 mg was substantially superior to both 30 mg and placebo (Ravaris et al., 1976).

These findings made more understandable the negative report of a large study published in 1974 that had used a maximum dose of 45 mg of phenelzine (Raskin et al., 1974). In 1977 there was another positive report by Mountjoy in the English literature of the benefits of 75 mg per day of phenelzine (Mountjoy et al., 1977).

In 1979, Quitkin et al. wrote a detailed critical review of the MAOI literature that summed up the persuasive evidence for their effectiveness in what were usually referred to as neurotic depressives and even the possible benefit of these agents for endogenous depression.

The identification of subtypes of depressives who selectively benefited from MAOIs or TCAs was approached by several investigators, the most prominent being Paykel and Robinson (Robinson et al., 1981; Rowan et al., 1982). Both investigators, in a heterogenous group of outpatients, compared MAOIs, TCAs, and placebo. They found similar overall efficacy for both drugs without very much in the way of predictors of specific efficacy. This was somewhat disheartening but was consistent with the failure of statistical methodology to identify specific drug responsive subgroups from heterogeneous groups of patients.

On moving to Columbia University in 1976, Fred Quitkin, of our group, developed a Depression Evaluation Service and promptly noted that a substantial proportion of our patients fit the criteria for atypical depression. We formalized these criteria emphasizing the essential role of non-autonomous mood disturbance associated with two of four frequently associated symptoms: hyperphagia, hypersomnia, leaden paralysis, and rejection sensitivity. This prospective study comparing phenelzine, imipramine, and placebo has been underway for some years now. It includes the efforts of a large team, in particular Fred Quitkin, Mike Liebowitz, Pat McGrath, Jonathan Stewart, Judy Rabkin, and Wilma Harrison (Liebowitz et al., 1984).

In 1981, Raft and Davidson studied a small sample of depressed patients derived from a pain clinic, and showed the superiority of phenelzine to amitryptyline and the superiority of amitryptyline to placebo (Raft et al., 1981). One conceivable drawback to this study was that it was not clear whether some of the patients might have already proven refractory to tricyclic treatment.

The first report of our effort was published in 1984 on a sample of 60 patients showing, as we had hoped, that phenelzine was indeed superior to imipramine which was superior to placebo (Liebowitz et al., 1984). Sub-analysis of these groups indicated the marked superiority of phenelzine for those considered hysteroid dysphorics and also for those who had a history of panic attacks. The relevance of a history of panic attacks to phenelzine superiority was promptly affirmed by Robinson et al. (1985). We are currently analyzing the data on 120 such patients, and our previous findings hold up well.

One major question is: just what are the boundaries of the atypical depressive syndrome? Our decision to require two out of four associated symptoms was quite arbitrary. As our study progressed, we found patients who only had one or even no associated vegetative atypical symptoms and simply manifested a non-autonomous mood disturbance. We entered these patients, also, along separate tracks, into our randomized trials.

Current analyses of the data revealed similar patterns of medication response. Patients with non-autonomous mood disturbance and any of the four atypical features appear to do better on MAOI, but patients with non-autonomous mood and no atypical features did equally well on a TCA or MAOI (Quitkin et al., 1984). These analyses should be considered preliminary.

Other syndromes also share some resemblance to atypical depression. Tim Walsh, who had been studying bulimics in collaboration with Jonathan Stewart of our Depression Evaluation Service, had developed a double-blind, placebo-controlled trial on phenelzine in bulimics that seemed to indicate that phenelzine is an excellent, at least short-term, treatment for bulimia (Stewart et al., 1984; Walsh et al., 1984).

The marked rejection sensitivity of atypical depressives calls to mind the tremendous fears of humiliation and social scorn present in social phobics and, after promising preliminary studies, Mike Liebowitz is now embarked on a placebo-controlled, double-blind trial contrasting phenelzine, atenolol, and placebo in social phobics.

An important heuristic question is whether the MAOI benefit is limited to patients with non-autonomous mood disorder. Pat McGrath of our Depression Evaluation Service has conducted two small open trials on phenelzine and tranylcypromine in outpatient melancholics. These patients had approximately a 75% response rate (McGrath et al., 1984). In other trials, this patient group had placebo response rates of less than 20%. Clearly, a controlled trial is indicated in this group, also.

There are many questions that remain to be answered. Even such simple issues such as whether tranylcypromine has different effects from phenelzine has not received investigative attention. More complex are the heuristic implications raised by the development of specific inhibitors for MAO A and MAO B (Knoll, 1984). A close reading of the literature indicates that the effect of clorgyline is not clearly established (McGrath & Klein, in press). This is somewhat surprising, considering that this drug has its major effects on just those neurotransmitters that are usually considered central to depressive illness. On the other hand, in a pilot study, deprenyl appears effective in atypical depressives (Quitkin et al., 1984). This drug is now being studied in a controlled trial.

On the horizon is a new class of reversible MAOIs. How they will help our patients and our science is quite unclear to date.

Many of our patients are chronic, dating their illness from adolescence. Can their chronic, dysthymic state be reversed by prolonged MAOI treatment? Do they require chronic maintenance treatment with MAOIs or can their improved state be maintained following drug cessation? Quitkin is pursuing this issue, which has substantial public health importance, in a double-blind discontinuation trial.

To sum up, we seem to be entering a burgeoning period of MAOI research and application. That these useful agents should have been ignored for so long is an unfortunate testimonial to the peculiarities of our profit-oriented drug development system and, in particular, the problems created by Phase II failures of adequate assessment.

New Perspectives on Long-Standing Issues: The Monoamine Oxidase Inhibitors[1]

Donald S. Robinson, M.D.[2]

Monoamine oxidase inhibitors (MAOIs) fell into disuse soon after their introduction into clinical practice 25 years ago. As Dr. Donald Klein points out in the preceding paper, this class of antidepressant drug was supplanted rapidly by the tricyclic antidepressants (TCAs). The MAOIs survived in limited use with a claimed specificity of therapeutic effect for what was termed "atypical depressions" based on experience from uncontrolled studies (Klein, 1969; Sargant & Dally, 1962; West & Dally, 1959). In later controlled trials other investigators (Johnstone & Marsh, 1973; Robinson et al., 1973) confirmed the therapeutic efficacy of phenelzine in the treatment of depression. Recent studies have shown the MAOI phenelzine to be as effective as the TCA amitriptyline in the treatment of depression (Paykel et al., 1980; Ravaris et al., 1980). MAOIs are also at least as effective as existing therapies for phobic and panic disorders (Sheehan et al., 1980). There is little doubt that over the past decade this class of drugs has undergone an impressive resurgence of interest.

Application of modern clinical pharmacologic methods to the study of MAOIs played a role in this recrudescence. Studies based on strict double-blind design, careful baseline evaluation and symptom ratings, with control of critical variables, is essential to clinical psychopharmacology. The importance of these principles was appreciated relatively late in this field and has contributed to conflicting claims about various psychopharmacologic treatments, including the MAOIs.

Burgeoning interest in MAOI research over the past 10 years has resulted in documentation of their effectiveness as general antidepressants. Somewhat unexpectedly, their therapeutic spectrum seems to be broader than the TCAs. Conclusive evidence now exists also for their efficacy in anxiety disorders, including panic disorder and phobic states, and atypical affective disorders such as patients with depression with hysteroid features (Kayser et al., 1985; Liebowitz et al., 1984; Quitkin et al., 1984).

The author's involvement with MAOIs began with development of an assay of *in vivo* MAO inhibition in man which permitted monitoring of the target pharmacologic effect of these drugs in platelets of treated patients (Robinson et al., 1968). This capability proved useful in the clinical pharmacologic study of these drugs, of which relatively little was known, since FDA approval preceded the 1962 amendments to the drug laws. As a consequence, most pre–1962 drugs were lacking in basic knowledge of their pharmacokinetics, therapeutic dose range, or appropriate doses in special populations such as the elderly, and hepatic or renal-impaired patients.

At the time of their approval in 1960, studies in the rat (Gey & Pletcher, 1961) and in man (Ganrot et al., 1962) demonstrated that significant degrees of brain MAO inhibition (75% or greater) were necessary to cause an increase in tissue levels of norepinephrine, serotonin, and dopamine. However, there had been little effort in clinical trials to define adequately the therapeutic dose range, and the prior studies were overlooked. In the early 1970's this led the Vermont group to examine the relationship between platelet MAO inhibition, phenelzine dose, and clinical response of depressed patients (Ravaris et al., 1976). These clinical pharmacologic studies of phenelzine provided a replication of the earlier placebo-controlled efficacy studies (Robinson et al., 1973) and established that the dose of phenelzine is critical in

achieving a therapeutic response. Existing labeling for phenelzine at the time called for inappropriately low doses. The lower end of the therapeutic dose range was found to be 45 mg/day. The data suggested also that the dose-response curve might not be linear. It appeared that a threshold inhibition level of at least 80% (using benzylamine as substrate) was associated with onset of therapeutic effect in depression (Ravaris et al., 1976; Robinson et al., 1978). Subsequently, dosage recommendations have been modified to be 60 to 90 mg/day for most patients.

An important question remaining to be answered is the optimal duration of treatment with an MAOI to maintain a patient in remission following treatment of an index episode. Studies are now in progress at two centers to address this critical issue. Interim results of these ongoing studies are not yet available, but there is early evidence that phenelzine treatment should be continued beyond 6 months for most patients. Selected patients with chronic or recurrent depression may require MAOI treatment for several years.

Studies have shown the optimum daily therapeutic dose of phenelzine to be approximately 1 mg/kg/body weight (Robinson et al., 1978a,b). Recent experience (Lerfald and Robinson, unpublished data) indicates that patients can be started initially at full therapeutic dosage. One would predict it should be possible to use a "loading dose" during the first week of treatment without increased risk of side effects which might accelerate the therapeutic response.

The strategy of employing a multiple fixed-dose design in Phase II studies of antidepressants is an important concept. The advantages of such designs are generation of vital dose-ranging data required for Phase III trials and clinical practice. Such dose-ranging studies, if properly designed, can also provide important efficacy data. Because of the time-consuming and expensive nature of Phase III studies, it is important to define an effective, safe dose as early as possible in the development of antidepressant drugs. Definitive, well-designed studies are key since outcome measures lack precision in psychopharmacology in comparison to many other fields of investigation, and perhaps even more critical is the temporal dissociation between initiating drug treatment, or making a dose adjustment, and the resulting therapeutic effect.

Finally, there is emerging evidence that MAOIs have specific anxiolytic effects in addition to intrinsic antidepressant activity. This possibility is supported by studies in phobic disorders (Solyom et al., 1973; Tyrer et al., 1973), depression with prominent somatic anxiety (Nies et al., 1982), depression with panic symptoms (Liebowitz et al., 1984; Robinson et al., 1985), and panic disorder (Sheehan et al., 1980). Studies by our group have shown phenelzine to have equivalent antidepressant efficacy to amitriptyline in major depression with enhanced antianxiety properties in these patients compared to the TCAs (Robinson et al., 1985). Phenelzine relieves both psychic and somatic symptoms of anxiety associated with depression.

The recent interest in serotonin as a primary neurotransmitter mediating mood and anxiety states (Peroutka & Snyder, 1980; Taylor et al., 1981) has important implications for the MAOIs. This class of drug is known to profoundly affect brain serotonin levels and to inhibit serotonergic neurotransmission (Blier & deMontigny, in press). There is increasing evidence that serotonergic systems may play a central role in modulating anxiety and tension states in conjunction with the noradrenergic systems which mediate outflow from the locus ceruleus. Anxiolytic agents, including the benzodiazepines and buspirone, share a common property of profoundly inhibiting serotonergic neurotransmission in the dorsal raphae nucleus. It is postulated that anxiety agents achieve their clinical effects by inhibiting raphae input to the septo-hippocampal system. However, buspirone, unlike the benzodiazepines, does not inhibit spontaneous firing of cells in the locus coeruleus (Sanghera et al., 1983) and actually mildly enhances noradrenergic firing. This would suggest that a decrease in serotonergic activity mediates a therapeutic anxiolytic drug effect.

An analogous situation may apply to the MAOIs which can markedly increase brain serotonin (Robinson et al., 1979) and inhibit dorsal raphae firing, in addition to their better known effects on noradrenergic systems. Current electrophysiologic and neurochemical studies may provide a basis for understanding the mechanism of action of MAOIs which probably involves a profound effect on serotonergic systems.

Summary

MAOIs are attracting intense interest, both scientifically and clinically, because of a broad spectrum of therapeutic actions. Studies support significant efficacy in the treatment of depression and anxiety disorders. Evidence from recent controlled trials, as well as clinical experience, shows MAOIs to be effective in both endogenous and nonendogenous types of major depressive disorder, atypical depression, depression with hysteroid features, and depression associated with panic attacks. In addition, MAOIs are considered to be one of the most effective treatments for panic disorder. Preliminary evidence suggests some benefit for eating disorders, social phobias, and obsessive compulsive disorder.

Relatively little is known about the need for long-term therapy with antidepressant drugs, including the MAOIs. Until the findings of ongoing studies become available, maintenance MAOI treatment should continue for a minimum of 6 months and probably longer in selected patients with chronic or recurrent depression.

At optimal dosage of phenelzine (1 mg/kg per day) an overall treatment response rate of 85 to 90% can be anticipated in major depression irrespective of subtype. Clinical pharmacology studies of antidepressant drugs can contribute to their rational use in a wide spectrum of mood and anxiety disorders.

Discussion on the Monoamine Oxidase Inhibitors

Burtrum C. Schiele, M.D.[1]

Jonathan Cole gave the keynote address in which he described how Congress was impressed in the 1950's with the great potential of chlorpromazine and other antipsychotic drugs for reducing the morbidity of mental illness. As a result, Congress gave Dr. Cole's Psychopharmacology Service Center 2 million dollars in 1956 to stimulate research. There was a paucity of good research at that time and Jon Cole and his colleagues had to "beat the bushes" for suitable grantees. This probably explains why he told me in 1959 to apply for research money, stating that "you fellows in Minnesota are doing some pretty good work." We received 1.4 million dollars in direct costs over a 12-year period and the University received as overhead about 400,000 dollars. This support resulted in over 150 clinical trials on investigational compounds. The results from most of these trials were published.

More importantly, our Early Clinical Drug Evaluation Unit (ECDEU) operation stimulated similar efforts at other centers such as the St. Paul-Ramsey Medical Center, the Missouri Institute of Psychiatry, and the Veterans Administration Medical Center in St. Cloud, Minnesota. Approximately 50 colleagues participated in these clinical trials. For many, this was a first research effort resulting in publication. Over the years, these colleagues published several hundred additional articles in psychopharmacology. Even those who did not pursue research received lasting benefits through a greater appreciation of what psychotropic drugs can and cannot do, and through familiarity with the scientific measurement of behavioral change developed by psychopharmacologists.

"New Perspectives on Long-Standing Issues" was the title of the first scientific session. Dr. Donald Kline gave a scholarly dissertation on the ups and downs of the monoamine oxidase inhibitors (MAOIs). This class of drugs historically provided the first effective modern antidepressants. The original drug, iproniazid (Marsalid), initially generated great excitement, as it appeared to have potent antidepressant action. Unfortunately, it also produced jaundice and liver damage and was removed from the American market, though it is still commercially available in Canada and the United Kingdom. A number of MAOIs were marketed but only three remain on the American scene: isocarboxazid (Marplan) and phenelzine (Nardil) are hydrazine MAOIs and tranylcypromine (Parnate) is a nonhydrazine MAOI.

The early studies evaluating the effectiveness of the MAOIs were slip-shod and poorly designed by today's standards. Nevertheless, the drugs were widely used until tricyclic antidepressants (TCAs) became available. At this time, the so-called "cheese" reaction, or hypertensive headache crisis, began to appear in patients who were taking the MAOIs. In a short time, these drugs were in disrepute and were rarely used. However, in the late 1970's there was a considerable resurgence of interest in them. This is due to the fact that better designed studies were being conducted. One of the best was a study by Dr. Donald Robinson on Nardil. He demonstrated that the effective dose level was considerably greater than what had originally been recommended, and that patients must be carefully selected. In carefully controlled trials, Nardil proved to be equal in efficacy to the TCAs. Also, a biologic measure of MAO action was available by measuring the platelet MAO content.

A second factor that created further interest in these agents was the advent of several new types of MAOIs based upon the discovery of agents that were highly selective for the two major classes of MAO, Types A and B. A selective MAOI, chlorgyline, acted on

---

[1] Emeritus Professor of Psychiatry, University of Minnesota, Minneapolis, MN 55455.

MAO-A but showed no safety advantage over the already existing MAOIs and is no longer manufactured. One of the more promising drugs is L-deprenyl, which is selective for MAO-B. MAO-A denatures norepinephrine, 5–HT, and dopamine, while MAO-B denatures dopamine and phenethylamine. L-Deprenyl apparently does not alter tyramine and, thus, is considerably less dangerous than the traditional MAOIs. It is marketed in England and other European countries as an antiparkinson drug where it is causing few difficulties and is associated with little orthostatic hypotension.

My main role in this presentation is to discuss Parnate (tranylcypromine). This agent is unlike the other MAOIs in that it has a bimodal stimulating action that occurs very quickly, whereas the hydrazine MAOIs may require several days or weeks before the antidepressant effect is apparent. Parnate has not been associated with liver troubles, tremor, or sweating as have the hydrazine drugs. In the early days, it appeared to be a drug of choice, partly because of its rapid onset of action and high potency. Before long, however, the drug began to show a higher incidence of hypertensive crisis than did the other drugs and so fell into disrepute. This was particularly true in England, where many people eat a whole meal of cheese; patients who were on Parnate often had hypertensive crises after eating ripe cheese or other tyramine-laden foods. A number suffered strokes, and there were some deaths. As a result, in 1964 the FDA threatened to seize the drug and the manufacturer removed it voluntarily from the market. Because of the large number of letters of protest, mostly from physicians who claimed to have patients who were benefiting greatly from Parnate and who had benefited from nothing else, the FDA reversed its decision and the drug was returned to the marketplace within a few months. However, severe restrictions were placed upon its use. The dose was lowered, it was not to be given to people over 60 years of age, and there was a long list of prohibited foods and drugs which should not be used while the patient was taking Parnate.

When the Drug Evaluation Scientific Inventory (DESI) studies were completed, Parnate was given a rating of less than efficacious. The rating has not been changed in spite of the fact that the manufacturer claims to have completed two well-designed studies in the last year that show its efficacy. I understand that new labeling is being developed and that the dose will be raised and restrictions lessened.

Most patients do not respond to Parnate, but it is easy to determine in a few days whether or not they will respond. Of those who do, many demonstrate dramatic improvement. To illustrate, a 43-year-old university graduate had been incapacitated by anxiety and depression for over 20 years. He had failed to respond to psychotherapy, ECT, and many new drugs and had spent the last 10 years in Anoka State Hospital. He had the good fortune to be placed on Parnate while a subject in one of our first double-blind trials under the ECDEU program. Within 3 days he was vastly improved. That Parnate was largely responsible for this improvement is supported by the fact that his fears and anxiety began to return when Parnate was taken off the market. He improved when Parnate supplies were made available to him, and went on to a complete and lasting recovery.

The aforementioned patient is a classical MAOI responder. Some responders, however, may be schizophrenic. One such patient had had florid schizophrenia for many years and had failed to obtain lasting benefit from extensive ECT, many drugs, and years of hospitalization. Surprisingly, she obtained lasting benefits from Parnate. A trial of Parnate (or other MAOI) in treatment-resistant schizophrenics who are tense and anxious or fearful may be worthwhile. A problem is that some schizophrenics may develop more florid symptomatology on Parnate, in which event the MAOI should be discontinued.

The official label says Parnate should be used only in "severe depressions." This wording needs to be improved because most of those who benefit have atypical depression, if they are depressed at all. They often have chronic fears and anxiety, and a few have frank schizophrenia or schizophrenic tendencies.

Parnate is sufficiently different from the hydrazine MAOIs and should not be lumped with these. Studies are needed to compare Parnate against the hydrazine MAOIs. If

Parnate responders would do as well on the hydrazine MAOIs, the latter may be preferred because of a somewhat better safety record.

One of my last ECDEU projects (about the time of my retirement) was an interesting study of Parnate's isomers. Commercial Parnate is a racemic mixture of plus and minus isomers. Dr. Solomon Snyder told us that animal studies suggested that the minus isomer might have greater therapeutic value and less toxicity. Our short-term trial on 11 depressed subjects indicated that he was correct. Unfortunately, as far as I know, no further studies on this intriguing matter have been carried out.

Use of Placebo in Clinical Trials[1]

Karl Rickels, M.D.[2]

It is now almost 40 years since the "Cornell Conference on Therapy" was held (Cornell Conference on Therapy, 1946). It was a "first" in medicine with its primary focus on placebo effects and double-blind methodology. In the late 1940's and early to late 1950's, Beecher and his associates conducted leading research on the patients' subjective response to active drug treatment, primarily analgesics, and to placebo (Beecher, 1955, 1959).

But it was the discovery of chlorpromazine and reserpine, two antipsychotic drugs, in the early 1950's that began to revolutionize clinical research methodology. The discipline of "psychopharmacology" was born.

Psychiatry, a medical specialty that in the early 1950's had almost rejected its medical roots and had embraced a concept of psychological and behavioral causation for most psychiatric illnesses, suddenly found itself with pharmacological tools to modify behavior significantly and to produce frequently lasting improvement. Soon, other neuroleptic agents, as well as drugs to treat anxiety and insomnia, such as meprobamate and the benzodiazepines, drugs to treat depression such as monoamine oxidase inhibitors (MAOIs) and tricyclics, and lithium to treat mania, were also introduced into medicine. The young leaders of this new field of psychopharmacology took the opportunity which was offered to them and forged ahead to develop the discipline of psychopharmacology and make it a leader in clinical research and clinical pharmacology.

The Psychopharmacology Service Center (NIMH-PSC) was created in 1956, changing its name in the early 1960's to the Psychopharmacology Research Branch (NIMH-PRB). NIMH research support multiplied and the judicious support of well-controlled, frequently placebo-controlled clinical trials, conducted both at individual research centers and as collaborative enterprises, carried out with schizophrenic, depressed, manic-depressed, and anxious patients, led to important clinical findings and to advances in research methodology not found, at least at that time, in other medical specialties. Another important driving force behind the excellent clinical collaborative research conducted in the early years of psychopharmacology was the central office of the Veterans Administration.

In these early years of psychopharmacology, industry lagged in its support of clinical research. In fact, most well-controlled studies in the 1960's were government supported. Industry had no real incentive as drugs could get approved rather easily, having to demonstrate only safety but not efficacy.

It is for this reason, but also for the fact that most schizophrenic patients lived in state hospitals and were not treated by private or academic psychiatrists, that much of the early clinical research with neuroleptics and antidepressants was conducted in relatively few State hospitals by such early leaders of psychopharmacology as Fritz Freyhan, Nathan Kline, Milton Greenblatt, Heinz Lehmann, and others.

In 1960, the first NIMH-sponsored collaborative study involving the treatment of anxious outpatients was conducted jointly by NIMH, Johns Hopkins, and the University of Pennsylvania (Fisher et al., 1964; Uhlenhuth et al., 1966), soon to be followed by in- and outpatient studies in depression.

All of these early NIMH and VA-sponsored studies employed already sophisticated research methodology, including the use of placebo and standard controls, randomization, placebo washout, and double-blind design.

[2] Stuart and Emily B.H. Mudd Professor of Human Behavior and Professor of Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

Since in psychiatry probably more than in any other field of medicine, nondrug or nonspecific factors, including the treatment milieu (Rickels, 1968), exert an important impact on treatment outcome, the use of controls, frequently placebo, became a methodological necessity. The more patients were studied, the more the phenomenon to be studied changed, the well-known Heisenberg phenomenon.

Thus interest in the placebo response in psychiatry intensified during the late 1950's and 1960's and led to a burst of publications including many by the author and his colleagues (Downing & Rickels, 1970; Downing et al., 1981; Honigfeld, 1964). Placebo controls were and are still being used primarily for two reasons: to control for effects due to suggestibility, including milieu or psychotherapy, bias, and enthusiasm of both patient and physician; and also to control for spontaneous symptom change or remission occurring while in treatment but being unrelated to the specific treatment offered.

While the use of placebo is probably more important in evaluating new treatments for anxiety, panic disorder, depression, Alzheimer's disorder, and insomnia, it also plays an important role in drug trials conducted with chronic and acute schizophrenic patients.

The appropriate use of placebo controls in psychopharmacology has been clearly defined in the Food and Drug Administration (FDA) guidelines for clinical trials of psychotropic drugs. These guidelines were drafted by a committee consisting of members of the American College of Neuropsychopharmacology (ACNP) and Early Clinical Drug Evaluation Unit (ECDEU), coming from government, academia, and industry (FDA Guidelines for Psychotropic Drugs, 1974; International Guidelines for Clinical Trials of Psychotropic Drugs, 1978; FDA Guidelines for the Clinical Evaluation of Psychotropic Drugs—Antidepressants and Antianxiety Drugs, 1978; Wittenborn, 1977). In fact, the discipline of psychopharmacology was instrumental in the development of FDA guidelines, not only for psychiatry, but also for other fields in medicine. One of the most important publications relevant to the topic at hand which resulted from close collaboration between members from NIMH and ACNP, many of them also members of ECDEU, should be mentioned here. It is edited by Jerome Levine and was entitled "Principles and Problems in Establishing the Efficacy of Psychotropic Agents" (Levine et al., 1971).

Today it is difficult sometimes to separate activities sponsored by PRB, ECDEU, or ACNP. Yet the PRB and the ECDEU are probably most closely intertwined. It is now 25 years since the ECDEU, later changed to NCDEU, was launched to bring together clinical researchers, scientists, and administrators from academia, government, and industry with the explicit goal to improve communications between those involved in psychiatric clinical research.

Another important factor contributing to improved drug evaluation methodology has been the Kefauver-Harris Amendment to the Food, Drugs, and Cosmetic Act of 1962 (Kefauver-Harris Amendments of October 10, 1962, to the Food, Drugs, and Cosmetic Act, 1962). It mandated that the FDA evaluate not only safety but also efficacy claims for any new experimental agent before approving it for general use.

As a member of the drug efficacy study (National Academy of Sciences/National Research Council, 1969) evaluating psychiatric drugs, a study which was conducted between 1966 and 1968, sponsored by the National Academy of Sciences, and which reviewed for the FDA all drugs introduced between 1938 and 1962, I became clearly aware of industry's frequent lack of interest in controlled research methodology, at times not without reason, as drugs were possibly only of marginal effectiveness. The absence of well-controlled clinical trials could again not be missed (Department of Health, Education, and Welfare, 1978) when I was chairman of the FDA Psychiatric OTC Review Panel in the 1970's.

Since clinical drug trials and the use of experimental drugs and placebo are intimately interwoven with ethical questions involving the protection of human subjects, the USPHS and the FDA independently moved ahead over the years with a number of regulations to assure subject rights and good research methodology. For example, in 1966 the USPHS published its first proposal to establish Institutional Review Boards (U.S. Public Health Service, 1966) and in 1970 the FDA published its first final rules for "Adequate and Well-Controlled Clinical Evaluations" (*Federal Register*, 1970).

Improvement of research methodology and the use of placebo parallels the increasing ethical and methodological concerns regarding the use of placebo in double-blind studies (Helmchen & Müller-Oerlinghausen, 1978).

The conduct of clinical research and the protection of human subjects has been guided since World War II by the Nuremberg Code (Office of the Adjutant General of the United States, 1947), the Declarations of Helsinki (World Medical Assembly, 1964) and Tokyo (World Health Assembly, 1975), and the Declaration of Hawaii (World Psychiatric Association, 1977). This is not to say that ethical concerns regarding clinical research and the use of placebo have not been around for some time. Sir Thomas Percival, for example, discussed placebo use in his 1803 published treatise on "Medical Ethics," and Hooper's "Medical Dictionary," published in 1811, described placebo as "an epithet given any medicine adopted more to please than to benefit the patient." Placebo controls were advocated by Dr. James Lind as early as 1753 when he evaluated the effects of lime juice on scurvy.

More recently, Beecher has given a striking example of placebo effects in surgery (1968). In the 1940's it was an in-vogue procedure to perform a ligation of the internal mammary arteries for the treatment of angina pectoris. Starting in Italy, this surgical procedure entered the United States with great enthusiasm, but when finally a controlled study was evaluated in which half the patients received ligation and the other half simply a skin incision, both groups of patients showed similar levels of improvement.

Over the years, many criticisms of the use of placebo have been voiced (Burkhardt & Kienle, 1978; Freiman et al., 1978; Editorial, 1979). Let us first discuss those voiced on methodological grounds, as placebo is frequently attacked by the statement that "everyone can break the design." To such criticism, Lasagna answered most succinctly many years ago (1971):

1. It is rare for a drug to produce side effects in all patients.
2. It is rare for a placebo not to produce side effects in some patients.
3. The production of side effects is not clearly correlated with desired therapeutic effects.
4. Analyses can always be performed to investigate the possible correlation of side effects and therapeutic success.
5. Coding can and should be done individually so that one code break does not bias all of the subsequent observations.
6. Even an obvious detectable placebo may still serve as a control for spontaneous improvement, unrelated to suggestibility which is at times the main or sole component of the placebo response.
7. Even a partial control on subject and observer bias is infinitely better than no control at all.

There do exist, however, a couple of problems when including placebo control groups. First, patients assigned to placebo studies may tend to be less ill than patients assigned to studies not including a placebo group and thus are not representative of all patients and, secondly, study enrollment will be more difficult.

What are some of the major ethical concerns?

1. Placebo use is a deception.
2. Placebo use withholds otherwise available effective therapy.
3. Placebo use actually endangers the life and welfare of the patient.

Some suggest that one can deal with some of these issues by using a small "ineffective" dose of an active drug as a control. I am against such an approach since I consider it indeed a deception of the patient.

Opponents of placebo use seem to suffer from the delusion that placebos are always ineffective and experimental drugs are always safe and effective. I personally subscribe to the statement made by Lasagna some time ago that "too often the placebo-treated patients turn out to be the lucky ones in a drug trial, deprived only of a toxic and ineffective chemical" (Lasagna, 1970). In fact, it is indeed surprising to me how frequently any, at least potentially, poisonous experimental compound will be readily prescribed to patients without great ethical concerns while a safe placebo will be considered unethical.

This lack of placebo control renders the results of many clinical drug trials meaningless, useful only for drug promotion. I subscribe to Robert Temple's view (Temple, 1984) that an "escape clause" or "easy escape" can be developed for almost any placebo application in situations where it appears to be difficult to use placebo controls for ethical and/or clinical reasons. Many examples could be quoted for such consideration. Suffice it to say that placebo has been meaningfully used in all psychiatric conditions, including schizophrenia and mania.

In some conditions, for example, instead of starting with a parallel group design, one might treat patients only with an experimental or standard agent, and then shift those responding to treatment to either placebo or continued medication. An escape clause should allow a subject to resume active drug therapy only after minimal signs of relapse occur. Such designs have certainly been successfully used in mania, schizophrenia, and depression, to mention only some psychiatric indications.

What are other control options if a placebo is not used? One is the use of "historical controls," an option which in my opinion is not very helpful in most instances. Another option is the use of dose response curves but, in my opinion, even here a placebo group is needed. Finally, the use of standard agents without a placebo control group is recommended. However, unless studies comparing an experimental with a standard agent are of large sample size, involving 100 to 200 patients per treatment cell, only positive but not negative findings are interpretable (Gillings et al., 1984). A failure to include a placebo in such trials may lead to difficulty in interpreting the results. For example, the test drug may turn out to be inferior to the standard drug. Without a placebo, however, it will be impossible to say whether the test drug has any activity at all, a question probably of interest, particularly if the experimental agent has many fewer side effects than the standard agent. In another experiment, the test drug and standard drug may perform equally well. Without a placebo control, however, one does not know whether both drugs are equally effective or ineffective, or whether one was merely dealing with an experimental sample or design unable to discriminate between treatments. Therefore, it is my considered opinion that three treatment groups, namely experimental agent, placebo, and standard agent, are necessary for most appropriate study results interpretation. Here we can compare the experimental drug against the yardstick of standard drug versus placebo response.

Once clinical efficacy has been clearly established, however, I am the last person to demand a placebo group in all additional studies. Yet I know even here of many instances in which the sponsors wished they had included a placebo group. Nevertheless, research questions such as those related to differential drug effects or safety, to the relationship of drug response and drug plasma levels, and many others can be answered without using a placebo control group.

Before concluding, allow me to cite two recent experiences pointing out the importance of placebo controls. In an ongoing trial involving alprazolam, imipramine, and placebo in agoraphobic panic patients, a patient entered the trial who, after gradual increase of dosage during the first 4 weeks, responded with full remission of symptoms, symptoms she had had for many years and which had not responded to psychotherapy and other therapeutic modalities. In fact, the patient was so much improved that she appeared together with me on a radio show and before a class of 165 medical students where she completely upstaged me. Her symptoms clearly responded to treatment and the drug in question appeared to be (to everyone concerned) alprazolam, as the patient described temporary memory problems and sedation with increased dosages but no autonomic nervous system side effects. After 8 weeks, her daily dosage was slowly decreased and when she reached half the daily dosage her symptoms returned. Once a full daily dosage was again established, the patient was symptom-free for about 4 months, at which time she began slowly to relapse, needing increasing amounts of "medication," until finally she demanded to be taken off the study and to know what she was receiving. To our great surprise, when the code was broken, the patient was found to have been on placebo. Thus for more than 4 months the patient responded significantly and better than she had ever before to the supportive milieu of a special panic disorder clinic, an effect not at all drug related.

The second example is a patient suffering from major depressive disorder of the melancholic subtype who participated in a study comparing the use of imipramine, alprazolam, and placebo in depression. The patient showed positive drug response and after the double-blind phase was over and the patient was shifted to a 1 week no-drug schedule, she called her physician 3 days later describing typical withdrawal reactions which included gastrointestinal symptoms, increased sensitivity to sound and light, increased anxiety, distress, and marked lethargy. The patient was seen at once and the psychiatrist evaluating the patient was so sure about the drug the patient was receiving that he did not even request a break of the code. He placed the patient on alprazolam for 2 weeks followed by a slow medication taper without any problems. When the study was completed and the code broken, everyone can imagine our surprise when we learned that the patient had been on placebo the whole time.

In summary, let me state unequivocably my firm belief that no psychiatric treatment method, be it a pharmacological or nonpharmacological one, be recommended for general use unless controlled studies have been conducted which clearly confirm the treatment's claimed efficacy. And in the evaluation of psychopharmacological agents this should always include at least several placebo-controlled studies, some of these also including a standard drug as a third treatment group. This statement holds true not only for the assessment of new agents in the treatment of anxiety, depression, insomnia, pain, and Alzheimer's disease, but also schizophrenia. In all psychiatric conditions, such nondrug factors as milieu change, amount of support, social and familial manipulations and many others, including the mere passage of time, do exert important treatment effects, effects which have to be controlled for in psychiatric drug trials.

Scientific and Ethical Considerations in the Use of Placebo Controls in Clinical Trials in Psychopharmacology

Gerald L. Klerman, M.D.[1]

On the occasion of the 25th anniversary of NCDEU, it is appropriate to reconsider the issues involved in the use of placebo controls in clinical trials in psychopharmacology. In the current scene, these issues involve scientific considerations and ethical problems.*

Historical Background

The theoretical and statistical basis for clinical trials had been established for many years, particularly with the work of Fisher and other British statisticians. However, it was not until after World War II that the pace of clinical research accelerated, and clinical trial designs became increasingly utilized in medicine, notably in the evaluation of treatment for cardiac problems, specifically angina pectoris, and in the evaluation of treatments for tuberculosis. Government agencies played a major role in this expansion of the use of clinical trial designs, particularly the Veterans Administration in the United States and the Medical Research Council (MRC) in the United Kingdom.

Although a few clinical trials were attempted in psychiatry in the 1930's and 1940's to assess the claims for the efficacy of convulsive therapy, insulin coma therapy, and even prefrontal lobotomy, it was not until the advent of the newer psychopharmacologic agents in the mid–1950's that clinical trials became involved in psychiatry. The rapid arrival of chlorpromazine and other phenothiazine derivatives, rauwolfia and its derivatives, and meprobamate led to intense controversy and, in partial response to that controversy, a number of controlled clinical trials were begun.

Government agencies in both the United States and the United Kingdom played a major role in organizing these trials of psychiatric drugs. In the United States, credit should be given to the Veterans Administration and also to the National Institute of Mental Health (NIMH). In the United Kingdom, the Medical Research Council initiated a number of trials.

At NIMH, the creation of the Psychopharmacology Service Center in 1956, under the imaginative leadership of Jonathan O. Cole, M.D., stimulated the development of trials, notably the Collaborative Study on the Assessment of Phenothiazines (Cole et al., 1964).

In the 1950's and early 1960's, the scientific issues of design and methodology were in the forefront. There was considerable debate as to the necessity for controlled trials. Experienced clinicians argued that controls were not necessary since they could distinguish placebo effect from drug effect and, by knowing the individual patient well, could identify the specific pharmacologic actions. Doubts were also raised about the feasibility of conducting clinical trials with psychiatric patients because of the variability of their responses, the important role of psychosocial influences on symptom fluctuation, and the absence of objective measures of psychopathology.

These issues dominated discussions in the 1950's and early 1960's, but rapidly receded through the late 1960's with the growing evidence for the efficacy of drugs and the value of clinical trials (Levine et al., 1971).

A powerful governmental impetus to the application of controlled clinical trial designs came in 1962 with the passage of the

*Dr. Rickels (this issue) has addressed the major historical background.

Kefauver-Harris Amendments to the Federal Food, Drug, and Cosmetic Act. It took 10 years for the Food and Drug Administration (FDA) to implement fully the provisions of that act. During that period, the National Academy of Sciences established the Drug Evaluation Scientific Inventory project (DESI) to review all classes of drugs approved prior to the 1962 Act, including psychopharmacologic agents. That panel was chaired by Daniel X. Freedman, then at the University of Chicago. In addition, the FDA commissioned the American College of Neuropsychopharmacology (ACNP) to participate in the guideline projects, and members of the psychopharmacologic community, through ACNP, participated in developing guidelines for the evaluation of antipsychotic, antidepressant, and antianxiety agents. These guidelines reaffirmed the necessity for controlled studies and, in particular, mandated the use of placebo controls.

By the mid-1970's, the scientific issues around the use of placebo controls subsided and ethical issues began to emerge. In the current scene, the ethical issues are predominant. There are often confounding scientific and ethical issues. Ethical concerns sometimes serve as a rationalization for avoiding the use of placebos. This is particularly so in individuals who advocate evaluating a new drug against some available drug in a two-group comparison design without necessarily using placebo.

The Scientific Consensus

It is useful at this point to restate the consensus arrived at in the 1960's. Why use placebos? Why use control groups? The placebo control group represents a control for a "package" of effects which potentially could obscure and confound the demonstration of drug efficacy.

Do placebo controls control for package of effects? These include:

1. The passage of time, particularly for patients with disorders with an inherent tendency to remit, such as acute depressive reactions, transient stress responses, adjustment disorder with mood, etc.

2. The increased attention given to the patient by the warmth, sympathy, and encouragement of the medical and nursing staff.

3. The patient's expectations and hope for improvement.

4. The psychosocial consequences of being legitimized in the sick role being given the role of patient, often has profound effects on family relations by recasting the patient's problems and behavior into an illness explanation rather than his actions being judged as badness.

In addition, there may be extensive cognitive reframing of the meaning given by the patient to his or her experience through the research interviews, rating scales, and checklists. Being asked to reconstruct the sequence of symptoms and events often gives patients a sense of meaning to the experience and serves to demystify the sequence of symptoms, distress, etc.

The multiple rating scales and checklists may serve as a form of self-monitoring, a behavioral technique shown effective in many forms of behavioral psychotherapy.

There are at least two other important reasons why a placebo control is desirable from a scientific point of view.

1. The placebo control serves as a means of calibrating the skills of the research group. In psychopharmacology, the research group and the research setting are the "instruments" for the detection of change, similar to the use of chemical instruments, such as gas chromatograph in blood assays for drugs. Just as the chemical laboratory would need to calibrate its instruments against blanks and standards on a periodic basis to maintain quality control, so the research group needs to calibrate itself to establish its sensitivity. Can this research group detect the difference between an active drug and a placebo or no-pill? Are they treating a patient population that is sensitive to drug effect? Are they adequately trained? Are they using assessment devices, including rating scales and checklists, which are capable of detecting change? There, the placebo control serves as a test of the sensitivity of the research group.

2. A placebo-washout period between the time the patients enter the study and the initiation of active drug treatment is particularly important in the current scene. In our socie-

ty, a high percentage of individuals are taking psychoactive drugs, including benzodiazepines, sedative-hypnotics, and recreational drugs. Very often patient experiences are symptomatic effects due to the pre-existing drugs, and the placebo-washout period establishes a new baseline for the amount of drug effect. This may particularly be the case in chronically ill patients who are treatment resistant, for example, the improvement noted in chronic schizophrenics when they were discontinued from maintenance treatment with neuroleptics by Paul and Lentz (1977).

Distinguishing Nonspecific Effects From Placebo Effects

Sometimes these effects are called "nonspecific" effects; sometimes nonspecific effects are equated with placebo effect.

It is desirable to distinguish within the package of nonspecific effects, that effect which may be related to pill-taking (i.e., the placebo effect). The optimum way to assess this would be a drug trial in which there was a placebo-pill group, as well as a no-pill control group and an active drug group. Where drugs and psychotherapy are being compared, there may be important reasons to employ both a placebo and a no-pill group, as has been argued by Hollon and DeRubreis (1981). Only a very few such efforts have been undertaken, most notably the trial of drugs and psychotherapy in depression by the Boston-New Haven Collaborative Group (Klerman, 1974). In that study, no effect of placebo pill-taking was noted above the no-pill situation, suggesting that there is no specific effect due to the expectation of pill-taking and prescription over and above the other nonspecific effects listed above.

Ethical Considerations

In recent years, ethical considerations have gained importance in designing trials of illnesses for which standard treatments exist, as in psychoses, or where the control group may have potential adverse effects, as, for example, "sham" electroconvulsive therapy (ECT) with induced unconsciousness, ethical considerations may preclude the use of placebos.

Space does not permit a full discussion of the constraints upon demonstration of efficacy that follow from the ethical restraints on the use of placebo groups. However, it is pertinent to identify a number of solutions that have been proposed and utilized.

On a nonscientific basis, the situation would be improved by increased interaction and communication between investigators and the Institutional Review Boards (IRBs) at their institutions. This communication should be extended to the national scene. A future conference should be planned to provide systematic interchange between scientific groups and representatives of review committees, such as the Editorial Board of IRB, or an organization such as Physician's Responsibility in Medical Research (PRIMR). This might make a useful topic for a future NCDEU meeting.

At the scientific level, a number of design options have been proposed. One is the use of a "treatment on demand" as a control. In this situation, patients are told that treatment is available to them as they feel their symptomatic state may require. Patients who exceeded a certain number of calls or visits per week are then considered treatment failures and removed from the protocol, but treatment is provided to them on a clinical basis. This option has been employed in a study on drugs and psychotherapy in acute depression (Richman et al., 1980).

Second, some investigators have allowed very liberal clinical judgment for removal from the study. Here the decision lies with the clinician. The clinician can remove the patient from the study because of concern for failure to improve, worsening in clinical condition, or adverse effects. In this design, the rate of removal from the study becomes an indirect measure of efficacy of the treatment. At the same time, the patient's clinical needs are adequately met. In order for this design to be adequately executed, it is desirable that the criteria for removal be operationally specified in advance, preferably in quantitative terms. The three categories mentioned above (failure to improve, worsening in clinical condition, adverse effects) are subject to marked variation in clinical judgment and prior agreement as to criteria in terms of rating scale change, or symptomatic or social functioning to enhance reliability and reduce variability among clinicians when the study is conducted across sites or with multiple clinicians at a single site.

Third, is the use of constructive designs. Where an established standard treatment exists, such as neuroleptic treatment for schizophrenics, constructive designs can be used. In these designs, all the patients receive the established treatment and subgroups receive the new treatments. The assumption is that the combination of the standard treatment plus the new treatment will have an additive, synergistic (cocktail) effect (Klerman, in press).

Three recently designed studies employ constructive designs in an interesting way. One, the NIMH study of strategies for the treatment of schizophrenia (Schooler and Keith, unpublished), employs a design in which all patients receive neuroleptic medication; however, the drug sample is divided into a high-dose group and a low-dose group and the design also allows for comparison of two forms of psychosocial intervention, including family psychoeducational efforts. Thus, there is simultaneous exploration of variation in drug dose as it may interact with psychosocial intervention. However, all patients are receiving neuroleptic medication based on the prior demonstration of the efficacy of neuroleptic medication.

Second, the Philadelphia study of drug dependence in the treatment of opiate dependent individuals (Woody et al., 1983) has reported the efficacy of professional psychotherapy. In this study at the Philadelphia VA Hospital, opiate dependent patients in the trial all received a "standard package" consisting of methadone maintenance plus psychotherapeutic counseling by ex-addict peer counselors. One-third of the sample received only the standard treatment, one-third received professional psychotherapy of the cognitive-behavioral type developed by Beck et al. (1979), and the other third received psychoanalytically derived supportive-expressive therapy (Luborsky, 1984). In this study, the two forms of professional therapy showed significant advantage over the standard treatment of methadone maintenance plus peer counseling.

Third, Mavissakalian (1984) has recently reported on treatment of agoraphobia in which the standard treatment involved all patients receiving instruction for in-vivo exposure. Exposure via instruction had previously been shown to have moderate efficacy, helping about 50 percent of patients with agoraphobia. Imipramine or professional exposure therapy was then compared. These constructive designs assume prior demonstration of the efficacy of the standard treatment. The standard treatment may be a drug treatment; as in the case of the schizophrenia study, the standard treatment was a neuroleptic. The standard treatment may be psychotherapy, as in the case of Mavissakalian's study of phobia, or the standard treatment may be a combination as in the Woody study, where the combination of methadone maintenance plus ex-addict peer counseling was the standard.

Conclusions

A scientific consensus has emerged as to the necessity of placebo controls in psychopharmacology. A similar consensus does not exist for psychotherapy research. It is of interest that the placebo group in psychopharmacology includes a package of social psychological factors such as the sick role, and the interaction between patient and therapist expectations. For the psychotherapy research, it is this very package of effects which is among the specific component of psychotherapy and which merits dismantling strategies (Kazdin, in press; Wilkins, 1984).

However, in the current context, the predominant issues regarding the use of the placebo controls in psychopharmacology are not scientific but ethical. The interactions between scientific and ethical considerations continue to be an important area in clinical psychopharmacology. The need exists to explore more fully the principles upon which ethical considerations constrain the use of placebo and in those instances where the ethical issues are predominant, alternative designs need to be developed. A number of promising constructed designs are being employed in conditions where standard treatments exist. The other major design innovation is the use of patient or clinician judgment for removal from the study and using the rate of removal as an indirect measure of efficacy. NIMH should consider the desirability of a conference to promote communication between bioethicists and leaders of IRBs on one hand, and clinical psychopharmacologists, statisticians, and methodologists on the other. Such a conference could provide the arena for intense discussion of unresolved problems and, hopefully, modes of their resolution.

The Placebo Control in Clinical Trials (A View From the FDA)

Paul Leber, M.D.[1]

In many quarters, placebo controls are maligned; yet, their use is virtually indispensable to the intelligent assessment of efficacy of most psychopharmacologic drug products. It is, therefore, especially gratifying to find the use of placebo resoundingly endorsed by two distinguished investigators, Drs. Rickels (1986) and Klerman (1986). Indeed, their arguments for the use of placebo are so compelling and complete that this discussion must retrace ground they have already traversed.

Federal regulations governing drug product development recognize five types of control conditions that may be employed in clinical investigations intended to meet the regulatory standard of "adequate and well-controlled" investigations (21 CFR 314.126), the standard that must be met if a trial is to be accepted as a source of "substantial" evidence of drug product efficacy. The five control conditions (i.e., placebo, dose-comparison, no treatment, active, and historical), however, vary considerably in the number and nature of assumptions required for their interpretation and, therefore, in their degree of reliability.

The historical control is highly unreliable (Sachs et al., 1982) and, therefore, considered a control of last resort in almost every area of drug development. Because the no-treatment concurrent control does not allow blinding, its usefulness in psychopharmacologic drug development is minimal. Thus, only placebo, dose-comparison, and active control designs which employ prospective and concurrent randomization of experimental and control treatments are of much use in psychopharmacology. In theory, these three designs are capable of generating equivalently persuasive evidence of efficacy; a demonstration of a difference (in the appropriate direction) between experimental and control treatments, provided it cannot be attributed to fraud, bias, or chance, must be attributed to a pharmacologic effect of the experimental drug.

However, as commonly used in psychopharmacologic drug development programs, only placebo-controlled trials have regularly provided this sort of unambiguous evidence of efficacy. Active control investigations rarely document the superiority of an experimental treatment to standard drug and, to date, experience with fixed-dose response designs is so limited that it is impossible to make any informed judgment about their potential usefulness. From a regulatory vantage point, therefore, the placebo control trial has been an indispensable tool for the assessment of psychopharmacologic drug product efficacy.

What accounts for the value of the placebo control? The placebo control allows one to distinguish between true drug effects and improvements due to 1) spontaneous remission; 2) inconstancy of illness course (i.e., if subjects are recruited at a time of symptomatic exacerbation, their subsequent improvement may reflect only a regression to the mean); 3) biased (intentional or unintentional) assessment of outcome; and 4) nonpharmacologic effects of the treatment arrangement or contract (i.e., the placebo effect, per se).

Do placebo control trials have any faults? Of course. One concern is that the very possibility of assignment to a pharmacologically inert treatment may alter the behavior of subjects and investigators in ways that may seriously compromise the external validity of the study. In particular, the chance that placebo may be assigned can affect 1) sample selection (e.g., the very ill may be systematically excluded), and 2) trial conduct (e.g., investigators may be more willing to drop patients who do not immediately respond to their assigned treatment than they would in a trial employing only "active" drugs).

Another shortcoming of studies that employ only a placebo control is that they fail to provide any data about comparative efficacy and safety. While such data are not germane

---

[1] Food and Drug Administration, Rockville, MD 20857.

to a regulatory judgment concerning efficacy, knowledge of the relative utility and risk of treatments is important for drug labeling. Moreover, the interpretation of a trial that fails to discriminate between an experimental drug and placebo can be markedly affected by knowledge of the performance of a standard treatment in that same trial. In particular, if a study fails to discriminate between the investigational agent, standard drug, and placebo, the study can be more readily discounted (i.e., it can be given lesser weight) in the agency's overall assessment of evidence bearing on the experimental drug's efficacy.

Consequently, the clinical trial design that employs placebo, standard drug, and investigational drug is an ideal marriage of the placebo and active control designs. Placebo provides an estimate of what would have been had no pharmacologic treatment been given. Standard drug provides an estimate of both the intrinsic responsiveness of the patient sample to pharmacologic treatment and the sensitivity of the assay system (i.e., the investigator and his assessment methodology). The design offers the same sort of reference points as do the blank and standard solutions in a spectrophotometric analysis.

Overall, it seems fairly obvious that the placebo alone or, still better, combined with a standard drug control, is an essential tool in psychopharmacologic drug development.

This favorable view of placebo, however, is not universally held. Objections to its use have been raised on both practical and ethical grounds.

One practical objection to placebo is that it retards subject recruitment. Physicians and patients are often reluctant to forego or delay treatment with an effective drug, or even a putatively effective one, to use placebo. The objection, however, cannot be fully assessed without reference to the implied comparison; namely, what experimental design is it easier to recruit for? Unless the alternative design has a utility equivalent to the placebo design, the advantage is illusory.

Indeed, many of those who raise objections to placebo appear to assume, albeit incorrectly, that the active and placebo controls provide equivalent protection against error. If this were true, of course, there would be no justification to employ placebo. In fact, however, active controls, as commonly used in psychopharmacology, rarely provide any useful information about efficacy.

When an active control trial fails to distinguish between the effects of an experimental agent and a standard "active" control, it does *not* prove that the two drugs are equally effective. The same result might occur if both treatments were inert, if the study had inadequate statistical power, or if the study were carelessly conducted. Thus, those who argue that a finding of no difference is evidence of efficacy rely upon a series of sanguine assumptions about the conditions under which the active control study was conducted. Many of these assumptions may be unwarranted (Leber, 1985). In particular, the assumption that a standard psychopharmacologic control treatment is "active" in a particular experiment is especially tenuous. Anyone familiar with the nature of psychiatric symptoms, their intrinsic variability, and the variable nature of treatment response among psychiatric patients will recognize why.

Furthermore, the ability to detect a difference between treatments is influenced by both the size of a study and the quality of its conduct. In trials where the goal is to demonstrate a difference, it is in the interest of those who conduct them to increase power and maintain high standards of trial execution. In contrast, in trials where the aim is to fail to show a difference, the incentives, as Temple has noted (1982), are reversed.

Thus, any potential advantage in recruitment rate offered by the active control design would seem to be completely offset by its epistemological flaws. There is no advantage in carrying out a worthless study rapidly!

As noted earlier, objections to placebo are also made on ethical grounds. It seems likely that the failure to recognize the intrinsic flaws of active controls may contribute to the debate about the "ethics" of placebo use. That is, many who object to the use of placebo controls on so-called ethical grounds may do so based on the false belief that the active control is a reasonable alternative to the placebo.

In any case, there are those who believe that the use of placebo is unethical in settings where established treatments exist for the condition for which an experimental drug is being developed (Way, 1984).

This discussant finds this view inconsistent. If one believes that it is unethical to deny a patient immediate access to a known effective treatment in order to assign him to placebo, it should be equally unacceptable to delay his access to definitive treatment in order to assign him to an investigational agent which may not only be ineffective, but dangerous.

In summary, the placebo control is an indispensable tool. If it (or some reasonable substitute for it such as the fixed dose, dose-response control) were not available, we would have to approach each new drug with the skepticism expressed by the 19th century physician who advised his colleagues ". . . to treat as many patients as possible with the new drugs while they still have the power to heal." (Trousseau, quoted by Benson and McCallie, 1979).

Placebo controls are our surest protection against fads and fashions that come and go in pharmacology, against the reckless claims of therapeutic enthusiasts, and, most important, against our own mistaken beliefs and prejudices.

Pharmacological Treatments of Schizophrenia

George M. Simpson, M.D.[1]

As this is an anniversary meeting, it seems appropriate to give some information about the early clinical drug evaluation units (ECDEU), later the NCDEU. This group of investigators was created by the Psychopharmacology Research Branch (PRB) and was exceptionally important for the development of psychopharmacology in this country. In the early days of drug studies, it was reported (perhaps somewhat tongue-in-cheek) that one might receive large bottles of pills, give out handfuls of them, and report that "this is great stuff," and that was the study. Indeed, I once saw an investigator who had a pocket notebook and less than half a page of medium-size handwriting was the sum total information for each patient on his clinical trial. I might also add that his records were much superior to the other studies that I had occasion to see at that time. My own work at that time involved the notion that resting endocrinological measures would predict outcome in major mental illness, specifically schizophrenia. This was funded in the late 1950's by the PRB under the title "Research in Endocrinology and Drugs," later "The Red Project." Spin-offs from this study were trials of triiodothyronine as a treatment in schizophrenic patients with low thyroid tests who were also receiving neuroleptics, trials of Enovid in female patients who showed regular exacerbations of their psychotic symptoms thought to be associated with their menses, papers on the effects of antipsychotic drugs on reproductive function, effects of antidepressants on genito-urinary function, and a publication that showed an increase in spermatogenesis associated with the administration of a monoamine oxidase inhibitor (MAOI). On further consideration, this latter was most likely related to the fact that the two colleagues who happened to get depressed and who had been measuring their own semen count, motility, and morphology weekly for several years also drank quite a bit. The MAOIs may have been less the agent for change than the withdrawal of alcohol which was ordered during the course of this treatment.

At all events, these and other clinical trials outside the endocrinological research ward interested me and led to my applying for a grant and becoming an ECDEU member. There were many drugs available at that time and several new drugs were evaluated in the course of any 1 year. Multiple rating scales were used, many of which are seldom used today. It is not that they were poor scales but that, as ECDEU grew, the Psychopharmacology Research Branch (PRB) developed a data analysis capability, and some standardization of rating scales was essential. Thus, the Brief Psychiatric Rating Scale (BPRS) and Nurses' Observation Scale for Inpatient Evaluation (NOSIE) became standard scales. Many individual and cooperative studies were carried out by these investigators, and the science of clinical trials received a hefty shot in the arm. Diagnosis was, if not frowned on, certainly at a very primitive level in the early 1960's. One saw some very raucous and intrusive people labeled schizophrenics who were textbook manics. Perhaps because of this lack of interest in diagnosis, there were some peculiar ideas about drug actions. The idea of target symptoms was clearly a good one and was incorporated into rating scales, but there was also a notion that target symptoms were individual items and did not belong in groups to syndromes or were unrelated to diagnosis. Thus, the notion that there might be drugs specifically for hallucinations, for example, resulted in a drug marketed for that purpose—Frenquel.

Many clinical trials at this time at ECDEU units studied new drugs in chronic schizophrenic patients. The dramatic effect of chlorpromazine in an open study, coupled with the large number of hospitalized pa-

---

[1] The Medical College of Pennsylvania, Philadelphia, PA 19129.

tients, made this a reasonable strategy. Hospitals had many patients who could not be discharged and who had many positive symptoms when off drugs and made mild to moderate improvement on neuroleptics. Studies invariably took 6, 8, or 12 weeks of active treatment with several weeks of no drug or placebo before and after treatment. Weekly NOSIE, BPRS, Global, and other scales were employed. It was not difficult to demonstrate in such a study that a drug was an active antipsychotic agent. All of the current antipsychotics were first tested in this fashion with the initial findings confirmed in placebo-controlled studies. It is not too surprising, if we consider that all of these drugs were developed from a similar animal model developed after the discovery of chlorpromazine, which worked so well that a variety of chlorpromazine-like drugs was developed. After the production of many, many drugs that differed in their side effects rather than in their therapeutic effects, this procedure reached a dead end. The number of new drugs diminished. There has not been a new antipsychotic drug on the U.S. market since loxapine (1975)—one of the last drugs studied collectively by ECDEU investigators. ECDEU researchers in effect received funds as an investment in them rather than in specific projects. The drop in the number of new drugs left more and more investigators with time to devote to their own pet projects which soon resembled R01 studies, e.g., our staff was involved in studying plasma levels of neuroleptics and in studying tardive dyskinesia at the time the NCDEU change took place.

During this time, psychopharmacology progressed enormously—the sophistication of the methodology, the concern with selection of patients, diagnosis, new rating scales, inter-rater reliability, validity, etc. To an extent, the science of clinical trials which was practically nonexistent in psychiatry was now better developed in psychiatry than in any other medical specialty. Individual investigators also asked many questions about conventional drugs and produced much of the knowledge that supports present-day practices. For instance, during this period we showed that in a double-blind, controlled study one- versus three-times-a-day neuroleptic medication was equally efficacious and resulted in no increase and perhaps even a decrease in side effects if the single dose was all given at bedtime. Later, we studied the same phenomenon but also measured plasma levels. We studied fluphenazine decanoate and showed that it was active at 12.5 mg every 2 weeks. We showed that patients in general responded similarly to repeated administrations of medication, that patients who gained weight did so on each occasion, and patients who did not gain weight did so on both occasions. We showed that the immediate symptoms of withdrawal of antipsychotics were mainly related to the concomitant withdrawal of anti-parkinson agents. Therefore, a patient receiving a neuroleptic plus an anti-parkinson agent should not have both withdrawn simultaneously; the anti-parkinson agent should be continued for at least 1 week in order not to have an upsurge of extrapyramidal reactions. In 1968, we studied "the behavioral and anti-epileptic effects of an iminostilbene derivative," one of the earliest studies of Tegretol in a psychiatric population; and in 1967, a preliminary evaluation of the sedative effects of Catapres, a new antihypertensive agent in chronic schizophrenic patients. A series of papers on extrapyramidal side effects (EPS) resulted in the development of a rating scale for EPS. From this and other studies came our interest in trying to cut down the very high dose of drugs that psychiatrists used and continue to use. In these studies, it appeared that doctors used 300 percent more neuroleptics than were required. In the 1960's began the studies of lithium, studies of naltrexone in chronic schizophrenia, studies of antipsychotics in the elderly, studies with clozapine, and so on. Each ECDEU would have a similar range of different studies that they carried out, all of which added to our knowledge of psychopharmacology.

Nearly all of the investigators were active in teaching and training and so, to a large extent, these units reached a stage where they were perhaps no longer necessary, i.e., there were groups of young psychiatrists who were now being trained in psychopharmacology, the journals were replete with good studies to be read in journal clubs, etc. The introduction of clozapine raised new hopes for the type of different drug that everyone had been looking for, and this remains a not-impossible dream but certainly an unrealized one. In the meantime, use of neuroleptics has advanced the treatment of schizophrenia. It is safe to say that without neuroleptics, social psychiatry and the community mental health movement would have had great difficulties in coming about. The surge of interest in psychosocial treatment of schizophrenia highlights this, since clearly psychosocial interventions are helpful but are not very helpful in the absence of neuroleptic agents. Thus, this anniversary of the ECDEU truly represents the end of a cycle in the search for new treatments in schizophrenia. A substantial advance has been made in the treatment of schizophrenia and, while we have far to go, I feel secure that NCDEU investigators will be in the forefront of the advances to come.

Research Methodology and the Pharmacotherapy of the Chronic Schizophrenias[1]

Thomas A. Ban, M.D., William Guy, Ph.D., and W.H. Wilson, Ph.D.[2]

Introduction

Schizophrenic disorders occur in 0.86% of the general population. This implies that 86 out of 10,000 people randomly chosen from the general population will develop a schizophrenic disorder during their lifetime (Tsuang & Vandermey, 1980). Almost half of all patients diagnosed as schizophrenic will need long-term treatment, and it has been estimated that 30 to 60% of all new long-term patients suffer from one or another form of schizophrenia (Mann & Cree, 1976). There is evidence that 15% of patients who are diagnosed today as suffering from a schizophrenic disorder will become chronically hospitalized at some time in the future. Consequently, it is estimated that one-third to one-half of all psychiatric beds, i.e., one-sixth to one-fourth of all hospital beds—since nearly 50% of all beds are psychiatric—are occupied by schizophrenic patients (Todd et al., 1977).

The prevailing treatment modality for patients with chronic schizophrenia is pharmacotherapy with neuroleptics. This is to the extent that, in a multi-national survey carried out in 768 chronic hospitalized schizophrenic patients, 739 or 96.2% were treated with one or more of 33 different neuroleptics. The total population of this study was contributed by nine centers geographically located in eight countries (Tables 1 and 2) (Ban et al., 1984b).

In spite of their extensive use, it is difficult to demonstrate the therapeutic effectiveness of neuroleptics in chronic schizophrenic patients. This may be due to the lack of sensitive instruments for the assessment of change in this population. An alternative possibility is that chronic schizophrenia consists of a biologically heterogeneous population. In favor of this latter contention is the fact that not every schizophrenic patient shows a similar response to neuroleptics.

TABLE 1

Number and Percentage of Patients Receiving One or More Neuroleptics

Country	*N*	Neuroleptic *N*	Neuroleptic %
Brazil	95	71	74.7
Hungary	59	58	98.3
Italy	93	90	96.8
Japan	200	200	100.0
Nigeria	10	10	100.0
Panama	86	86	100.0
USA	150	149	99.3
Yugoslavia	75	75	100.0
Total	768	739	96.2

TABLE 2

Thirty-Three Neuroleptics Employed in Eight Countries (rank order)

1–11	12–22	23–33
Haloperidol	Promazine	Methylperidol
Chlorpromazine	Clothiapine	Oxypertine
Levomepromazine	Loxapine	Mesoridazine
Thioridazine	Pimozide	Alimenazine
Fluphenazine	Carpipramine	Trifluoperidol
Perphenazine	Perazine	Clopenthixol
Thiothixene	Reserpine	Molindone
Trifluoperazine	Floropipamide	Spiperone
Sulpiride	Fluspirilene	Moperone
Clozapine	Butaperazine	Fluphenazine Decanoate*
Propericiazine	Flupenthixol	Fluphenazine Enanthate*

*The long-acting preparations are not included in the ranking.

Demonstration of Therapeutic Efficacy

Demonstration of therapeutic efficacy is one of the prerequisites for the introduction of a new treatment modality into clinical practice. For drugs which are not causal treatments for a particular disease, e.g., neuroleptics for schizophrenia, this represents a methodological problem which includes the development of an appropriate experimental design and the employment of a discriminative instrument for the measurement of change. It is important that the assessment instrument employed in the measurement of change have the necessary sensitivity to demonstrate differences between the new treatment and the untreated course of the disease (placebo) at the accepted level of probability.

---

[1] This study was supported in part by USPHS Grant MH-35720 from the National Institute of Mental Health.

[2] Department of Psychiatry, Vanderbilt University Medical Center, Nashville, TN 37217.

The most frequently employed instrument in the assessment of neuroleptic-induced changes in chronic schizophrenic patients is the Brief Psychiatric Rating Scale (BPRS) (Overall & Gorham, 1962) which consists of 18 items scored on a 7-point scale of intensity.

Since an essential prerequisite for the usefulness of the BPRS in chronic schizophrenic patients is the necessity that the majority of the 18 items (symptoms) be present in a considerable percent of the target population, we have reviewed our data to determine the presence of 18 psychopathological symptoms corresponding to the BPRS items in the same population of 768 patients (Ban et al., 1985).

Data were collected with a specially devised instrument, the Psychopathological Symptom Profile (PSP), developed from the Psychopathological Assessment form of the second edition of the AMP-System by adding items from the Present State Examination (Wing et al., 1974), the Schedule for Affective Disorders and Schizophrenia (SADS) (Spitzer & Endicott, 1978), and on the recommendation of special consultants. The PSP consists of 176 psychopathological symptoms and includes most items of the Psychopathological Symptoms section of the English edition of the AMDP–III System (Guy & Ban, 1982). Each item is followed by a brief definition and is scored from 0 to 3, indicating whether the symptom is definitely absent (0), probably absent (1), probably present (2), or definitely present (3). Accepting scores 2 or 3 as "present," it was revealed that, of the 176 symptoms of the PSP, 33 were present in at least 40% of the 768 patients (Table 3). We chose the 40% as cutoff point on the basis that any symptom present in a lower percent would not be a useful item in the assessment of change. As shown on Table 4, 8 of the 18 BPRS items are included among the 33 most frequently encountered symptoms of the PSP. While these represent some of the most frequently encountered symptoms of schizophrenia, it is clear that there are a number of significant symptoms which are simply not encompassed by the BPRS. A differently structured instrument would be more suitable in the assessment in order to avoid the possibility of covering up therapeutic changes (Type II or β error) resulting from the administration of neuroleptic drugs.

TABLE 3

Psychopathological Symptom Profile (The 33 Items Present in 40% or More of the 768 Patients)

Rank	Item	*N*	%
1	Lack of insight	717	93.4
2	Blunted affect	632	82.3
3	Asocial behavior	606	78.9
4	Delusions	561	73.0
5	Autistic	553	72.0

Shortcomings of Classification

Introduction of neuroleptics, the most effective single treatment modality employed in chronic schizophrenic patients, has brought attention to the differences in therapeutic responsiveness among patients. In spite of this recognition, which suggests that chronic schizophrenia consists of a biologically heterogeneous population, examination of the nature of this heterogeneity, by studying the natural course of the disease with special emphasis to the end-state syndromatology of patients, has been given little attention. This is especially surprising since there is little, if any, evidence that patients with different types of schizophrenia as classified by the Diagnostic and Statistical Manual—3rd ed., 1980 (DSM–III) or ICD–9 respond differentially to neuroleptic drugs, while there are indications for differential responsiveness in the different subtypes (end-states) described in Leonhard's (1979) classification of chronic schizophrenias. This complex classification which distinguishes 19 distinct syndromes belonging to two groups of disorders within the schizophrenias has shifted emphasis from the acute to the chronic forms of the illness. Leonhard maintains that schizophrenic disorders can best be studied after the acute manifestations common to all schizophrenias have subsided and the illness has progressed into its disease-specific final form (Ban, 1982) (Table 5).

By employing Leonhard's classification, Fish, as early as 1964, found that 117 out of 123 nonsystematic schizophrenics (95%) showed a favorable therapeutic response, while only 289 out of 351 systematic schizophrenics (69%) showed a favorable response. From both a practical and a theoretical point of view, however, the important findings were that among the nonsystematic patients, the favorable therapeutic response was rated marked to moderate in 79% of the treatment responsive patients, while among the systematic patients only 23% were so rated. Fish also noted that, among the nonsystematic patients, those suffering from periodic catatonia responded less favorably than patients with affect-laden paraphrenia and especially

TABLE 5

Leonhard's Classification of Chronic Schizophrenias

Nonsystematic			Systematic		
Cataphasia	Affect-laden Paraphrenia	Periodic Catatonia	Paraphrenias	Hebephrenias	Catatonias
			Phonemic	Autistic	Parakinetic
			Hypochondriacal	Eccentric	Proskinetic
			Confabulatory	Shallow	Speech-prompt
			Expansive	Silly	Speech-inactive
			Fantastic		Manneristic
			Incoherent		Negativistic

cataphasia; among the systematic patients, therapeutic responsiveness was not evenly distributed among the three major classes of illness. Thus, while as many as 40% of the paraphrenics showed a moderate or marked therapeutic response to neuroleptics, only 23% of the hebephrenics and 0.9% of the systematic catatonics showed a similar response.

Corresponding with these findings are our observations and results. We have reported on a patient with the diagnosis of periodic catatonia (febrile catatonia), a nonsystematic subtype, in whom an increase in neuroleptic dosage was associated with exacerbation, a decrease in dosage with amelioration, and discontinuation of medication with remission of psychopathological symptoms (Kelwala & Ban, 1981a). In another case report of two patients with diagnoses of shallow hebephrenia, a systematic subtype, discontinuation of neuroleptic medication had no detectable effect for an extended period (Kelwala & Ban, 1981b). Thus, in our two shallow hebephrenic patients, the usefulness of maintaining neuroleptic treatment was questionable; in our periodic catatonic patient, neuroleptic treatment seemed to have a negative therapeutic effect.

The notion that neuroleptic treatment in certain patients may not just be ineffective but may actually be harmful received further substantiation in our survey of 24 patients treated with lithium/neuroleptic combinations. A common characteristic of these patients was that they had previously shown insufficient therapeutic response to neuroleptic drugs alone. Analyses of data revealed that 9 of 10 patients of the nonsystematic population exhibited a favorable therapeutic response to the combination, while 9 of 14 systematic patients showed no response or an unfavorable therapeutic response. In addition, 5 of the 24 patients developed neurotoxicity during the course of treatment; 2 of the 5 patients were silly hebephrenics and 1 each belonged to the expansive, fantastic, and confabulatory subtypes of paraphrenia. While 5 out of the 14 patients with systematic schizophrenia manifested neurotoxicity, none of the 10 patients with nonsystematic schizophrenia, predominantly affect-laden paraphrenia, developed a similar undesirable response to the lithium/neuroleptic combination (Prakash et al., 1982).

Most important in this context are the findings regarding tardive dyskinesia in our multi-national survey (Ban et al., 1984a). While the overall prevalence rate for the population was 11% when determined by clinical judgment and 13% when determined by the Research Diagnostic Criteria for Tardive Dyskinesia (Schooler & Kane, 1982), within the Leonhard system, rates were found to be significantly lower in the therapeutically more responsive nonsystematic group (4.3%). Furthermore, while within the systematic catatonias, the manneristic subtype (53 patients, 32.7%) attained a prevalence rate of 28% and, within the systematic hebephrenias, the silly subtype (56 patients, 19.1%) had a prevalence rate of 53%, within the paraphrenic category, in the expansive (14 patients, 5.4%) and confabulatory (6 patients, 2.3%) subtypes, tardive dyskinesia was not encountered at all. On the basis of these findings, one may hypothesize that there is an inverse relationship between positive symptoms and adverse effects of the neuroleptic drugs at least insofar as tardive dyskinesia is concerned. Since there is no indication that the action mechanism of neuroleptics would be different in patients belonging to different diagnostic groups, one may speculate that, in the development of tardive dyskinesia, not just the administered drug but the biology of the host also plays an important role.

Concluding Remarks

One of the most important contributions for psychiatry which has resulted from psychopharmacologic progress is the recognition that schizophrenia consists of a biologically heterogeneous population. In view of this, it is rather paradoxical that identification of the role of dopaminergic structure in the action mechanism of neuroleptics and demonstration that neuroleptics produce dopamine receptor blockade led to speculations about the nature of schizophrenia in terms of dopamine excess which, in turn, provided sufficient incentive to develop a large number of "me-too" neuroleptics with similar therapeutic but somewhat different adverse effect profiles.

Ignoring the biological heterogeneity of chronic schizophrenia has created considerable difficulties for research in this population, while its recognition has provided new endpoints for preclinical research especially useful for drug development. One tangible result of this research is the introduction of a new category of psychotropic drugs, referred to as "les produits de transition" (transition compounds) in France.

Included among these substances are amoxapine, a dibenzoxazepine which combines the pharmacologic profile of a tricyclic antidepressant with a neuroleptic; carpipramine and chlorcarpipramine; tricyclic dibenzazepines with butyrophenone side chains; and carbamazepine, an anticonvulsant structurally related to the cyclic antidepressants. While the old methodology should suffice for the demonstration of therapeutic effectiveness of these drugs, the identification of the therapeutically responsive populations may require the employment of new diagnostic assessment instruments.

It is a common contention that psychopharmacology has opened unforeseen possibilities for psychiatric progress leading to a reintegration of psychiatry with other medical disciplines. Reevaluation of psychiatric concepts with consideration to psychopharmacologic contributions could open unforeseen possibilities for psychopharmacologic progress with a shift of emphasis from simple therapeutic efficacy based on statistical probabilities to the identification of therapeutically responsive chronic schizophrenic patients to specific treatment modalities.

Discussion of Dr. George Simpson's Paper on Pharmacological Treatments of Schizophrenia

Solomon C. Goldberg, Ph.D.[1]

In the earlier days of neuroleptics, there was substantial success in treating chronically hospitalized or chronic ambulatory schizophrenic patients. Unfortunately, most of the chronic patients who remain now are treatment resistant. They are a poor sample of patients on which to test new antipsychotic drugs whose mechanism is dopamine blockade. Indeed, they can lead to misunderstandings concerning the effectiveness of neuroleptics in schizophrenia if these patients are employed in a test of neuroleptic effectiveness. Paul's work (1972), in which he failed to find a drug effect in chronic schizophrenic patients, was interpreted by him to mean that antipsychotic drugs in general were not effective in chronically psychotic patients. His error was in generalizing from his results to other situations in which standard antipsychotic drugs are effective in the treatment of many schizophrenic patients. These nonresponders to dopamine blockers become prime candidates for the testing of other antipsychotic agents. We are morally obligated to try to find some treatment that will help these patients. This thought has occurred to a number of investigators, and nonresponsive patients have been tried on such agents as propranolol, alprazolam, carbamazepine, lithium, and *d*-amphetamine.

Before starting a patient on one of these agents, it may be well to confirm that the patient is indeed a nonresponder to standard neuroleptics. State hospitals are notoriously conservative in their dosing strategies because of self-protective policies which prohibit the administration of doses higher than those recommended by the *Physician's Desk Reference.* Prien and Cole (1971), for example, found a substantial number of patients who profited from very high doses of phenothiazines after not responding to standard doses.

In a nearby state hospital we are exploring lithium and carbamazepine for the treatment of neuroleptic nonresponders. There has been no difficulty in getting such patients transferred to our unit. When the patients arrive, they are almost invariably on a variety of medications, and our first step is to taper them from these while building them up on a dose of fluphenazine HCl. The fluphenazine dose is increased for 2 weeks until there is no further improvement or until side effects intervene. So far we have found a few patients who are responders to higher doses of fluphenazine, and they are no longer regarded as nonresponders. Those who do not respond become candidates for our trial drugs, but not on a double-blind clinical trial basis. We feel that this is premature until we generate some hypotheses regarding the characteristics of those who will profit from them. The formal clinical trial of any of the new drugs is postponed until a later time.

If a patient is a complete nonresponder to neuroleptics, he is first put on a trial of lithium alone. If he is a partial responder, he would be put on a combination of lithium and his neuroleptic, which in this case would be fluphenazine. If he does not respond to the first medication, he automatically is then given a trial of carbamazepine. On a case study basis, the characteristics of responders and nonresponders to the different drugs are observed.

Beyond the empirical search for new treatments for nonresponders, there is the more theoretical question of why some schizophrenic patients do not respond to neuroleptics. Here there is another line of research which proposes that the schizophrenic nonresponder shows evidence of organicity. There are now at least two studies, Weinberger et al. (1980) and Schulz et al. (1983), showing an association between enlarged ventricles on the CT scan and nonresponse to neuroleptics. These studies were partly an outgrowth of the Johnstone (1976) and Crow

---

[1] Director of Psychiatric Research, Medical College of Virginia, Richmond, VA 23298.

(1980) hypothesis to the effect that schizophrenic patients with negative symptoms have enlarged ventricles and do not respond to neuroleptics. Murray and his associates (in press–b) go a step further to indicate that the schizophrenic with organic signs has a low genetic loading by virtue of family history for schizophrenia, has a history of birth complications involving signs of asphyxia, and was born in a winter month, implying a greater likelihood of viral infection. Murray, in a recent editorial in *The Lancet* (in press–a), proposes that the time has come to recognize two major etiological types of schizophrenia, a genetically transmitted disorder, and a nongenetic disorder whose etiology is more likely environmentally induced brain damage.

What was begun as an empirical search for new treatments for nonresponders has developed a theoretical facet to try to explain the differences in the characteristics of responders and nonresponders. The heuristic value of the theoretical orientation is that it may be capable of suggesting why some of the new treatments may be effective. For example, Slater's (1963) cases of epilepsy who showed schizophrenic symptomatology might be most treatable with the anticonvulsant carbamazepine. To borrow a phrase from social science, "There is nothing so practical as a good theory."

Baltimore, Maryland

Introduction

Thomas A. Ban, M.D.,[1] and Jerome Levine, M.D.[2]

The multi-center approach has been used in clinical psychopharmacology since the late 1950's. Collaborative studies coordinated by the United States National Institute of Mental Health (NIMH), United States Veterans Administration, and the United Kingdom Medical Research Council contributed to the establishment of proper usage of antidepressant and neuroleptic drugs. Without employing a multi-center approach this would have taken considerably longer, and generalization of the findings would have encountered considerably greater difficulties.

Multi-center clinical trials are particularly advantageous for studying the effect of psychotropic drugs in rare disorders. But even in common disorders such as Alzheimer's type of dementia, if one aims to study a homogeneous sample with progressive deterioration at a particular stage, only in a multi-center clinical trial can one expect to find an adequate number of suitable patients within a reasonable period of time.

International participation adds another dimension to multi-center clinical research. Such studies have at least three essential prerequisites: 1) multidimensional description of patient's condition, because of the possible differences in diagnostic practices among participating centers in different countries; 2) assessment instruments in the measurement of change which are reliable and valid across cultures; and 3) feasibility of coordination for making operational the collaboration.

In this session, findings in three multicenter international clinical trials will be presented, one carried out with an antipsychotic (fluperlapine), another with an antidepressant (fluvoxamine), and the third with an anxiolytic drug (alprazolam).

The topic of the first paper is the AMDP System in International Clinical Trials: A Report on Fluperlapine. The AMDP System stands for Arbeitsgemeinschaft für Methodik und Dokumentation in der Psychiatrie or, in English, Association for Methodology and Documentation in Psychiatry. It was founded in 1965 by a group of psychiatrists from Germany, Switzerland, and Austria to develop a uniform system for the documentation of information which would be useful in both clinical practice and psychopharmacologic research. Since the Psychopathological Symptom Form, the instrument employed in the assessment of change in the AMDP was developed with emphasis on form, i.e., the mode by which the patient encounters contents, and as such is not contaminated by social-cultural contingents, and should be particularly suited for international collaborative psychopharmacologic research.

The first paper dealt with an international multi-center clinical trial with an antipsychotic, the second dealt with an international multi-center clinical trial with an antidepressant. Professor Cassano and his colleagues presented findings from a multi-center international trial comparing fluvoxamine, a specific serotonin reuptake inhibitor with imipramine and placebo. It should be noted that in all the different phases of this study a modification of the Biometric Laboratory Information Processing System usually referred to as BLIPS has played an important role. This system was developed at the Biometric Laboratories of George Washington University in collaboration with the Psychopharmcology Research Branch of NIMH under the leadership of one of us (J.L.). This system, which has played an important role in the development of clinical trial methodology in the United States, has been implemented in Europe, where Dr. Cassano and his colleagues have created an even more versatile system, BLIPS/BDP.

The third paper by Dr. Klerman and colleagues presents, for the first time, the results of Phase I of the Upjohn worldwide panic disorder study.

In addition to the results of these studies, this session demonstrates the different ways in which multinational trials can be organized depending on the roles played by the sponsors, investigators, and the availability of computer-based data documentation and analysis systems.

The AMDP System in International Clinical Trials: A Double-Blind Comparison of Fluperlapine and Haloperidol

B. Woggon,[1] M. Linden,[2] H. Beckmann,[3] E. Krebs,[4] B. Küfferle,[5] B. Müller-Oerlinghausen,[2] B. Pflug,[6] and H.W. Schied[7]

Introduction

One important methodological problem in international collaborative studies is the selection of suitable rating scales. The translation of a psychopathological rating scale is complicated by different concepts of psychopathological symptoms and syndromes in different languages and countries. The Association for Methodology and Documentation in Psychiatry, a collaborative group of German, Swiss, and Austrian psychiatrists, was founded in 1965 and the first AMP manual was established in 1971 (Angst et al., 1969; Scharfetter, 1971). Based on broad clinical experience, many drug trials, and a number of methodological studies, a revision of the AMP system was completed in 1979, called the AMDP System (Association for Methodology and Documentation in Psychiatry) (AMDP, 1979, 1983). The AMDP System is currently available in many languages including German, Croatian, English, French, Russian, Spanish, Japanese, Portuguese, Greek, Italian, Danish, and Dutch.

This paper is composed of two parts: a) a description of the AMDP System; and b) an example of an international collaborative trial: a double-blind comparison of fluperlapine* and haloperidol in schizophrenic patients that utilizes the AMDP System.

Description of the AMDP System

AMDP consists of five integrated parts, each printed on a single sheet of paper: 1) demographic data; 2) life events; 3) psychiatric history; 4) psychopathological symptoms; and 5) somatic signs. The 100 psychopathological symptoms and 40 somatic signs are clearly arranged into groups, an aid for the rater (Tables 1 and 2). It is also possible to add write-in items of specific interest to a clinical trial.

Each symptom can be rated as "absent," "present," or "not ascertained." A symptom is rated as "not ascertained" if reliable information is not available. If a symptom is present, three degrees of severity can be rated: mild, moderate, or severe. This judgment is based on frequency, intensity, and duration of a symptom.

Each rating of psychopathological and somatic symptoms is based on a specified time period, for example 24 hours, and combines

both subjective (reported) and objective (observed) information.

Factor analyses of data from various patient samples have led to the development of subscales representing psychopathological syndromes. For statistical analyses of data from clinical trials, different sets of subscales can be used. A comprehensive monograph in English that describes the system includes studies of subscales, interrater reliability, validity, and sensitivity in drug trials (Bobon et al., 1983).

Double-Blind Comparison of Fluperlapine and Haloperidol

As an example of the use of the AMDP System in an international collaborative trial, we report preliminary results of a double-blind study comparing fluperlapine and haloperidol. Fluperlapine (a dibenzazepine) is very similar in structure to clozapine (Figure 1). In open trials, it showed a strong antipsychotic effect (Angst, 1984).

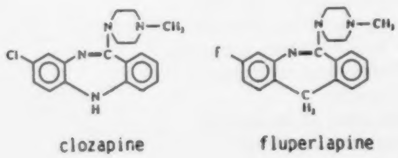

FIGURE 1. Chemical structures of clozapine and fluperlapine.

Seven psychiatric hospitals participated in the study, four in the Federal Republic of Germany, two in Switzerland, and one in Austria. These hospitals are linked to the AMDP and, therefore, the investigators and staff are familiar with and trained in the use of the AMDP System.

The following results are based on data from 120 inpatients who were randomly assigned to treatment with either fluperlapine ($N=60$) or haloperidol ($N=60$). Some patient characteristics are given in Table 3; diagnoses according to the ICD-9 (International Classification of Disease) are given in Table 4. The planned duration of treatment was 28 days. Early dropouts (before day 7) were excluded from the final analysis.

Using a flexible dose regimen, the recommended initial daily dose was 2.5 mg haloperidol or 50 mg fluperlapine, three times a day. Maximum daily dose was 60 mg haloperidol and 800 mg fluperlapine. At the end of the trial, the average daily dose was 23 mg haloperidol (s.d. = 12 mg) and 441 mg fluperlapine (s.d. = 210 mg).

Data analysis was performed at the Department of Psychiatry of the University of Zurich, Switzerland, using a set of 13 subscales (Table 5). Raw scores of the subscales are calculated by adding the included items according to the following values: absent and

*Degkwitz et al., 1980.

not ascertained = 0; mild = 1; moderate = 2; and severe = 3. In order to normalize the distributions, logarithmic transformations were performed for the scores of subscales 1 to 12. The scores of subscales 13 and 14 are nearly normally distributed and do not require transformation. Because the number of items in each syndrome is different (range 7 to 27), all scores are further transformed ($\bar{x}$ = 50, s.d. = 10, range 20-80).

The analysis of the Hallucinatory-Disintegrative syndrome clarifies the antipsychotic efficacy of fluperlapine and haloperidol. The symptoms are listed in Table 6. Table 7 shows mean values and s.d. for the syndrome on each rating day. Significant reduction during treatment occurred in both treatment groups [Friedman's analysis of variance (ANOVA)]. The comparisons between day 0 and subsequent rating days in each group separately indicated a significant improvement beginning on day 3. Because of multiplicity of significance, *t* tests were done; and alpha was adjusted from 5% to 1% (Figure 2).

T tests between the two treatment groups on each rating day revealed no significant differences. An analysis of covariance (ANCOVA) following the model for factorial experiments with repeated measurements, and constant covariates (unequal cell frequencies) was calculated using the scores at day 0 as a covariate (Winer, 1962). No significant differences between the two groups were found.

We predicted a difference in extrapyramidal side effects between the two treatments. The subscale that includes extrapyramidal symptoms is the Neurological Syn-

drome (Table 8). Mean values and s.d. of this syndrome in both treatment groups are listed in Table 9. A significant change over time in the group treated with haloperidol was found (Friedman's ANOVA). Comparison between day 0 and the following rating days demonstrated a significant increase in the haloperidol-treated patients from day 3 onward (Figure 3). *T*-test comparisons at each rating day showed no difference between the groups at pretreatment. From day 3 on, the haloperidol-treated patients had significantly higher values than the fluperlapine-treated group in this syndrome. The ANCOVA showed a significant difference between the two groups.

Summary

Analysis of the Hallucinatory-Disintegrative AMDP Syndrome demonstrates an

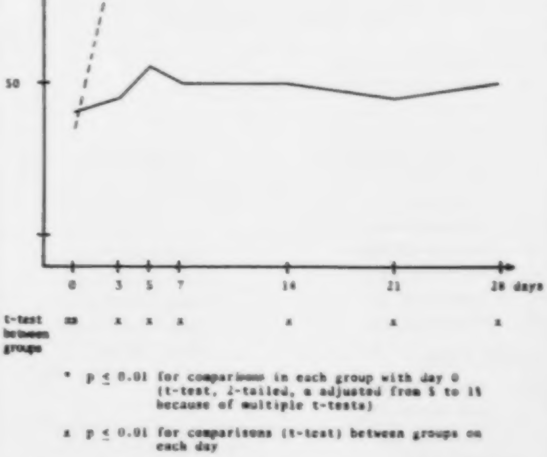

FIGURE 3. Course of the Neurological AMDP Syndrome (mean values).

equally strong antipsychotic effect of fluperlapine and haloperidol with an early onset (day 3). Analysis of the Neurological AMDP Syndrome indicates that haloperidol, in contrast to fluperlapine, causes frequent and strong extrapyramidal side effects.

Use of a Standardized Documentation System (BLIPS/BDP) in the Conduct of a Multicenter International Trial Comparing Fluvoxamine, Imipramine, and Placebo

Giovanni B. Cassano, M.D.,[1] Luciano Conti, M.D.,[1] Gabriele Massimetti, M.D.,[1] Francesco Mengali, M.D.,[1] Jenifer S. Waekelin, M.D.,[2] and Jerome Levine, M.D.[3]

Introduction

When in 1978 Duphar BV, Holland, decided to organize a multicenter international clinical trial with the aim of assessing efficacy and safety of a new selective serotoninergic antidepressant compound, fluvoxamine maleate (FUVOX), the BLIPS/BDP system (Biometric Laboratory Information Processing System/Data Bank for Psychopharmacology), used at the Center for Clinical Psychopharmacology Data Documentation (CCPDD) of the Institute of Clinical Psychiatry of the University of Pisa, appeared to provide the necessary underlying structure for the study by offering an efficient standard data documentation system.

The organizational model that was used for the study provided that the company would maintain their usual role in the selection of sites, monitoring and collecting data, and supplying drugs to the sites. The role of the Pisa center included consultation on the design of the study, choice of the rating scales, and provision of a standardized documentation and analysis system, namely the BLIPS/BDP.

The company provided the raw original data collected from the investigators to the CCPDD. They organized several meetings with principal investigators in which the Pisa center participated, but the Pisa center had no additional contacts with the participating investigators.

The advantages of this organizational model include: a) open choice of sites and investigators (investigators do not need to belong to a previously organized group); b) the company plays its usual role with regard to site selection and monitoring; and c) the BLIPS/BDP documentation and analysis system does not require the use of special purpose (trial specific) rating scales but only the use of a standardized identification block. Therefore, widely used rating scales can be utilized by investigators without the necessity of special training, only checks of interrater reliability. This results in a very cost-effective flexible model which, as we will show, is sufficiently sensitive to establish efficacy and safety.

Material and Methods

The planned "Duphar" trial was an international multicenter, double-blind, prospectively randomized clinical trial aimed at comparing the antidepressant activity and safety of FLUVOX with that of imipramine (IMI) and placebo (PBO) in in- or outpatients aged over 18 years and suffering from a major depressive illness (according to the DSM-III definition).

Initially, there were 12 participating centers, 7 in North America and 5 in Europe (Table 1). FLUVOX and IMI, in unit doses of 50 mg, and PBO, in indistinguishable capsules, were administered according to a fixed-flexible dosage schedule: one capsule the first day, two capsules the second day, and three capsules from the third to the seventh day. After the first week the dosage could be adjusted, according to clinical judgment, from a minimum of one to a maximum of six capsules per day and administered, where possi-

[b] Patients with at least 14 days' medication and not dropped out after the 14th day because of possible study drug-related concurrent signs and symptoms or for reasons unrelated to study group.

[c] Outpatients.

[d] Inpatients.

[e] Study stopped after only a few patients enrolled; data not included in the analysis.

[f] Placebo-controlled study conducted under the same protocol; data not included in the analysis.

ble, three times a day. No other psychotropic medications were allowed with the exception of chloral hydrate or flurazepam, as hypnotics, only when this was unavoidable.

Patients with an established diagnosis of major depressive illness and with a score of at least 15 on the first 17 items of the Hamilton Rating Scale for Depression (HAM-D) at the end of the pretreatment period, and not precluded by the exclusion criteria (childbearing potential or pregnant women; antidepressant therapy in the past 2 weeks; electroconvulsive therapy within the last month; depressive symptoms secondary to other psychiatric illness; dependence upon licit or illicit drugs; serious organic diseases; need for concurrent medications which could interact with the study drugs or obscure their effects; and patients unwilling or unable to cooperate in the study) were included in the trial.

After a pretreatment period of 3 to 7 days, during which one capsule of PBO indistinguishable from the treatment capsules was given, patients received drugs for up to 28 days. For the North American centers, the treatment period was extended to 42 days. Analyses presented here are focused on 28-day data in order to utilize both European and North American data.

Assessment instruments were mostly the standard rating instruments of the BLIPS/BDP and the assessments were done on entry, at the last pretreatment day, and weekly thereafter (Table 2).

The main aim of this paper is to demonstrate the utility of the organizational model for this kind of study. Because of that, we will consider only the Adult Personal Data Inventory (APDI) for the demographic data, the Patient Termination Record (PTR) for the trial data, the HAM-D and the Clinical Global Impression Scale (CGI) for efficacy data, and the Dosage and Treatment Emergent Symptoms Scale (DOTES) and Treatment Write-in Scale (TWIS) for safety data.

Results

Of the 12 participating centers, only 8 furnished sufficient data for analyses (Table 2). Three centers (Nos. 3, 4, and 7) studied inpatients; all the others studied outpatients. Two North American centers (Nos. 8a and 8b) and one European center (No. 9) have been excluded from the analyses because of the small number of patients enrolled. Due to a delay in obtaining permission to conduct the trial

from the Italian authorities, the Pisa center (No. 10) conducted a separate PBO-controlled trial under the same protocol; the Pisa data are not included in these analyses.

Of the 481 enrolled patients, 448 had at least two evaluations during the drug intake period (Table 1) and have been included in the APDI, PTR, and DOTES analyses.

The distribution of the patients according to their major demographic characteristics (APDI)—age, sex, marital status, prior treatments, significant medical conditions, and previous hospitalizations—is approximately the same in the three treatment groups. The less-than-1-year duration of the actual episode is less (but not significantly so) in the PBO group (Table 3).

Data from the PTR (Table 4) provide significant differences among the three groups. The duration of treatment is approximately the same, but the reasons for premature termination differ significantly between active drugs and PBO. As can be expected, in the PBO group premature interruptions for ineffectiveness are relatively more frequent than in the two active drug groups, whereas the opposite is true for the adverse reactions. There were no differences among the groups in the number of patients requiring hypnotics, but a trend in suggesting mainly that patients on active drugs required more gastro-

intestinal preparation. To the question: "Given the choice, would you continue on this study medication?" the investigators' answer is significantly in favor of the two active drugs.

The mean daily dosage of the three treatments is similar in both the week-by-week analysis and in the overall treatment period. Maximum dosage is reached in the third week (Table 5). The most frequent side effect (rated at least moderate) observed in the FLUVOX group is "nausea." "Dry mouth," "sweating," and "dizziness" are more frequent in the IMI group (Table 6).

These preliminary findings allow us to discriminate between the two active compounds and PBO and, on the basis of side effects, to differentiate FLUVOX from IMI.

TABLE 5

At this point, rather than describe further the standard output of the BLIPS/BDP system, we would rather emphasize the flexibility and potential for rapidly and easily looking at the data in different ways. We will demonstrate the possibilities offered by the BLIPS/BDP system in handling and analyzing the pooled data of a large multicenter trial.

The major statistical procedure employed in the following analyses was a two-way analy-

[*] The Efficacy Index from the CGI combines a global rating of improvement and side effects.

sis of covariance ANCOVA where drug conditions and centers were the two factors in the design. For the efficacy data we performed two types of analyses "in parallel": the first includes all patients with at least two evaluations on drug (the so-called "intent-to-treat analysis"); the second method, which we call "efficacy analysis," is limited only to cases with at least 14 days' medication and not withdrawn after the 14th day because of possible study drug-related concurrent signs and symptoms, or for reasons unrelated to study drug (Table 1). With the BLIPS/BDP system, it is possible to perform the two types of analysis, one immediately after the other, by simply giving the computer the different selection criteria.

The score on the CGI item "severity of illness" is approximately the same in the three treatment groups (intermediate between "moderately" and "markedly ill") at the beginning of the treatment; the final score is close to "mildly ill" for FLUVOX and IMI and close to "moderately ill" for PBO in the intent-to-treat analysis. In the efficacy analysis, these differences are more marked and they reach the statistical significance in favor of the two active compounds (Table 7). Although significant differences were found between centers (Centers 2 and 3 in both analyses, Centers 3 and 6 in the efficacy analysis), no interactions between centers and drugs emerged.

For the CGI item "global improvement" the improvement is greater with FLUVOX and IMI than with PBO, but the statistical significance is reached only in the "efficacy analysis" where the FLUVOX- and IMI-treated patients are rated approximately "much improved" and the PBO-treated patients rated "minimally improved" (Table 8). The results of Center 2 are significantly different from all other centers except for Center 7, but no significant interactions between centers and drugs exist.

At the end of treatment, the number and percentage of patients judged as "much" or "very much improved" are greater in the FLUVOX and IMI groups than in the PBO group. These differences are greater (chi-square analysis) in the efficacy analysis (Table 9). The analysis of the CGI item "efficacy index" seems to favor FLUVOX over PBO and especially over IMI (Table 8).

TABLE 9

CGI — Global Improvement: Number and Percentage of Improved Patients

		Intent-to-Treat Analysis				Efficacy Analysis

or Worse	%	28.6	30.2	36.4	31.6	17.5	26.9	30.9	25.1
Total		161	149	143	453	120	119	123	362

The above examples give an idea of the utility of the BLIPS/BDP system in analyzing data derived from clinical trials of psychotherapeutic agents. However, the flexibility of this system enables us to perform many other analyses with very few additional simple external commands.

If, for instance, we want to study how the initial severity influences the results of treatment, we can stratify patients according to the initial severity on a selected assessment instrument and analyze the resulting groups as new cohorts. In this example, we used the initial HAM-D total score as an index of severity. In this study, 25.75 is the mean initial total score of the HAM-D and 5.72 the standard deviation (SD). We therefore consider "mildly" severe patients to be those with a score less than or equal to 20 (mean minus SD), "severe" patients with scores equal to or more than 31, and "moderately" severe patients with scores between 21 and 30. The ANCOVA (in this case drug conditions and level of severity are the two factors in the design) demonstrates that the pattern of improvement is almost the same for all analyzed items and factors (CGI and HAM-D). The improvement, however, is greater for the FLUVOX- and IMI-treated patients than for the PBO-treated patients. As is clearly seen in Table 10, the greater the initial severity, the greater is the improvement.

TABLE 10

Stratification by Initial Severity of HAM-D Total

*Adjusted scores.

**Covariance analysis: F>P - $p<0.05$
I>P - $p<0.05$

***Covariance analysis: Inpatients>Outpatients - $p<0.05$

As both inpatients and outpatients are included in this trial, one of the obvious analyses would be the comparison of results between the inpatients and the outpatients. With very few instructions, we stratified patients according to the treatment setting and again ran the two-way ANCOVA. The results demonstrate that the initial severity of the analyzed items and factors on CGI and HAM-D is higher in the inpatients than in the outpatients. This is shown in Table 11. For the HAM-D "retardation" factor, these differences are statistically significant.

Conclusions

In this paper, data from a multicenter international clinical study on FLUVOX have been presented to exemplify both the problems raised and the potential information that can be obtained using a comprehensive and standardized system of analyses.

The BLIPS/BDP standardized output provides a clear profile of FLUVOX from its efficacy to its safety through the comparison with IMI and PBO. Drug and center interactions, when present, are immediately in evidence, as well as possible limitations and inadequacies of the design or of the conduct of the study.

Once the cleaned data are stored in the computer data bank and processed, the first standard analyses can be presented to the principal investigators. This will stimulate suggestions for specific analyses. Multicenter trials, because of the number of subjects and centers, offer the possibility of a more complete study of a drug's profile as well as of the population in the study, and of the instruments employed in the ratings. In this way, there can be a complete exploration of the data which provides not only psychopharmacological information but also information on clinical, psychopathological, epidemiological, and transcultural aspects of the population under study. The BLIPS/BDP accomplishes this by a completely automated procedure, capable of answering a wide array of questions. Moreover, the standard outputs can be interpreted with great facility because they are in a uniform format.

Frequently, investigators collect data which are grossly underused in terms of the clinical information being analyzed. For this reason, we strongly recommend that multicenter clinical studies should be planned with a view to using an established proven data handling, processing, and documenting system.

In conclusion, we have shown that a multicenter international study can be successfully accomplished using customary pharmaceutical industry procedures and monitoring linked to an established standardized documentation system.

The Design and Conduct of the Upjohn Cross-National Collaborative Panic Study

Gerald L. Klerman, M.D.,[1] James H. Coleman,[2] and Robert P. Purpura, M.D.[3]

The decision by the Upjohn Company in the early 1980's to initiate a large and complex study came from two scientific developments: 1) new developments in understanding the psychopathology, diagnosis, and classification of anxiety disorders, and 2) the early experience with alprazolam, a new triazolobenzodiazepine.

New Developments in Psychopathology, Diagnosis, and Classification of Anxiety Disorders

The continuum model of anxiety (as shown in Figure 1) had been the dominant view of anxiety states for many decades. This model proposed a continuum from normal fears and tension through intermediate stages of stress reactions, to full-blown anxiety neurosis (whose most severe form was agoraphobia). From World War I through the 1970's, most clinicians, whether of biological, behavioral, or psychoanalytic persuasion, accepted this continuum model of anxiety. This model emphasized the gradients of severity and was built upon the experience of anxiety and fear in everyday situations and in adaptation, and evolution.

This model drew upon the psychological research of Cannon (1936) on "fight or flight" and his demonstration of the role played by the autonomic sympathetic nervous system. Later, biological research was extended by Selye to include the hypothalamic-pituitary-adrenal-cortical system as a mediator of "stress."

In the 1960's, a number of observers challenged this continuum view. Roth and associates (1960) in England described the "phobic-depersonalization syndrome," sometimes called the "calamity syndrome." West and Dally (1959) and Sargant (1960) described a group of atypical depressives with predominant anxiety symptoms who appeared responsive to monoamine oxidase inhibitors (MAOIs). In the United States, Klein and his associates (1964) described the failure of chlorpromazine to influence severe phobic anxiety and reported that imipramine, tricyclics, and antidepressants improved panic episodes and agoraphobia.

Further research demonstrated the value of two classes of antidepressant drugs: MAOIs and tricyclic antidepressants, in contrast to the limited efficacy of conventional benzodiazepines (Sheehan, et al., 1980).

As a result of these observations, the proposal was made (*see* Figure 2) to separate agoraphobia and panic disorder from other forms of anxiety disorders and to group these conditions together. These proposals were partially embodied in the Diagnostic and Statistical Manual—3rd ed., 1980 (DSM-III) classification of Anxiety Disorders, which represented a significant departure from previous U.S. classifications as in the DSM-I, DSM-II, ICD-8, and ICD-9.

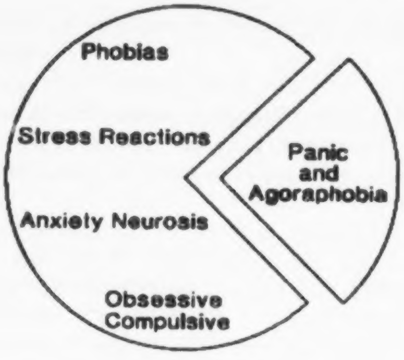

FIGURE 2. Panic and agoraphobia—separated.

In this new view, the central feature of the clinical psychopathology is the panic attack. The panic attack involves not just greater intensity of anticipatory anxiety, fears, and tension, but is a discrete time-limited episode with sudden onset of intense dread, accompanied by bodily symptoms suggestive of automonic arousal such as sweating, palpitations, tremor, and fear of losing control, going crazy, fainting, or dying.

There has been considerable controversy around the nosologic status of panic attacks, but also a continuing disagreement over the relative roles of drug treatment, MAOIs, tricyclics, beta-blocking agents, benzodiazepines, and also the efficacy and role of behavior therapy, particularly desensitization and exposure in vivo and flooding.

Alprazolam: A New Triazolobenzodiazepine

The chemical structure of alprazolam represents a modification of the conventional benzodiazepine ring structure by the addition of a triazolo group to the ring. The Upjohn Company developed a number of triazolo compounds, notably triazolam (Halcion) and alprazolam (Xanax). Trazadone (Desyrel), which has demonstrated antidepressant action, is also a triazolo compound.

Preliminary reports by Chouinard et al. (1982) suggest the value of alprazolam in panic disorder and agoraphobia, and these observations were confirmed in two controlled trials reported by Carr and Sheehan (1984).

The evidence presented by Ballenger at this meeting indicates the efficacy of alprazolam over placebo in the acute treatment of panic attacks and agoraphobia. Still unresolved is the question of the relative efficacy of alprazolam against other benzodiazepines, particularly diazepam. Experienced clinicians who have worked with patients with panic and agoraphobia are of the opinion that the efficacy of alprazolam is far superior to that of other benzodiazepines. Most patients entering recent trials with MAOIs, alprazolam, and tricyclics have had extensive prior treatment with benzodiazepines with limited success.

Should further studies demonstrate the superiority of alprazolam to other benzodiazepines, in what way can we account for this action of alprazolam? The efficacy of alprazolam in panic disorder could be due to pharmacokinetic or pharmacodynamic mechanisms.

There are suggestions that alprazolam has pharmacodynamic effects on the down-regulation of beta-blocking receptors. If substantiated, this pharmacologic profile of alprazolam would share certain similarities with antidepressant drugs such as tricyclics. Alprazolam has been effective in mild to moderate forms of depression, but not in severe endogenous, melancholic, or psychotic forms (Laakmann, in press).

The differences between alprazolam and other benzodiazepines may be pharmacokinetic. Assuming a ten-to-one equivalence between diazepam and alprazolam, 6 to 8 mg of alprazolam, the dose used in studies of panic disorder, would be the equivalent of 60 to 80 mg per day of diazepam, a dose which is seldom tolerated by most ambulatory patients.

Studies comparing alprazolam with diazepam at equivalent doses are underway and should help resolve this question.

Goals of the Upjohn Cross-National Panic Project

In 1982, the Upjohn Company initiated a worldwide panic program (Purpura, in press) which includes a number of interrelated pharmacologic, biologic, and clinical studies. Within the large program, the Cross-National Collaborative Panic Study focuses on clinical efficacy and safety.

The major goal of the Cross-National Panic Study is to assess the efficacy and safety of alprazolam in the treatment of panic disorder and agoraphobia. Subsidiary goals include: 1) better understanding of the psychopathology and diagnosis, and 2) improved means of diagnostic assessment and of evaluation of change in clinical trials of anxiety disorders.

Another subsidiary goal is to develop improved collaboration between industry, academic medical centers and universities, and governmental agencies in the U.S. and other countries.

To achieve these goals, the Cross-National Project is being conducted in two phases.

The *First Phase*, eight centers collaborating on the common design, which involves a comparison of alprazolam versus placebo, has been completed and results are being reported today. The eight centers are shown in Table 1 and include five in the U.S. (New York City, N.Y.; Iowa City, Iowa; Torrance, California; Rockville, Md.; and Charleston, S. Carolina), two in Canada (Montreal and Toronto), and one in Melbourne, Australia. Over 500 patients have been studied for an 8-week period in these eight centers. The dose schedule was a fixed, flexible dose with the attempt that all patients receive 6 mg per day of alprazolam, a dose considerably higher than previously used in studies of anxiety and depression. Diagnostic consistency is accomplished by the use of the Structured Clinical Interview for DSM-III Diagnosis (SCID), developed by Spitzer and Williams (unpublished).

In the *Second Phase*, alprazolam is being compared against placebo and against a standard drug, imipramine. The choice of imipramine as a standard drug was a difficult one, inasmuch as no drug treatment has been approved by the FDA for this condition. In the case of depressions, the tricyclic drug is the standard drug. In the case of beta-blocking agents for cardiovascular illness, propranolol is the standard drug. However, in the case of panic disorder and agoraphobia, no drug had been approved by the FDA, and there was no consensus in the field as to what should be the standard drug; conventional benzodiazepines, such as diazepam (Valium), a tricyclic, or an MAOI. Imipramine was chosen because of the extensive evidence for its efficacy (Liebowitz, in press).

This Second Phase of the study is now underway in 12 countries, and by the spring of 1986, approximately 1,000 patients will have been entered into treatment.

The First Phase and Second Phase studies utilize the same diagnostic criteria (modified from DSM-III), the same structured interview (SCID-up), and the same battery of scales and ratings for the assessment of clinical improvement and adverse effects. All data are encoded on upscan forms and sent to a central data processing facility in Kalamazoo, Michigan.

Assurance of Diagnostic Standardization and Quality Control

In any clinical trial, attention must be given to standardization of procedures for the selection of patients, randomization, assessment of change, control of concurrent medication, etc. In multicentered trials, particularly those which involve more than one nation, these considerations become all the more paramount. In addition, in this trial, since there was some degree of controversy over the validity of the diagnostic concept of panic disorder and its relationship to agoraphobia, considerable attention had to be given to the techniques to assure standardization of diagnostic assessment.

Among the techniques utilized, the following are noteworthy:

1) A very detailed protocol and procedures manual was prepared. The attempt was made to anticipate as many contingencies as possible, so as to provide explicit instructions to

the investigators, and to increase the likelihood that the study would be conducted in a similar way at all eight sites.

2) To ensure diagnostic consistency, a modification of the DSM-III criteria for panic attack, panic disorder, and agoraphobia were developed as part of an ongoing consensus project among the investigators at the eight sites, and involve a large group of consultants who have been active in the field.

3) A structured interview, the SCID-up, was commissioned for the explicit purpose of standardizing the interview procedure, so as to reduce information variance and criterion variance. Drs. Spitzer and Williams at the New York State Psychiatric Institute and Columbia University, College of Physicians and Surgeons, developed the SCID-up to operationalize the criteria for the study, including inclusion and exclusion criteria. The SCID-up has been translated into a number of languages for the participating countries in phase two, and extensive training and reliability exercises have been conducted.

4) A 1-week training workshop was held in Boston in 1983 for the first-phase investigators, and in Pisa, Italy, in November of 1983 for the second-phase investigators. During this training exercise, the protocol was reviewed in great detail, the concept and criteria for panic attack and agoraphobia were discussed extensively, video tapes were viewed, the SCID-up was explained, and experience was gained in the use of the SCID-up in interviews with patients from local clinical settings.

5) Special attention was given to provide operational definition and systematic assessment of panic attacks. Since the reduction of panic attacks was the major outcome of the study, it was necessary to devise a new instrument. Based upon Dr. Sheehan's previous experience, with assistance from consultants (particularly Drs. Spitzer and Williams), a detailed assessment of panic attack was devised which incorporated distinctions between spontaneous and unexpected panic attacks and situationally provoked panic attacks and limited symptom attacks, and these were further distinguished from anticipatory anxiety. In addition to the physician-guided ratings, each patient completed a weekly log in which daily records were kept of the number, intensity, and duration of attacks, medication taken, and activities outside of the home.

6) As a further assurance of systematic standardization in quality, a quality assurance program was instituted in which teams of two consultants not directly involved in any of the clinical sites were recruited and trained and then made on-site visits to each of the sites at least twice during the conduct of the trial. During these visits, the records were reviewed for diagnostic consistency, and interviews with patients were observed and assessed.

Organization of the Study

The overall project, including the two phases, is coordinated by Mr. Coleman and Dr. Purpura of the Upjohn Company. I serve as a consultant.

In addition, there is a *Study Review Committee* chaired by Dr. Daniel X. Freedman which operates similarly to operations committees in VA cooperative studies, namely, it is unblinded and periodically reviews the progress of the study and evidence as to indices of safety and efficacy, in order to terminate a study for ethical reasons either because of the adverse effects which pose risks to the patient or the evidence of overwhelming efficacy which would lead to compromising the needs of patients exposed to placebo. This group also advises informally on matters of research design, statistics, and interpretation of findings.

For each two phases of the study, a *steering committee* composed of the senior investigators and co-chaired by Mr. Coleman and Dr. Klerman meets periodically to review decisions and protocol, to plan data analyses, and to monitor progress. In addition to the meetings two or three times a year, monthly teleconference calls provide for ongoing discussion of issues in the conduct of the trial, management of possible complications, and to ensure data processing and data analysis.

Training sessions have been held for each phase. The phase-one investigators met in Boston, Massachusetts in February 1983, for 1 week to review the protocol and to obtain training and experience in the use of a structured interview, the SCID.

Similar training sessions for the second phase of investigators were held in Pisa, Italy, in November 1983.

Data Processing and Data Analysis

This study has generated considerable amounts of data. Data processing is facilitated by the use of upscan forms for primary entry of data. Manual editing is conducted by the Upjohn Company and the data is entered into a computer in Kalamazoo, Michigan. Once the data processing has been completed and an edited tape is prepared, analyses are conducted at two sites — Kalamazoo, Michigan, and Massachusetts General Hospital, Boston, Massachusetts. The primary responsibility of the group at the Upjohn Company in Kalamazoo is the conduct of analyses to ensure proper information for the NDA submission to the FDA for the expected indication of treatment of panic attacks. Analyses primarily for scientific value for research undertaken by the investigators is conducted at the Massachusetts General Hospital under the leadership of Philip Lavori, Ph.D., and myself. Decisions as to scientific publications are made by the principal investigators at their respective steering committees. The Upjohn Company does not assume responsibility for scientific presentation or publication, although it has underwritten a considerable amount of the cost required for statistical analyses, preparation of graphic material, and secretarial assistance.

Conclusions

The findings to be reported here indicate the success of the overall design and the procedures utilized to ensure standardization of diagnosis and maintenance of the protocol across multiple sites in three different countries. It is expected that these procedures and techniques will prove useful in the second-phase study. Inasmuch as the second-phase study involves at least 12 different countries with multiple languages, cultural, and professional traditions, the attention given to diagnostic specification and careful assessment should prove helpful.

Preliminary experience indicates that over the course of the 2 1/2 years since this project was initiated, there have been greater acceptance and diffusion of the concept of panic attacks and panic disorder in relation to agoraphobia, and that participants in this study have increasingly accepted these diagnostic concepts as well as the importance of structured interviews and diagnostic algorithms for the selection of subjects, particularly in an area where there is controversy as to the validity of the diagnostic concept.

A clinical trial such as this one can serve as a partial validation of diagnostic concepts, in this case, panic disorder. The capacity to generate large numbers of cases in multiple sites and to demonstrate consistency of diagnosis and similarity of symptom pattern and of treatment response serves as an indirect validation of the concept of separating panic attacks from other forms of anxiety and linking panic attacks with agoraphobia as a diagnostic complex.

Why a Statistical Package on a Micro?

MaryAnn Hill, Ph.D.[1]

The explosion in microcomputer sales promises to alter our society in fundamental way, changing the way we work, plan, and organize our lives. But without effective software, the microcomputer remains an engaging toy. Many researchers are currently evaluating the role of the micro in their research environment and are asking, "What kind of statistical software do we need?", "Will we have to give up familiar mainframe options?", etc.

There are several advantages in using a microcomputer to do the statistical analysis in research. Locating a micro close to the research team and its original data sheets facilitates data screening and also communication between the technical support staff and the research team. The technical support staff find it easier to focus on the data analysis, because on a micro the interface with the system is more "user-friendly"—allocation and naming of files is greatly simplified and there is no mainframe job control language (JCL). Even if the project is part of a large multicenter trial, much of the data monitoring and screening can be done on the micro and the clean data shipped or networked to the mainframe for final analyses with data from all centers. Finally, most project managers are happy to reduce mainframe computer bills.

Regardless of machine size, it pays to use a statistical package. Advantages include:

- *Correct computations.* The well-known packages have been "debugged" over a broad range of applications, and they use appropriate algorithms—they do *not* simply code textbook formulas.
- *More time for research,* because less time is spent programming.
- It is easier to do *"good" data analysis* because many data screening features appear automatically—e.g., histograms for each group in a two-sample t test.
- *One-time specification of data description instructions.* Variable names, formats, acceptable range limits, flags for missing data, transformations, etc. do not need to be tailored for each individual analysis.
- *Documentation and help facilities.* The major package distributors provide extensive manuals, short courses in data analysis, and help via telephone. You are not stuck because your programmer disappears to Tahiti.

— The use of packaged software *facilitates communication of results* when submitting grant proposals and papers to refereed journals, since the methods are well known and documented.

Unfortunately, much of the statistical software for the micro is woefully inadequate. A data analyst needs a wide spectrum of techniques that can be applied easily to a collection of data. If I were called in to consult with your research team, I would need access to a number of features, all of which are currently available on an IBM PC XT or AT (and compatibles). I do not intend to present a detailed explanation of the statistics, but hope to impart a flavor of the breadth of supports required for proper data analysis. From these examples, I hope that you will understand my concern when a research group shows me preliminary results consisting of nothing but means, standard deviations, *F* statistics, and *p* values.

In addition to statistical supports for data analysis, packages often have data manipulation features that merge files and functions that extract information from nonrectangular files. Without such features on a micro, a longitudinal study would be seriously hampered.

Software Features for Data Analysis

Many of the features I would hope to find on your micro are needed for data screening. The term "screening" indicates not only finding errors and inconsistencies in the data, but also ensuring that the data conform to assumptions necessary for subsequent analyses. Screening is not one set of procedures carried out prior to the analysis—each stage of the data analysis uncovers information that affects later steps. In sizable studies, the primary analysis of interest may consume 5% of the staff time and computer costs, while data screening takes 95%. The data analyst will want to check for recording errors and compliance to protocol, as well as assess the influ-

ence of outliers, distributional shape, subpopulations, patterns of missing observations, etc. Having a good statistical package at the research site makes it possible to check the data soon after they are captured—while it may still be possible to make corrections.

Testing group differences

The data analyst needs graphical displays, diagnostics, and alternative tests to help estimate the impact of problems encountered. In comparing responses for a treatment group and a control group, recording errors and other anomalies pop out when you scan small histograms for each group (high resolution graphics are not needed). In Figure 1, case 24, a control subject has a very high response. Does this real, but unusual response change our conclusions about group differences? Compare the results for the usual two-sample *t* test with those for the trimmed *t* test (note the trimmed test does not simply delete the smallest and largest values from each group—an adjustment is made to the standard deviations used in the denominator of the test statistic). Here both tests are significant.

The data analyst wants to study the distribution of values within each cell: scanning a printout of means and standard deviations may be far from adequate. In a recent project, one criterion for study entry was a Hamilton depression score of 18 or above. In a screening run of baseline scores, by doctor, (*see* Figure 2), 6 subjects appear unacceptable for study entry. This was distressing since the admitting psychiatrists had just spent weeks being trained on the anchor points for each individual scale item. So why did one doctor's rating differ? From a quick telephone call we learned that he made his evaluation using the previous 12 hours instead of the patient's history for the past week. Seeing a printout of means would not have had the same impact (the mean for doctor B was over 19).

As structure is added to the design—e.g., we study differences between treated and untreated subjects who are males and females, smokers and nonsmokers, etc.—the data analyst still wants to scan distributions within each cell for outliers and other anomalies. He also needs tests to assess the equality of cell variances, diagnostics to identify the appropriate power transformation, and extensions for the two-sample trimmed *t* test to analysis of variance (ANOVA). In an ANOVA, there should be no relation between the size of the cell standard deviation and the size of the cell mean—i.e., the cell variances should be equal. From information printed with the BOX-COX diagnostic plot (Figure 3), the data analyst would determine that the equal variance assumption is best satisfied if the data are analyzed in log units.

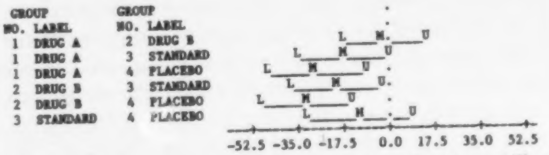

FIGURE 4. **95% confidence intervals for differences in group means with Bonferroni adjustment (means differ significantly when 0.0 is not in the interval).**

If an effect in an ANOVA is significant, the analysis is still not complete—the researcher wants to report which group means differ from one another. Probabilities from the usual two-sample *t* test cannot be used to find significant differences (since this test assumes that only one pair of means is compared). When many comparisons are made

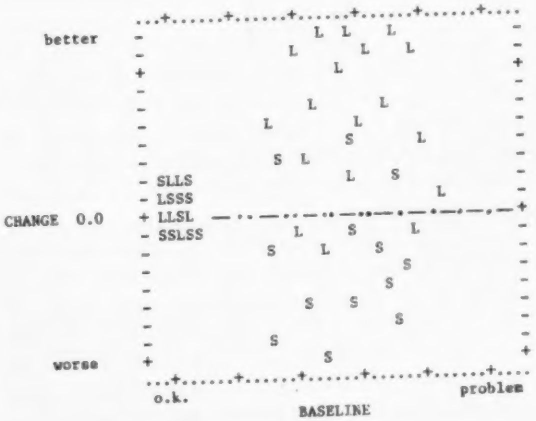

FIGURE 5. **A bivariate scatterplot with symbols S and L denoting subjects on DRUG S and DRUG L, respectively, highlights the fact that the CHANGE in cardiovascular status after drug therapy becomes worse for a small subset of DRUG S patients; while several DRUG L patients improved.**

simultaneously, the Bonferroni procedure can be used to protect against interpreting too many differences as significant. In Figure 4, confidence intervals (with Bonferroni adjustments) are displayed for differences among four means (DRUG A, DRUG B, STANDARD drug, and PLACEBO)—there is one line in the display for each pair. If zero is not in the interval (draw a vertical line down through the dots to 0.0), the pair has a significant difference in means. The difference between DRUG A and the STANDARD drug is questionable—the upper end of the confidence interval (U) touches the zero line, while the differences between both DRUG A and DRUG B versus PLACEBO are highly significant.

Relating two or more variables

When studying the relation among two or more variables, linear models (e.g., regression models and analyses based on correlations) may not be enough. By scanning a printout of correlations and regression coefficients, the researcher may not be able to see that a small subset of the subjects responds differently from the others. Bivariate scatterplots are useful in such situations, especially when symbols are used to identify subpopulations. In Figure 5, CHANGE in cardiovascular status after drug treatment is plotted against baseline values. Holter monitors were used to obtain the measurements. The majority of the subjects (more than 85% of the sample) exhibited no problems at baseline and no change after being on a drug. However, among those subjects with problems on baseline, several DRUG L subjects improved, while the status of several DRUG S subjects became worse.

Labeling subpopulations in scatterplots is also useful for identifying situations where the presence of subpopulations may mask or falsely enhance the relation between two measures. Two pairs of measures from the Fisher Iris data (Fisher) illustrate this point well. Pooling data for three types of iris flowers into one sample in Figure 6a, masks the relationship between sepal length and width—there is no relationship or at most a slight *negative* correlation. The points labeled "S" in the lower right are Setosa flowers—note how the relation for them appears to be *positive* (for the Setosa flowers alone, the correlation is +.74). In Figure 6b, when data are pooled for a plot of petal length versus width the correlation is .96; for Setosa alone, the correlation drops to .33.

When studying the intercorrelations of many variables—e.g., in the development of a questionnaire or a rating instrument—it is helpful to use a factor analysis to sort the rows and columns of a correlation matrix into blocks of similar values, and then to use a single character space to represent each correlation (*see* Figure 7, for a shaded correlation matrix for a 43-item questionnaire about smoking habits and emotional stress). The 13 smoking items appear highly intercorrelated, with the possible exception of the last item in the list, SMOKING 3. The question about

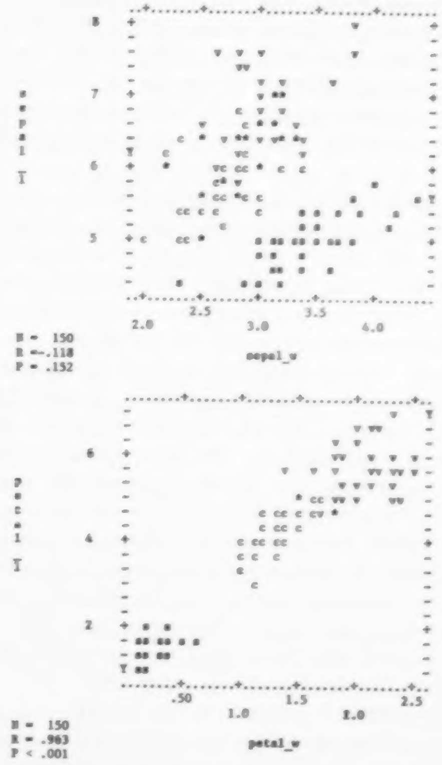

FIGURE 6. a) The presence of subpopulations can mask a relationship: sepal length versus sepal width. b) For petal length and width, the presence of subpopulations gives a false impression of the strength of the relationship.

hunger (HUNGRY—the third up from the bottom of the display) appears to have little relation to any of the other items.

When there are only two variables of interest, much can be gleaned from studying a scatterplot. However, as the number of variables in a multivariate analysis increases, additional diagnostics are needed to identify outliers and cases that exert unusual influence on the analysis. In the plot of Andrews-Pregibon statistics in Figure 8, unusual values of the statistic plotted on the AP1 axis indicate outliers in the dependent variable. One value at the top right stands apart from the others and should be checked. Unusual values on the AP2 axis are "leverage" points—cases that exert the greatest influence on the regression coefficients. Here two cases are separated from the others and identified as

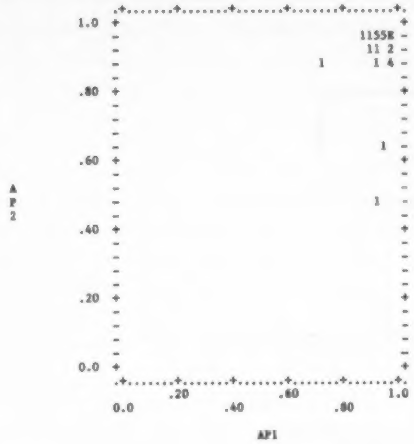

FIGURE 8. Andrews-Pregibon diagnostics AP1 and AP2 for identifying outliers and leverage points in multiple regression.

unusual. The case numbers for the three cases identified are printed in the output.

Studying the pattern of incomplete data

Missing data are often a nightmare for the data analyst. Procedures for dealing with incomplete data usually assume that values are missing randomly. The pattern of how values are missing should be investigated, since nonrandomly incomplete data can bias results. One of the first things the data analyst does when searching for patterns is to print a display of the data with one character per variable: a blank if an observation is present; a letter "M" if missing. In Figure 9, the LAB chemistry measures tend to be missing as a set. In Figure 10, a multiway table is used for deciding if this pattern is related to the outcome, SURVIVAL. Over two-thirds of the survivors (68.5%) are missing all three lab values, while fewer than 10% of the non-survivors have data missing.

Software Features for Managing the Data

Data in longitudinal studies often fail to conform to the nice tidy rectangle required for analyses based on classical statistics. Patients may have varying numbers of visits and different patterns of return across time. For example, it may be necessary to extract from a series of records the number of visits, total time on study, percent improvement for the clinical rating score, worst side effect score, drug dose for week prior to worst score, etc., for each patient. For analysis, the summary of the patient's clinical experience will need to be merged with laboratory results and patient history data.

The entry of patients into the study may be staggered over time, making it hard to visualize the pattern of return visits and the total time on study for members within each treatment group. In order to plan analyses, the data analyst needs this information. In Figure 11, a record map is displayed for a study where patients are asked to return weekly for evaluation (one computer record is generated for each return visit). Week-on-study is recorded on the horizontal axis, and each row represents the pattern of returns for a single patient over time. The drug code is used as a

```

plot symbol; blanks mark missed visits. Subject 19 (*see* underlined row) was randomly assigned to drug 1 (the plot character is 1) and continued on it for 17 weeks; had 2 weeks of wash-out (code 4); and then was randomized to drug 2. It is immediately apparent that, as time on study increases, many patients drop out and the frequency of returns decreases.

With such a distribution of values across time it is hard to use a classic repeated measures design to test for differences among the drug groups. Instead, our strategy might be to extract information from each patient's set of records (the number of records varies by patient). This summary information would then form a rectangular file and be available for plots, histograms, analysis of variance, logistic regression, etc. The data for each patient might include clinical ratings (at baseline, 4 weeks, 8 weeks, and so on.), proportion of visits with side effects present, maximum dose, drug dose for week prior to worst side effects score, and within-subject correlation between dose and side effects.

Conclusion

A microcomputer can be an effective tool for data analysis, but only if adequate software is available. A statistical package for a micro must go far beyond the simple computations of commonly used statistics. Indeed, it must encompass most of the power of the standard mainframe packages.

Microcomputerized Testing of Drug Effects on Divided Attention[1]

Joe E. Thornton, M.D.,[2] Joy L. Taylor, Ph.D.,[2] Elizabeth L. Gibson, M.A.,[2] Terry P. Miller, M.D.,[2] and Jared R. Tinklenberg, M.D.[2]

In this paper we describe the use of a microcomputerized, dual-task methodology to test drug effects on divided attention. This dual-task methodology is designed to be sensitive to psychoactive drugs and to be useful in research that entails repeated assessments of the same individual. The theoretical rationale for this approach is that drug effects may be especially discernible on pervasive, non-specific processes such as attention and may be most amenable to quantification on performance tasks that are attention demanding. Certain additional psychometric and technical features of these microcomputerized tasks which make them suitable for psychopharmacologic studies will also be discussed.

Methods

The essential feature of the dual-task method is that the subject must perform two activities simultaneously. In one version of this method, which is described below, the subject also performs each task individually to provide comparisons for the dual-task condition. The decrement in performance observed when the two tasks are done simultaneously, relative to the performance observed when they are done separately, provides a measure of the extent to which the available attentional capacity is exceeded.

In our basic dual-task procedure, the first task involves manipulating an x-y joystick to pursuit track a randomly moving target, which is displayed on a video screen. The subject manipulates this control stick up/right and left/right with the preferred hand. The target is a 1.5 cm horizontal line and the joystick position is displayed as a 1.5 cm vertical cursor line. The task is to maintain a "crosshair" configuration by keeping the middle of the vertical cursor line as close as possible to the middle of the randomly moving horizontal target line. The target moves at a maximal rate of about 6.6 cm/sec throughout an unmarked 12 × 18 cm rectangle, positioned at the center of a standard 42 cm diagonal video screen. The screen is approximately 50 cm from the subject's eyes.

The second task involves the continuous monitoring of visual probe stimuli embedded in the horizontal tracking target line. The stimuli are a pair of boxes, about 4 mm long × 5 mm high, at each end of the target line. They both blink in synchrony at a baseline rate of about 1 blink/sec. The subject presses the reaction button, which is held in the non-preferred hand, as soon as he or she notices an increase in blink frequency of the boxes (to 1.8 blinks/sec). This change occurs at quasi-random intervals, approximately 4 times per minute. The button press restores the blink frequency to baseline. The temporal perceptions required in this task and the relatively high rate at which the visual stimuli must be processed combine to enhance drug sensitivity. Both tasks are designed to be intrinsically uninteresting and subtle in their measurement of performance changes. Most subjects perceive these tasks as undemanding commercial videogames, which are meant to arouse and stimulate.

The basic procedure involves three test conditions: a) a single-task only is performed, the other is ignored; b) the other single-task only is performed, the first is ignored; and c) then both tasks are performed concurrently. In the dual-task condition the subjects are

instructed to do the tracking task as well as possible and do the visual probe monitoring with whatever abilities remain. In experiments where we focus on attentional capacity, each task condition lasts 5 minutes. The order of tasks is first tracking only, then reaction task only, and then both tasks simultaneously (dual-task). Any decrement in the dual-task condition relative to the single task conditions indicates the extent to which the available attentional capacity is exceeded. In experiments where we are most interested in drug effects on general performance, we use only the dual-task condition and measure time-on-task changes during 15 or 20 minutes of continuous performance. Continuous performance obviates the confounding effects of any task interruption. The subjects receive no feedback about their performance in either paradigm.

We use Apple II and Apple IIe hardware with programming done in UCSD-Pascal. The tasks are run on an Apple II (or IIe) microcomputer using the UCSD Pascal Operating System. It requires a) an x-y joystick; b) a California Computer Systems programmable timer module (PTM) card, appropriately modified, in slot seven of the Apple II; c) a press button switch connected to the PTM; and d) dual floppy disk drives for data storage. The software for the pursuit tracking and visual monitoring procedure (PTRAK), described above, is written in UCSD Pascal and 6502 machine code. The Pascal portion of PTRAK controls the presentation of the secondary visual probe and records performance; the 6502 routine draws the positions of the target and cursor. Every 75 msec tracking accuracy is measured as the radial distance in pixels between target and control stick cursor. A pixel in this system is about a 1.0 mm horizontal and 0.6 mm vertical dot. Reaction time to the probe (to 1 msec accuracy) or a "miss" (i.e., no response within 1500 msec) are recorded. Additional technical and theoretical considerations are described elsewhere (Tinklenberg & Taylor, 1984; Tinklenberg et al., 1984, 1985).

Results

In repeated measures research designs such as those usually used in clinical psychopharmacology, an essential requirement for any performance assessment procedure is adequate test-retest reliability. We determined the test-retest reliability of PTRAK on five normal volunteers in the basic divided attention paradigm. When testing was done 1 day apart the Pearson correlation coefficients were greater than 0.80 on both tracking and reaction time performance. Testing after 1 week, the Pearson coefficients were greater than 0.69 for both tasks. One subject was tested 20 times over a 6-month period. Examination of his performance indicates an immediate improvement or practice effect in the 5-minute paradigms if testing is done on the same day or on consecutive days. This practice effect is not evident if testing sessions are more than a week apart. When the subject was tested for 10 consecutive days, performance stabilized by the fifth testing day. In the 20-minute time-on-task paradigm, practice effects are less evident.

Another obvious requirement for any psychopharmacological assessment procedure is appropriate drug sensitivity. Initial studies with dual-task procedures are promising. In a single-blind study with normal subjects, single doses of diphenhydramine 50 mg orally significantly impaired performance; 100 mg of caffeine 3 hours after diphenhydramine ingestion restored most of the performance deficit. When diphenhydramine followed caffeine, performance did not improve. We have also shown PTRAK to be sensitive to drug effects in abstinent alcoholics (Miller et al., in press). There was consistent impairment of dual-task performance with diphenhydramine: 50 mg, diazepam: 10 mg and 20 mg, and secobarbital: 100 mg.

Discussion

These preliminary results suggest to us that microcomputerized dual-tasks have adequate reliability and drug sensitivity for use in research. They also have many practical advantages in psychopharmacological studies relative to traditional tasks. Patient acceptance is generally good, and they often enjoy the game-like quality of the task. Since specific feedback is not given and level of performance is not apparent, performance anxiety is minimized. Also, the equipment is portable, relatively inexpensive, and can be adapted to obtain concurrent physiological measures of arousal such as heart rate. Personnel requirements are minimal. A tester requires little training and once the task instructions are given to the subject, the tester does not have to be present. The testing conditions are standardized and exactly replicable, even among different research groups. This is especially important with the repeated measures designs often required in testing for effects of drugs on cognitive performance.

There are also psychometric characteristics of these dual-task procedures that make them attractive for pharmacological studies. A common problem in psychopharmacology is the wide range in the performance abilities of patients. Tests that are too easy for some subjects are too difficult for others. With dual tasks these "ceiling" and "floor" restrictions are circumvented to some degree. The tracking task can be performed at widely varying levels of proficiency—ranging from continuous close contact with the target to distances on the order of 4 to 5 cm—and still be statistically and psychometrically meaningful. This feature of the tracking task is in contrast to our experience with, for example, verbal learning tasks. A second psychometric advantage is the tests' suitability for repeated assessments. Unlike some standard intelligence and memory tests, which have only a single form of the test, each session of this computerized performance test consists of randomized presentation of stimuli.

There are more potential advantages with microcomputerized dual tasks. Adaptive logic can be used so that task difficulty varies during a single test session, e.g., the performance of subjects with different abilities can be kept within specified error limits. The priority assigned to each task can be systematically manipulated so additional inferences can be made about attentional capacitites and control. Dual-task results can be interpreted on the basis of extensive theoretical and experimental work in human factors research.

There are some problems with the microcomputerized testing. Our experience indicates the need for experimental designs which can control for practice effects and performance variability due to factors such as time of day, smoking, diet, exercise, emotional state, etc. Also, some subjects change performance strategies, so that testers occasionally have to monitor the subjects performance throughout a session. With the procedure described above there is a lack of face validity, i.e., a more meaningful task might require the same perceptual and motor skills but use a graphics and hardware system that resembles an automobile. But even at this simple level the technical demands of initial development and modification are formidable and require professional engineers and computer programmers.

In summary, we believe the special psychometric characteristics and sensitivity to experimental interventions make microcomputerized dual tasks a potentially important tool in clinical psychopharmacology.

The Use of Benzodiazepines for Psychotic Disorders: A Literature Review and Preliminary Clinical Findings[1]

George W. Arana, M.D.,[2] Marjorie L. Ornsteen,[2] Fred Kanter, M.D.,[2] H. L. Friedman, M.D.,[2] David J. Greenblatt, M.D.,[2] and Richard I. Shader, M.D.[2]

Introduction

Although antipsychotic agents (neuroleptics) have been shown to be effective for the treatment of various psychotic disorders including schizophrenia and the affective psychoses, limiting factors such as latency for onset of action (10 to 14 days) and short- (acute dystonias, neuroleptic malignant syndrome), medium- (parkinsonism, akathisia), and long-term side effects (tardive dyskinesia [TD]) have necessitated the search for other compounds that may be effective for psychotic symptoms (Baldessarini, 1980). Recent findings suggest that certain subgroups of psychotic patients may be at increased risk for TD depending on age, diagnosis, and duration of treatment (Mukherjee et al., 1982; Toenniessen et al., 1985), although much controversy still exists about these associations (Kane & Smith, 1982). Benzodiazepines, because of their low toxicity, have been studied both as potential non-neuroleptic antipsychotic agents and as adjunctive treatments for psychotic disorders, to increase sedation and possibly to allow for a significant reduction of neuroleptic dose.

We will review briefly the available literature on the use of benzodiazepines for psychotic disorders, present data from a retrospective chart review on the utility of combined use of neuroleptics and lorazepam, and review preliminary findings of an ongoing study assessing the use of lorazepam alone and lorazepam combined with haloperidol in two groups of psychotic inpatients.

In the literature review we included only those publications containing the actual number of patients responding to a specific regimen. This allowed us to construct efficacy and toxicity data about those who either responded or developed toxicity as a function of the total number treated across studies. Because the efficacy criteria were not uniform among the individual publications, it was not possible to clearly specify whether improvement was in core psychotic symptoms or in such associated symptoms as anxiety and agitation.

Efficacy of Benzodiazepines for Psychotic Illnesses

Diazepam

Although a variety of benzodiazepines have been employed in the treatment of psychotic disorders, diazepam is the most frequently studied compound. Table 1 presents the selected literature on the use of diazepam for schizophrenic disorders (Beckman & Haas, 1980; Hollister et al., 1963; Jimerson et al., 1982; Jos et al., 1985; Maculans, 1964; Nestoros et al., 1982, 1983; Ruskin et al., 1979; Weizman et al., 1984).

Early uncontrolled studies using relatively lower doses of diazepam were conflicting, some reporting dramatic reductions in hallucinations mand delusions in schizophrenics (Irvine & Schaechter, 1969; Kramer, 1967; Sussex et al., 1961) and others reporting that diazepam had little effect. As is evident from Table 1, few patients were studied in well-controlled clinical trials with fixed-dose regimens.

When double-blind trials are assessed separately, only 14 of 47 subjects (29%) were found to have responded, an efficacy rate equal to what is generally regarded as placebo response rate. Factors which could contribute to response rate such as clinical presentation, response to other medications, or the utility of combined therapies are inconsistent when reviewing this literature. One double-blind study described the use of diazepam for schizophrenic patients who previously were poor neuroleptic responders (Maculans, 1964); another reported a response rate to diazepam comparable to the neuroleptic response rate (Jimerson et al., 1982). Two groups, in double-blind crossover studies using diazepam, found no antipsychotic effect as compared with placebo in doses from 40 to 80 mg/day in one (Ruskin et al., 1979) and 300 mg/day in the other (Jimerson et al., 1982). In contrast to these negative findings, another group reported a dramatic reduction in both positive and negative psychotic symptoms, a broad range of diazepam doses were employed (70 to 400 mg/day) (Nestoros et al., 1982). Finally, in a double-blind randomized trial of haloperidol and diazepam (not shown in Table 2), both compounds were equally effective for the treatment of psychotic symptoms in the first 24 hours, with a trend in favor of diazepam in the first 4 hours (Lerner et al., 1979). The authors speculate that some components of psychosis may be secondary to arousal or anxiety, thus leading to the apparent efficacy of a benzodiazepine compound for psychotic symptoms (Lerner et al., 1979).

#(Patients with antipsychotic response)/(Total patients studied).

**Patients concomitantly treated with haloperidol, 15 mg/day.

When all cases (double-blind and others; Table 1) are totalled, response rate is 34% (42/120). The studies reporting the use of diazepam at doses below 40 mg ($N = 60$; 51%) yielded a response rate of 28% (17/60); the three reports using over 100 mg of diazepam had an overall response rate of 33% (11/34). There does not appear to be a dose-related response pattern for diazepam in psychotic illnesses. An overall response rate of approximately 30% emerges regardless of dose used or the design of the studies.

In addition to diazepam, other benzodiazepines have been used for the treatment of psychosis (*see* Table 2). Although these reports are brief and preliminary, they offer some data on the efficacy of this class of drugs for psychotic and bipolar disorders (Astrup & Vatten, 1984; Chouinard et al., 1983; Csernansky et al., 1984; Deberdt et al., 1973; Freinhar & Alvarez, 1985; Guz et al., 1972; Hekimian & Friedhoff, 1967; Holden et al., 1968; Karson et al., 1982; Kellner et al., 1975; Lingjaerde, 1982; Modell et al., 1985; Monroe & Wise, 1965; Victor et al., 1984).

Clonazepam

Recently, interest has developed in the use of clonazepam, a benzodiazepine usually employed for its anticonvulsant properties (Browne, 1976). A number of papers have appeared exploring its value for the treatment of psychotic illnesses, particularly mania (*see* Table 2). Unlike neuroleptics, there is little risk of extrapyramidal or anticholinergic side effects, although drowsiness and ataxia, apparently dose-related symptoms occurring early in treatment, appear to be problematic (Browne, 1976).

Few controlled clinical trials of clonazepam have been conducted to assess its efficacy in the treatment of mania and psychosis. In a double-blind crossover study of 12 acutely manic patients, one group has reported that clonazepam was as effective as lithium for manic symptoms and superior to lithium for motor activity and logarrhea (excessive speech) (Chouinard et al., 1983). Two reports describing 5 patients found that clonazepam ameliorated anxiety and agitation and a limited number of manic symptoms, but psychotic symptoms (delusions, hallucinations) were refractory (Freinhar & Alvarez, 1985; Victor et al., 1984). Two reports suggest that clonazepam may precipitate aggressiveness and irritability (Browne, 1976; Karson et al., 1982). One group, in a double-blind study of 9 schizophrenic patients concomitantly treated with neuroleptics, found clonazepam to be ineffective for target symptoms of psychosis. In addition, 4 patients developed aggressive, violent outbursts, 3 of whom had no prior history of violence. The assaultive episodes occurred when the dose was being adjusted (Karson et al., 1982). These investigators concluded that clonazepam was not effective in the treatment of exacerbations of psychosis in chronic schizophrenics receiving neuro-

leptics, and that it had the potential for inducing aggressive behavior. Finally, another report has indicated that psychotic symptoms, including irritability and aggression, may worsen in adolescents treated with clonazepam (Browne, 1976).

Lorazepam

Lorazepam is well established in psychiatry as an anxiolytic. Its efficacy in psychotic disorders is less well studied and confounded by secondary anxiety and arousal that may coexist in many psychotic patients. One investigator suggests that lorazepam is an effective adjuvant for the anxiety which accompanies psychosis but has no effect on the target symptoms of psychosis (Deberdt, 1973). A recent open clinical trial found lorazepam effective in the control of manic agitation and in promoting compliance and cooperation during the institution of lithium therapy, concluding that manic as well as other psychotic symptoms resolved within 10 days when both lithium and lorazepam were used (Modell et al., 1985). However, the course of recovery from the manic episode left it unclear as to which drug was more effective (Modell et al., 1985).

Estazolam

The effects of estazolam, a benzodiazepine not currently marketed in the United States, have been tested in psychotic illnesses. In a double-blind study of estazolam in 58 chronic schizophrenics, it was found that estazolam in combination with a neuroleptic was better than neuroleptic alone for the treatment of hallucinations and compulsive thoughts as evident in global clinical improvement (Lingjaerde, 1982). Another group reported the use of 4 to 6 mg of estazolam in an open trial for 53 chronic schizophrenics, concluding that this drug decreased delusional and paranoid symptoms in 15/53 patients (Astrup & Vatten, 1984). In both studies, patients were characterized as poor neuroleptic responders and were maintained on neuroleptics during the treatment with estazolam. Although encouraging, further placebo-controlled studies are needed to assess the specific efficacy of estazolam in these patients.

Alprazolam

In an open trial of alprazolam evaluating its therapeutic effect on the negative symptoms in 8 chronic schizophrenics, partial reversal of negative symptoms was observed in 6 patients, and an anxiolytic effect in all 8 (Csernansky et al., 1984). Conclusions that can be drawn from this particular study are limited, as all patients were concomitantly treated with neuroleptics. Fifty percent of the patients had a moderate overall clinical response to alprazolam. Because alprazolam is known to be effective for anxiety, panic, and depressive disorders, this improvement may have been secondary to other possible effects of this drug.

Chlordiazepoxide

Seven reports on the use of chlordiazepoxide reveal generally inconsistent findings on its efficacy in psychosis. In particular, the question of increased efficacy for psychosis if both chlordiazepoxide and neuroleptics are employed is unanswered. Three studies between 1966 and 1970 compared the combination of an antipsychotic and chlordiazepoxide with an antipsychotic alone in newly hospitalized acutely psychotic patients at Spring Grove State Hospital in Maryland and found that the combination drug treatment was less effective than the antipsychotic alone (Hanlon et al., 1969, 1970; Michaux et al., 1966). In an open trial comparing chlorpromazine, chlordiazepoxide, and placebo in 30 schizophrenic patients, 4/10 treated with chlordiazepoxide alone improved with regard to psychotic symptoms; also, chlordiazepoxide in combination with an antipsychotic was more effective than the antipsychotic alone in regard to thought disorder and motor behavior (Hekimian & Friedhoff, 1967). Consistent with these observations is a report showing that the addition of chlordiazepoxide to an antipsychotic regimen was effective in controlling acutely psychotic, episodically dyscontrolled patients (Monroe & Wise, 1965). Another group of investigators reported that chlordiazepoxide was not effective in the treatment of psychosis and that most changes in global ratings were due to the sedative and calming effects of chlordiazepoxide (Holden et al., 1968). Finally, a report on 6 schizophrenic patients concomitantly treated with neuroleptics found that 3/6 patients demonstrated an adequate response. Overall, the response rate with chlordiazepoxide in psychotic illnesses among 75 patients is just over 50%, but over half of these patients also were treated with neuroleptics. Therefore, conclusions regarding efficacy of chlordiazepoxide alone must be tentative.

Benzodiazepine Toxicity in Psychotic Illnesses

A review of seven publications (Beckman & Haas, 1980; Haas et al., 1982; Hollister et al., 1963; Jimerson et al., 1982; Karson et al., 1982; Lerner et al., 1979; Maculans, 1964) revealed a variety of side effects reported with both diazepam and clonazepam in a total of 114 patients (Table 3). Except for the final study cited which reported on manic patients (Chouinard et al., 1983), all patients were reportedly schizophrenic. However, the diagnostic criteria employed varied and many of these may have fallen in the affective spectrum if DSM-III (Diagnostic and Statistical Manual—3rd ed., 1980) were being used. In this group of patients, it was evident that the two general types of side effects seen in these reports included sedation/quieting and arousal/stimulation. This preliminary literature review would suggest that certain benzodiazepines may have a significant likelihood of producing sedation or stimulation in certain psychotic patients. The particular pattern of behavioral toxicity in an individual may be idiosyncratic, or may be mediated via other poorly understood factors not readily apparent in the limited sample reviewed.

It is of note that the arousal/stimulation pattern of toxicity seen in a number of schizophrenic patients is reminiscent of manic symptoms, i.e., hypersexuality, hyperkinesis, excitation, euphoria, and impulsive behavior. This would suggest that caution must be exercised in interpreting these symptoms in diagnostically complicated cases who are treated with benzodiazepines during the clinical evaluation period. This arousal pattern seen with the use of certain benzodiazepines in chronically psychotic individuals may confound the diagnostic process, as is mentioned in the Discussion section.

Preliminary Clinical Results With the Use of Lorazepam in Psychotic Illnesses

Retrospective Chart Review of Patients Treated With Neuroleptics and Lorazepam Over a 6-Month Period

Between January 1984 and July 1984 a total of 380 patients were admitted to one of three 22-bed acute inpatient units in the Department of Psychiatry at the Boston Veterans Administration Medical Center. When clinically indicated, patients were treated

TABLE 3

Toxicity Reported With Benzodiazepines in Psychotic Disorders

TABLE 4

Neuroleptic Dose Requirements in Psychotic Disorders: Neuroleptics With and Without Lorazepam (LZP)

Treatments	*N* (Total = 30)	CPZ-EQ (mg)* (mean ± SEM)
A Neuroleptics	22	560 ± 85
B Neuroleptics + LPZ [a]	8	265 ± 50

*Chlorpromazine-equivalents/24 hrs./patient; doses were at discharge and were determined to be lowest dose for effective control of psychotic target symptoms.
[a] Mean lorazepam dose = 2.75 mg/24 hrs.
Statistical Data:
B vs. A: $t = 2.99$; df = 28; $p < .01$

with doctor's choice of neuroleptic, doses being tapered continuously during hospitalization to achieve the lowest effective dose. Of the 380 admissions, it was found that 30 patients were discharged with either neuroleptic or neuroleptic with lorazepam at the lowest doses clinically possible without an exacerbation of symptoms. Mean discharge dose of neuroleptic was comparable for the three units as was average length-of-stay. Patients with a significant degree of agitation initially were treated with lorazepam and were discharged with the lowest effective dose of this compound.

Table 4 presents the neuroleptic dosages employed, converted to chlorpromazine-equivalents (CPZ-EQ) (Baldessarini, 1980), on these 30 patients separated into treatment groups: 1) neuroleptics, and 2) neuroleptics with lorazepam. In 22 patients discharged on neuroleptics alone, mean CPZ-EQ/day was 560 mg whereas in 8 patients treated with both neuroleptics and lorazepam (mean lorazepam dose = 2.75 mg/day), the mean CPZ-EQ/day on discharge was 265 mg, a difference found to be statistically significant ($t = 2.99$; df = 28; $p < .01$). Data on 32 patients not shown were separated into two other treatment subgroups: 1) neuroleptics and benztropines, and 2) neuroleptics, lorazepam, and benztropine. The group of patients treated with both neuroleptics and benztropines ($N = 18$; mean dose benztropine = 2.2 mg) had a mean CPZ-EQ dose of 771 mg/day (SEM ± 164). The group of 14 patients treated with neuroleptics, lorazepam, and benztropine had a mean CPZ-EQ dose of 933 mg (SEM ± 227) (*see* Table 4).

Although patients were tapered to lowest effective dose for treatment of psychotic symptoms, the heterogeneity of the population made it difficult to separate dose requirement of neuroleptic from severity of illness. Because lorazepam was initiated for agitation and irritability, it is unlikely that this cohort represented less severe forms of psychosis although, without controlling for severity, this assumption remains untested. The dose of neuroleptics in the group receiving concomitant lorazepam therapy was clearly lower than the other group shown. This lower dose of neuroleptics also may have led to a lower incidence of extrapyramidal side effects and/or akathisia, therefore not requiring the use of benztropine. This reduced requirement for neuroleptics may have reduced the incidence of neuroleptic-induced toxicity which may have reflected itself as an overall improved clinical picture at relatively lower doses of antipsychotics. Further research with carefully controlled groups of psychotic patients with uniform symptom profiles on fixed doses of neuroleptics is needed to assess whether there is a significant interaction between these two medications which allows for use of lower doses of neuroleptics. Also, it remains to be assessed whether the reduced neuroleptic dose lowered the incidence of neuroleptic-induced side effects, i.e., akathisia, hence leading to apparent efficacy which, in fact, was reduced toxicity.

Preliminary Results of the Efficacy and Toxicity of Lorazepam in 14 Psychotic Patients

Preliminary results from an ongoing study on the efficacy of lorazepam vs. lorazepam with haloperidol for psychotic disorders were reviewed. Acutely psychotic patients between the ages of 18 and 65 were admitted to a research inpatient service at the Boston Veterans Administration Medical Center, underwent a complete battery of clinical and laboratory tests to exclude active medical conditions, and were stabilized with regard to diet and fluid intake. Subjects able and willing to sign informed consent were observed clinically for 48 hours following admission and rated daily with the Brief Psychiatric Rating Scale (BPRS) to determine the nature and intensity of psychotic symptoms. Those patients who demonstrated a clear improvement in psychotic symptomatology in this time period were excluded from study and the remaining patients were treated either with lorazepam or lorazepam with haloperidol. Blood samples for analysis of lorazepam and haloperidol were drawn into heparin-containing tubes, centrifuged, separated, and kept frozen at −20° C until assay. Lorazepam was measured by gas liquid chromatography with electron-capture detection (Greenblatt et al., 1978); haloperidol was measured by gas liquid chromatography with a nitrogen-phosphorus detector (Abernethy et al., 1984).

Table 5 presents data on the 14 patients studied including basic demographics, diagnostic data, doses of lorazepam and haloperidol employed, and specific items on the BPRS showing significant improvement over the 48-hour period of treatment. Diagnostic evaluations were performed by a research psychiatrist and a research assistant employing DSM-III criteria with the aid of the Structured Clinical Interview for DSM-III (SCID). Eight patients with diagnoses of mania ($N=4$), schizophrenia ($N=3$), and atypical psychosis ($N=1$) were treated with a mean dose of 20.9 mg/day of lorazepam alone and demonstrated a mean drop in BPRS scores of 20; BPRS items showing significant improvement ($p<.05$) were tension, hostility, suspiciousness, hallucinations, unusual thoughts, conceptual disorganization, excitement, and emotional withdrawal. Six patients divided equally between mania, schizophrenia, and atypical psychosis were treated with both lorazepam and haloperidol. The mean lorazepam dose was 16.5 mg/day and mean haloperidol dose was 14.2 mg/day. The items on the BPRS which showed significant improvement were grandiosity, unusual thoughts, conceptual disorganization, blunted affect, and emotional withdrawal ($p<.05$).

In order to assess the differences between high-dose (>30 mg/day; $N=3$) vs. low-dose (<10 mg/day; $N=5$) lorazepam among the lorazepam-treated group ($N=8$), and to assess the differences between low-dose lorazepam ($N=5$) vs. low-dose lorazepam with low-dose haloperidol ($N=4$), clinical response data were analyzed in this same cohort of patients (*see* Table 6; N.B. Two patients treated with lorazepam and haloperidol who were included in Table 5 were treated with >20 mg/

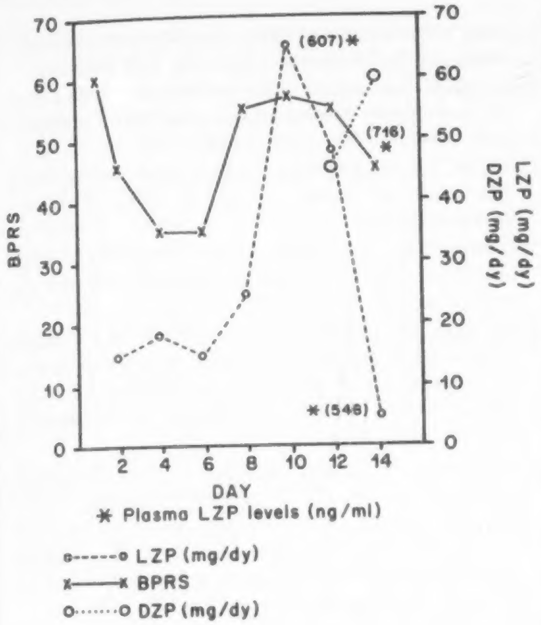
day of lorazepam and were not included in the data analysis in Table 6). Mean daily lorazepam dose in the high-dose lorazepam group was 45 mg with a mean plasma level of 688 ng/ml. Nonpsychotic symptoms that were significantly improved included tension, hostility, and excitement; psychotic symptoms showing improvement were suspiciousness and conceptual disorganization. In the group receiving high-dose lorazepam, significant worsening in motor retardation and blunted affect was noted. The low-dose lorazepam group ($N=5$) received a mean daily dose of 6.2 mg/day with mean plasma levels of 29.5 ng/ml. Clinical improvement was noted with excitement, unusual thoughts, and emotional withdrawal. The 4 patients treated with both lorazepam and haloperidol were treated with mean doses of 5 mg/day and 15 mg/day, respectively. Improvement was noted in conceptual disorganization, unusual thoughts, and emotional withdrawal.

Time Course of Treatment Response of a Manic Patient

The Figure (p. 85) outlines the 2-week course of a 42-year-old white male, bipolar manic patient treated only with lorazepam and diazepam over a 14-day period. Presenting symptoms on admission included paranoia, grandiosity, insomnia, loss of appetite, restlessness, agitation, labile affect, pressured speech, racing thoughts, and poor judgment. The total BPRS score on admission was 60. By history, this episode began 4 months prior to admission.

The patient was begun on 8 mg oral lorazepam daily with 2 mg doses administered as needed for agitation. A BPRS to assess severity of psychosis and response to treatment was completed daily by a research psychiatrist. Within the first 24 hours of treatment, he received 15 mg of lorazepam and showed moderate improvement in symptoms such as



uncooperativeness, excitement, and suspiciousness as defined by a 2-point decrease on BPRS subscales. After 48 hours of treatment, total BPRS score had dropped to 33. There continued to be marked improvement in grandiosity, tension, unusual thought content, and conceptual disorganization through day 6. Unexpectedly, between day 6 and day 8, with little change in daily lorazepam dose (between 16 to 24 mg) he demonstrated a clear worsening in his clinical state as reflected in increasing BPRS scores with manic symptoms similar to those evident on admission (*see* Figure). The lorazepam dose was increased to 65 mg daily with a plasma lorazepam level of 607 ng/ml with no improvement in psychotic symptoms. Because of his failure to respond, lorazepam was rapidly tapered and on day 12, diazepam was started in order to avoid possible withdrawal symptoms from the high-dose lorazepam regimen. On day 15, haloperidol treatment was initiated with marked improvement in 3 days and remission in 2 weeks.

This case characterizes the time course observed with other psychotic patients treated with lorazepam in whom rapid improvement is not sustained beyond 4 to 6 days, with little benefit attained by increasing lorazepam dosage. This was evaluated with lorazepam levels which confirmed that drug levels increased with increasing dosage. Because antipsychotic effect was not attained with increased levels of lorazepam, this would not suggest that tolerance was developing to the antipsychotic effect of lorazepam. Further clinical and preclinical work is needed to better understand this pattern of clinical effect in psychotic illnesses.

Discussion

It is evident from this literature review that benzodiazepines are not as effective in the treatment of psychotic disorders as neuroleptics or lithium salts. The efficacy rate of benzodiazepines for the treatment of psychosis, usually reported as schizophrenia (not necessarily DSM-III), is approximately what would generally be expected from placebo rates of response (Tables 1 and 2; 98/278 = 35.2%). Because many of these reports were retrospective and/or included patients concomitantly treated with neuroleptics or lithium, the actual response rate may be lower than the apparent 35.2%.

Toxicity seen when psychotic disorders were treated with benzodiazepines included the expected sedation and drowsiness characteristic of this class of medication (32%), but also included arousal and excitation (34%) manifesting as manic symptoms in some cases and, more seriously, as assaultive behavior in others. Clinicians employing benzodiazepines for behavioral management of psychotic patients need to be alerted to this potentially confounding effect of these drugs. The literature would suggest that schizophrenia mistakenly may be seen as an affective psychosis if the clinician is not aware of these patterns of toxicity. An alternate view would hold that benzodiazepines, like tricyclic antidepressants or monoamine oxidase inhibitors, may produce a "switch" phenomenon (Goodwin, 1983) and what may have appeared initially as schizophrenia may be affective illness "unmasked" by the benzodiazepine. Because there is little evidence presently to support this hypothesis, more research is needed to delineate the meaning of the arousal evident in psychotic disorders treated with benzodiazepines.

The preliminary findings in 14 psychotic patients treated with lorazepam alone would suggest that this compound may be helpful initially (48 hours) for the treatment of acutely psychotic individuals. This effect was seen both with high- and low-dose lorazepam, the high-dose regimen apparently quite effective for a range of behavioral, affective, and cognitive symptoms of psychosis, but also more likely to cause motor retardation and blunted affect. The pattern seen in the Figure is representative of many patients we have observed in which the rapid initial improvement in psychotic symptoms is short-lived and does not respond to increasing the dose of lorazepam.

Our retrospective chart review revealed that combined neuroleptic and lorazepam treatment required significantly lower doses of neuroleptic (CPZ-EQ = 265 mg) as compared to neuroleptics alone (CPZ-EQ = 560 mg). This finding would suggest that further work is needed to assess whether combined neuroleptic and lorazepam regimens would allow for the use of lower doses of neuroleptics to achieve comparable clinical effects, i.e., a shift to the left of the dose-response curve for neuroleptics in psychosis.

New Strategies for the Treatment of Alcohol Withdrawal

E.M. Sellers, Ph.D.,[1] and C.A. Naranjo, Ph.D.[1]

Introduction

The goals in the treatment of alcohol withdrawal are the relief of subjective symptoms, the prevention or treatment of the serious complications (e.g., seizures, hallucinations, arrhythmias, and delirium), and preparation for long-term rehabilitation. Such treatment should be standardized, humane, as simple and economic as possible, and it should have a pharmacokinetic and pharmacodynamic rationale.

Over the past 10 years we have conducted studies directed toward the development of trial methodology and diagnostic and tracking criteria of the withdrawal syndrome, the determination of the natural history of the withdrawal syndrome, the assessment of the importance of nonpharmacologic treatment measures, the simplification of drug therapy, and the determination of the role of adjunctive drugs, such as phenytoin. Recently, we have been testing the hypothesis that the pharmacotherapy of alcohol withdrawal can be improved by the use of selective, nonsedating drugs.

Diagnostic Criteria and Scales to Track the Clinical Syndrome

In an effort to develop an instrument for assessing the alcohol withdrawal syndrome, Gross et al. (1973, 1974) identified disturbances in 30 clinical variables during experimental alcohol withdrawal studies. Two instruments were developed: a research battery (total severity assessment, TSA) and a clinical instrument (selected severity scale, SSA). The TSA contained all of the original 30 clinical variables, while the SSA consisted of a short list of 11 items. The SSA correlated highly with the TSA (Gross et al., 1973, 1974); however, full prospective validation of the SSA was not done. We modified this scoring system for rapid repeated use (Shaw et al., 1981). Our 15-item scale, Clinical Institute Withdrawal Assessment for Alcohol (CIWA-A) includes tremor; nausea and vomiting; paroxysmal sweating; tactile, auditory, and visual disturbances; hallucinations; quality of contact; anxiety; agitation; thought disturbances; seizures; headache; and flushing of face (Shaw et al., 1981). Heart rate, temperature, and blood pressure are also recorded, but not included in the scoring.

Several prospective studies show that the CIWA-A scale is valid, reliable, and sensitive (Naranjo et al., 1983; Sellers et al., 1983; Shaw et al., 1981). CIWA-A scores correlate with physician global ratings of withdrawal severity. Nine items in particular contribute most weight to the total score (nausea; tremor; sweating; tactile, auditory, and visual disturbances; hallucinations; anxiety; and agitation) and correlate highly with the total score ($r = 0.95$). Inter-rater and intra-rater reliability has been determined ($r = 0.8$–0.92). The scale has been successfully used in assessing the therapeutic response in clinical trials in ambulatory and hospitalized patients in withdrawal (Naranjo et al., 1983; Sellers et al., 1983; Shaw et al., 1981). Several other advantages of this standardized procedure are that medical and other health workers become aware of the symptoms that make up the alcohol withdrawal syndrome, and staff training is facilitated. Because of its brevity, this procedure can be incorporated into "routine" patient care. We are currently testing whether validity and reliability can be retained with a further simplification of the scale (i.e., reduction of number of items) and change in the scoring ranges (Sullivan et al., 1985).

Nonpharmacologic Interventions

Uncontrolled studies showed that reassurance, reality orientation, frequent monitoring of signs and symptoms, personal attention, and general nursing care can be effective in over two-thirds of patients in a mild alcohol withdrawal reaction (Toshney, 1978; Whitfield et al., 1978).

Recent controlled studies using a standardized form of "supportive care" have confirmed the potency of such nonpharmacologic interventions (Naranjo et al., 1983; Sellers et al., 1983; Shaw et al., 1981). Eighty-five percent of emergency room patients (Naranjo et al., 1983) and 75% of inpatients without, and 56% with, medical complications respond to supportive care in less than 6 to 8 hours (Sellers et al., 1983).

The effectiveness of nonpharmacologic interventions has important implications for design and interpretation of studies assessing drug therapies in alcohol withdrawal. In this context, it is notable that the frequency of placebo-controlled studies of alcohol withdrawal has declined markedly. Placebos were used in 11 of the 19 controlled studies published during the 1960's but in only 4 of the 19 in the 1970's (Gessner, 1979). Since our data indicate that, to a substantial extent, the apparent efficacy of a drug can be due to the influence of nonpharmacologic interventions, it is essential to use a placebo control group (Naranjo et al., 1983).

Even though supportive care decreases the general symptoms of withdrawal, it does not appear to completely prevent hallucinations, seizures, or arrhythmias; hence, drugs are still required by patients. Since patient characteristics do not predict the occurrence of such complications, patients in moderate to severe withdrawal should receive drugs such as diazepam in addition to supportive care (Sellers et al., 1983).

Dosage Strategies and Pharmacotherapy

Benzodiazepines are currently the drugs of choice (Linnoila, 1983; Sellers & Kalant, 1976, 1982; Sellers et al., 1983). They combine at least equal efficacy as other agents with superior anticonvulsant activity and less toxicity than phenothiazines, barbiturates, and paraldehyde (Sellers & Kalant, 1982). Numerous benzodiazepines including alprazolam, bromazepam, chlordiazepoxide, chlorazepate, clobazam, diazepam, flurazepam, lorazepam, and oxazepam, have been studied and all can be effective (Linnoila, 1983; Moskowitz et al., 1983; Sellers & Kalant, 1976, 1982). Approximate equivalent doses relative to chlordiazepoxide 100 mg are diazepam 20 mg, oxazepam 120 mg, and lorazepam 5 mg.

Both chlordiazepoxide and diazepam are long-acting drugs with pharmacologically active metabolites (Greenblatt et al., 1983). Repeated daily administration at a constant dosage would result in cumulation of the parent compound and/or metabolites in the body (Sellers & Kalant, 1976; Sellers et al., 1983). Such a dosing regimen could delay the onset of maximum therapeutic and unwanted toxic effects for several days. Similar cumulation would occur with prazepam or chlorazepate which are biotransformed to desmethyldiazepam, the pharmacologically active long half-life metabolite formed after diazepam administration (Sellers & Kalant, 1976; Victor, 1966). If dosages are not adjusted carefully, excessive drowsiness, lethargy, ataxia, diplopia, and confusion may occur.

The usual strategy to avoid such side effects is to give larger doses on the first day and progressively lower the dose on subsequent days (Sellers & Kalant, 1976). Typically, multiple doses of diazepam (20 to 40 mg) or chlordiazepoxide (100 to 400 mg) are given on the first day (Sellers & Kalant, 1976, 1982). Lower doses were given daily thereafter and dose-tapering decreased by about 25% to 50% of the initial daily dose (Sellers & Kalant, 1976; Sellers et al., 1983). However, because of variability in the severity of withdrawal symptoms and in the metabolic disposition of the drugs, strict adherence to such dosage schedules may cause toxicity or ineffective treatment in some patients (Sellers et al., 1983). Recently, the dose-tapering approach to treating alcohol withdrawal has been further simplified (Sellers et al., 1983).

The procedure consists of a rapid oral loading-dose strategy using diazepam. Patients are assessed clinically or with the CIWA-A scale and unit doses of 20 mg of

TABLE

Diazepam Loading Trial*
Complications-Placebo Group Only

Subject Trial #	Complication	Time (Hour)
245	Seizure	3
213	Supraventricular tachycardia	2
222	Seizure	7.5
211	Hallucinations	7.5
201	Severe vomiting/anxiety	6
240	Seizure × 3	6

*Sellers et al., 1983.

diazepam, orally, are administered every 1 to 2 hours until the patient shows clinical improvement (CIWA-A<10) or becomes mildly sedated. The rationale of this approach is to take advantage of rapid and complete absorption of diazepam and the pharmacokinetic tapering afforded by diazepam's and N-desmethyldiazepam's long half-lives, i.e., 30 and 40 hours, respectively (Sellers et al., 1983). This pharmacokinetic "umbrella" of active drug is eliminated at about the same rate as the resolution of the withdrawal syndrome.

In a recent double-blind controlled study, patients treated with diazepam using the loading-dose approach had a faster and greater improvement than those receiving placebo (Sellers et al., 1983). Fifty percent of the patients responded to 60 mg of diazepam orally within 7.6 hours, and only an occasional patient required treatment for more than 24 hours. More importantly, complications (seizures, hallucinations, arrhythmias) occurred exclusively in those treated with placebo, indicating that delay in therapy may be responsible for the appearance of complications in withdrawal (Sellers et al., 1983) (*see* Table). We recommend that all hospitalized patients in moderate to severe withdrawal should be loaded with at least 60 mg of diazepam.

Treatment of Alcohol Withdrawal Seizures

The optimal treatment of alcohol withdrawal seizures remains controversial (Gessner, 1974; Naranjo, 1983; Sellers & Kalant, 1982; Thompson, 1978). In particular, the therapeutic and prophylactic value of phenytoin in alcohol withdrawal seizures is uncertain. The contradictory findings in the reported clinical studies possibly arise from the indiscriminate inclusion of patients with pre-existing seizure disorder and those with a previous history of withdrawal seizures only, as well as the failure to standardize and give sufficient benzodiazepine or other drugs as "baseline therapy" (Rothstein, 1973; Sampliner & Iber, 1974; Sandor et al., 1981).

To further investigate this, we have conducted studies in laboratory animals (Solorzano et al., 1985). To determine if phenytoin exhibits pharmacologic selectivity or augments the activity of diazepam in alcohol withdrawal syndrome, male Long-Evans rats were made physically dependent by the administration of intragastric ethanol (3 to 5 g/kg) twice daily for 6 days (Rothstein, 1973). In animal models of alcohol withdrawal, diazepam and phenytoin can be protective against audiogenic seizures; however, the two drugs differ in potency and intrinsic activity. For example, diazepam (3.0 mg/kg) will decrease seizures by up to 50% whereas phenytoin (100 mg/kg) can completely abolish seizures. For phenytoin, a 50% reduction in seizures occurs at 35 mg/kg.

With respect to combinations of diazepam and phenytoin, lower doses of phenytoin (25 mg/kg) plus diazepam (1.0 mg/kg) are more effective than diazepam alone and approximately equal to phenytoin (100 mg/kg) (Rothstein, 1973).

From these studies, one can suspect that diazepam's anticonvulsant action will be sufficient when seizure risk is low, but that phenytoin could increase diazepam's anticonvulsant action in a clinically important way. This will be true, however, only as long as full therapeutic doses of phenytoin are given. However, about 30% of dosing in chronic alcoholics is not straightforward, because chronic alcoholics have clearances of phenytoin that are two- to three-fold greater than normal (Sandor et al., 1981). Hence, daily maintenance doses must be increased to 600 to 900 mg/day to maintain adequate steady-state concentrations. Since some chronic alcoholics may have impaired clearance, daily measurement of phenytoin concentrations is imperative to use this drug properly (Sandor et al., 1981).

In our clinical studies, we have been impressed that patients who have received an adequate diazepam load (i.e., 60 mg or more) do not have seizures even though they may have a relatively strong history of withdrawal seizures (Sellers et al., 1983). In most patients without a previous history of seizures, benzodiazepines alone probably have sufficient anticonvulsant activity to prevent withdrawal seizures (Sellers et al., 1983). Phenytoin is reserved for patients with epilepsy or a history of recurrent or severe withdrawal seizures. A recent uncontrolled open study in 20 "high-risk" seizure patients is consistent with this approach and reiterates our previous advice (Devenyi & Harrison, 1985).

Future Treatment Strategies

Past studies that have attempted to use drugs with greater selectivity in the treatment of alcohol withdrawal have not been terribly encouraging. Lithium decreased only a few subjective symptoms (Sellers et al., 1976). Propranolol decreased tremor, heart rate, and anxiety; however, it caused an increased frequency of hallucinations (Jacob et al., 1983; Sellers et al., 1977). Clonidine appeared to be minimally effective or to actually increase the frequency of clinical seizures (Bjorkqvist, 1975; Blum et al., 1983). If drugs could be developed that were anxiolytic and anticonvulsant and at the same time had a decreased risk of sedation, interaction with ethanol or other central nervous system depressants, and dependence liability, some advances in therapy could occur. A number of newer anxiolytics of the benzodiazepine type and non-benzodiazepine type appear to demonstrate some selective anxiolytic properties (Lippa et al., 1982; Solorzano et al., 1985).

Irrespective of whether more selective drugs will prove to have therapeutic advantages, the methodologic standards for clinical trials in this area have been established. Clinical scales such as the CIWA-A should be used to quantitate drug effects (Shaw et al., 1981). There must be a clear specification of the supportive care given. The importance of such care can be estimated by the inclusion of a placebo-control group. Such a group is necessary because of the potential magnitude of the supportive care effect. In light of the simplification achieved through the diazepam loading-dose technique, it seems likely that other optimal drug therapy strategies for alcohol withdrawal should employ a similar type of titration technique. For this to be clinically feasible, a new drug should be rapidly absorbed and have an intermediate to long half-life in order to avoid withdrawal rebound.

Acknowledgments: We thank our students and other collaborators for their contribution to our studies: Drs. L. Solorzano, H. Kaplan, J. Schneiderman, P. Devenyi, D. Donat, and Ms. J. Shaw, Ms. M. Harrison, and Ms. C. Hamilton. In addition, we thank Ms. D. Campbell and Ms. Karen Cauch-Bontje for their typing and editorial assistance.

Benzodiazepines for Treatment of Panic Attacks: A New Look[1]

Karl Rickels, M.D.,[2] and Edward E. Schweizer, M.D.[2]

Introduction and Recent Literature

Panic disorder (PD) has only recently emerged as a distinct psychiatric diagnosis with the advent of DSM-III (American Psychiatric Association, 1980). Its separate status is largely an American nosological refinement, not yet officially sanctioned in Europe (Editorial, 1983). Under DSM-II (American Psychiatric Association, 1952), patients with panic presentations had been categorized under a diagnosis of either Anxiety Neurosis or Phobic Neurosis, depending on the degree of concurrent phobic avoidance behavior or agoraphobia.

The impetus for this new subtyping of anxiety stemmed from Klein (1964) and his associates (Zitrin et al., 1978, 1983) who first observed a preferential treatment response to the tricyclic antidepressant imipramine over benzodiazepines in a subset of anxious patients with crescendo anxiety associated with agoraphobia. Other researchers confirmed the utility of antidepressants in panic patients with agoraphobia and extended it to include monoamine oxidase (MAO) inhibitors such as phenelzine (Liebowitz et al., in press; Sheehan et al., 1984b). Various behavior therapies (Marks, 1976; Mavissakalian & Michelson, 1982) also proved beneficial in the treatment of such patients.

We thus have a new anxiety diagnosis—PD, with or without complicating agoraphobia—that owes its existence, in no small measure, to research suggesting the relative *ineffectiveness* of traditional benzodiazepine anxiolytics and the relative superiority of certain antidepressants in its treatment.

With the exception of alprazolam, the lack of specific effectiveness of other benzodiazepines in panic states has, in recent years, become an almost unquestioned assumption in much of clinical practice. It is a rather sweeping generalization, though, based on slim scientific evidence indeed. We are aware of only two well-controlled studies assessing the efficacy of non-triazolobenzodiazepines in PD: one is a negative, and one a positive study.

McNair and Kahn (1981) reported that chlordiazepoxide (60 mg/day) was significantly less effective in alleviating symptoms of PD than was imipramine. In contrast, Noyes et al. (1984) compared, in a 2-week, double-blind crossover study, diazepam with propranolol in patients suffering from panic disorder accompanied by various degrees of phobic avoidance behavior. They reported a significant reduction in number and intensity of panic symptoms, phobic symptoms, and social impairment in patients being treated with diazepam in the usual therapeutic daily dosage, but not in patients treated with the beta blocker propranolol (Table 1).

The question that arises is: what is the role of the benzodiazepines in PD, if any? Is it merely as a minor adjunct to antidepressant

TABLE 1

Mean (± SE) Number and Severity of Panic Attacks and Severity of Phobic Symptoms and Social Impairment During Drug Therapy

	Baseline	Propranolol Week 2	Diazepam Week 2
Panic Attacks ($N = 17$)			
Number	8.5 ± 2.79	6.4 ± 1.26	2.9 ± 0.84
Severity	2.2 ± 0.20	2.0 ± 0.19	1.2 ± 0.26
Phobic Symptoms ($N = 19$)			
Severity	2.2 ± 0.21	1.6 ± 0.27	1.0 ± 0.19
Social Impairment ($N = 21$)			
Severity	2.2 ± 0.18	1.9 ± 0.18	1.0 ± 0.26

From Noyes et al., *Arch. Gen. Psychiatry*, 41:287, 1984 treatment? Do triazolo compounds such as alprazolam have a unique treatment specificity? Do associated features such as degree of phobic avoidance behaviors or degree of generalized or anticipatory anxiety have a bearing on drug choice or treatment response? From most literature reporting on the treatment of panic attacks and agoraphobia, it is quite difficult to determine whether patients included in these studies suffered primarily from PD *without* agoraphobia or from PD *with* agoraphobia. Thus, no answer presently exists to the important clinical question of whether benzodiazepines, prescribed in therapeutic dosages, are effective agents in the treatment of patients suffering from PD without marked agoraphobia. In the succeeding sections the authors will comment on some of these issues.

Alprazolam in Panic Disorder

Sheehan (1984a) conducted the first study of alprazolam in PD and agoraphobia. It was an uncontrolled, single-blind, crossover study comparing ibuprofen (Motrin) versus alprazolam which indicated that alprazolam was more effective in reducing PD symptoms than ibuprofen. In another larger and double-blind controlled study, Sheehan then compared alprazolam with imipramine, phenelzine, and placebo in patients suffering from PD and/or agoraphobia (Sheehan et al., 1984b) and observed that all three active agents produced significantly more improvement than placebo. Again, patients suffering only from PD were not differentiated from those suffering from both PD and agoraphobia. Chouinard et al. (1982) compared alprazolam with placebo under double-blind conditions in two groups of patients, those suffering from PD and those suffering from generalized anxiety disorder (GAD). Using the Hamilton Anxiety Scale (HAM-A) as outcome criterion, Chouinard et al. (1982) observed that alprazolam was equally effective in PD and in GAD but that placebo appeared slightly more effective in GAD than in PD patients. Medications were prescribed within Food and Drug Administration (FDA) recommended dosages.

Several years ago the Upjohn Company instituted a large controlled trial comparing the effects of alprazolam prescribed in dosages up to 10 mg/day versus placebo in PD patients with and without secondary phobic avoidance behavior or agoraphobia. The Upjohn study was conducted in a multinational, multicenter fashion and its preliminary results have recently been reported (Ballenger et al., 1985). Alprazolam, when prescribed in higher than recommended therapeutic dosages for the treatment of GAD, produced significantly more improvement than placebo in all aspects of behavior assessed, be it anxiety, number and intensity of panic attacks, phobic avoidance behavior, or work and family adjustment. However, no evidence as to whether or not alprazolam's effectiveness depended on the intensity of the agoraphobic condition present was presented.

The effective dosage range of alprazolam for panic appears, from these studies, to be 6 to 8 mg/day (though doses up to 10 mg or higher have not infrequently been required). On an equipotent basis, this translates into a diazepam dose of 60 to 100 mg/day or higher. Controlled studies of benzodiazepines in panic using equipotent dosages have, to our knowledge, not yet been conducted.

Non-Triazolobenzodiazepines and Panic Disorder: Some New Data

Recently, one of the present authors (Schweizer) treated 5 patients diagnosed by SCID-UP (Structured Clinical Interview for DSM-III Diagnosis—Upjohn) as suffering from PD with lorazepam in an open-label trial. Patients with moderate to severe degrees of agoraphobia were excluded, as were patients suffering from concomitant depression. Dosing was begun with lorazepam 0.5 mg three times a day (t.i.d.) and then gradually increased to a daily dose of 3 to 8 mg, i.e., the same dosage range as recommended for the treatment of GAD. Improvement was monitored by both the HAM-A and a Panic Attack Diary. Four of five patients obtained more than 80% control of panic attacks associated with a reduction in Hamilton scores to <8. Some well-controlled double-blind stud-

TABLE 2

Intake Criteria for Studies A and B

1) HAM-A $\geq$ 18
2) Covi-Anxiety $\geq$ 8
3) Raskin Depression < Covi-Anxiety
4) 17-item Anxiety Entry Checklist (FDA): $\geq$5 items
5) Duration of symptoms:
    Study A: >3 months
    Study B: >1 month
6) DSM-II anxiety diagnosis (patient later reclassified according to DSM-III)
7) Excluded:
    a) Phobic disorders including marked agoraphobia
    b) Depressive disorders
8) Considered by psychiatrist to be in need of anxiolytic treatment
9) Diazepam dosage (~25 mg/day)

ies presently under way at several clinical research centers should be able to confirm or refute the antipanic effects of such non-triazolobenzodiazepines as diazepam and lorazepam.

Since patients suffering from panic disorder without marked agoraphobia were diagnosed prior to the introduction of the DSM-III in 1980 as belonging to the large group of patients suffering from anxiety neurosis, the authors felt it important to review two studies conducted by their research group prior to 1980, and to divide all anxious patients into those with and those without panic symptoms. It should be stressed, however, that patients who received a DSM-II diagnosis of phobic neurosis, which would have included agoraphobia, were excluded from these studies.

Hopkins Symptom Checklist (HSCL) (Derogatis et al., 1974) data were available for both studies. Entry criteria employed in these studies are given in Table 2, and the items which make up the HSCL anxiety and panic factors are given in Table 3. The HSCL anxiety factor was further divided into a GAD subfactor and a PD subfactor, as only one of the two studies included the HSCL panic factor as a criterion measure.

Table 4 reports 6 weeks' improvement results obtained in the first of the two reviewed studies (Rickels et al., 1983). Diazepam was the treatment agent and the HSCL anxiety factor, its two subfactors, and the HSCL panic factor were used as outcome criteria. Patients improved highly significantly in all measures. When analyzing only the subgroup of patients scoring high on the HSCL panic factor ($\geq$1.60) (Table 5), even more significant improvement was observed in both general anxiety and panic anxiety symptoms.

Table 6 presents results obtained in the second study (Rickels et al., 1982). Diazepam and placebo treatment outcome was compared as a function of initial level of panic symptoms as assessed with the HSCL panic subfactor. (A score of $\geq$1.60 was considered high panic level.) Table 6 clearly indicates no evidence for a drug X panic level interaction, only highly significant main drug effects, with anxious patients improving significantly more on diazepam than on placebo, irrespective of their initial level of panic symptomatology.

Some additional evidence of the usefulness of benzodiazepines in the treatment of PD

TABLE 3

Hopkins Symptom Checklist (HSCL) Anxiety and Panic Factors

HSCL-Anxiety Factor	HSCL-Panic Factor
GAD Subfactor:	
1. Nervousness or shakiness inside	1. Feeling afraid in open spaces or on the streets
2. Trembling	2. Feeling afraid to go out of the house alone
3. Feeling fearful	3. Feeling uneasy in crowds, such as shopping or at a movie
4. Feeling tense or keyed up	4. Feeling afraid of fainting in public
	5. Feeling afraid to travel on buses, subways, or trains
Panic Subfactor:	6. Feeling nervous when left alone
1. Suddenly scared for no reason	
2. Heart pounding or racing	
3. Having to avoid certain things, places, activities because they frighten me

TABLE 7

Psychiatric Diagnosis of Chronic Benzodiazepine Users When Initiating Anxiolytic Therapy

Diagnosis	Percent
Anxiety	40
Panic	31
Depression	20
Other	3
No Diagnosis	6

comes from a study of 117 long-term chronic benzodiazepine users (in preparation). Preliminary results obtained for the first 31 of these 117 patients were recently reported (Rickels et al., 1984). An intensive psychiatric history, including an administration of the SADS-L, indicated that 31% of 117 patients who initiated benzodiazepine therapy many years ago started their treatment because of symptoms closely resembling panic attacks (Table 7). When these 117 patients were asked prior to benzodiazepine withdrawal whether they were deriving any benefit from their benzodiazepine medication, about 80% of those originally diagnosed as suffering from GAD and 72% of those originally diagnosed as suffering from PD, but only 40% of those originally diagnosed as suffering from depressive states, claimed that they had derived significant benefit from treatment with various long as well as short half-life benzodiazepines.

These data seem to indicate to the authors that the recent "discovery" of the beneficial effect of the benzodiazepine alprazolam in the treatment of PD does not seem to be unique for alprazolam, but may also be true for some of the older benzodiazepines.

Comments

Several points of clinical interest may be deduced from the data presented.

1. Klein's (1964) earlier observation that "anticipatory anxiety" of agoraphobic patients is beneficially influenced by benzodiazepine supports the benzodiazepines' efficacy in GAD, as Klein's anticipatory anxiety would probably be diagnosed within the framework of DSM-III as GAD.

2. Whether or not other benzodiazepines besides alprazolam, particularly if prescribed in higher than FDA-approved therapeutic dosages, will be helpful in patients suffering from PD with and without marked agoraphobia cannot be determined at this time. PD patients suffering from marked agoraphobia have so far not responded as well to older benzodiazepines prescribed in the usual ther-

apeutic dosages than to imipramine, phenelzine, or alprazolam. However, since studies frequently do not separate patients suffering from pure PD from those suffering from panic disorder with agoraphobia, the question is left unanswered whether the improvement registered in these studies was largely contributed by patients suffering from pure PD or patients suffering from more severe agoraphobia. It is hoped that the completed, as well as ongoing, multicenter Upjohn trials will provide important answers to this question.

3. If differences in antipanic/antiagoraphobic efficacy between alprazolam and other benzodiazepines should indeed exist, one may ask: Are these differences related to the fact that patients are better able to adjust to the sedative effects of alprazolam than to those of other benzodiazepines, or are they related to the triazolo-ring structure unique to alprazolam? Similar speculations may also be made to explain alprazolam's "antidepressive" properties (Feighner et al., 1983; Rickels et al., 1985). In fact, in a recently completed study by this research group (in preparation) alprazolam and imipramine produced equal degrees of improvement and significantly more improvement than placebo or diazepam in patients suffering from major depressive disorders.

4. If the original experience of the alprazolam research program, namely that alprazolam has to be given in relatively high daily dosages (6 to 10 mg in the Upjohn-supported studies and up to 15 mg in the authors' own experience in selected patients), should be confirmed, one certainly has cause for concern regarding treatment discontinuation, treatment which for PD with agoraphobia may last for at least 6 to 12 months. In fact, if abruptly stopped, seizures (Breier et al., 1984) or other severe withdrawal symptoms (Noyes et al., 1985) can be expected. Fortunately, at least in the authors' experience, most PD patients are not in need of such excessive daily dosages but respond well to only 2 to 4 mg/day of alprazolam. Higher daily dosages may be required, however, for patients suffering from marked agoraphobia. Research is presently under way by our research group to determine the safest and most convenient management of discontinuation from alprazolam treatment after prolonged use.

Among the many potential problems, just one should be mentioned here. Patients frequently experience panic attacks during alprazolam discontinuation which then is interpreted by patient and physician as a return of the original panic symptoms, while indeed they may represent for many patients a rebound phenomenon or withdrawal reaction. Needless to say, if other benzodiazepines are used in equipotent dosages for prolonged periods of time in the treatment of PD, similar problems to those possibly caused by alprazolam discontinuation can be expected.

5. The authors suggest that one may be dealing with several subgroups of PD patients. One group of patients either outlasts their initial panic attacks without treatment or will adjust to them in such a way that they cease to be a hindrance, such as, for example, sitting on the aisles in movie theaters or having to stand close to a door in a subway. A second group of patients suffering from panic attacks obtain relief with the usual dosages of various benzodiazepines and their panic attacks are aborted or prevented and thus little chance exists to develop secondary phobic avoidance behavior. For these two patient groups, GAD might be in many cases as appropriate a diagnosis as PD. Finally, there are those patients whose panic attacks do not go away on their own or do not respond to benzodiazepine treatment; these patients will with time either develop secondary avoidance behavior (agoraphobia) or hysterical and somatization behavior (Katon, 1984). It is probably this subgroup of PD patients, who also suffer from marked agoraphobia, who are in need of pharmacological intervention with such agents as imipramine, phenelzine, or alprazolam prescribed alone or in conjunction with various methods of behavior modification.

Conclusion

The authors suggest that the role of benzodiazepines for the treatment of panic disorder needs yet to be clarified. Good clinical evidence indicates that many patients who suffer from PD with or without agoraphobia respond to alprazolam therapy, particularly if alprazolam is prescribed in higher than FDA-approved therapeutic daily dosages. It has further been shown that patients suffering from agoraphobia and panic attacks do respond to imipramine and phenelzine. Evidence also exists, albeit based on less than the most rigorous research, that PD patients without marked agoraphobia respond well to nontriazolo benzodiazepines, such as diazepam, for example.

No answer has yet been provided to the question of whether or not benzodiazepines differ among each other in their potential to help patients suffering from PD with or without agoraphobia, when prescribed in equipotent dosages. And if differences should be found, are they related, for example, simply to the patients' ability to tolerate alprazolam's side effects, or are they related to its unique triazolo ring structure?

Much more research needs to be carried out to clarify the role of benzodiazepines for the treatment of panic disorder *with* and *without* agoraphobia. Various benzodiazepines have to be compared in equipotent dosages over similar periods of time in well-controlled studies. What is the minimum daily dosage necessary to produce desired results? Could it be that most PD patients respond to FDA-recommended therapeutic dosages and that only a limited group of severe agoraphobics may require excessive dosages not yet approved by the FDA?

Since some research has recently reported that imipramine also may possess antianxiety effects (Lipman et al., 1981), it may well be that the effect of phenelzine, a monoamine oxidase inhibitor (MAOI), and imipramine, a tricyclic, in PD may be similar to their effects in GAD when prescribed in appropriate dosages and for adequate periods of time (i.e., if patients could be persuaded not to drop out of treatment because of side effects). Thus we might learn in time that there are more similarities than dissimilarities between antidepressant, antianxiety, and antipanic agents.

In the meantime, it behooves the psychiatrist treating patients suffering from PD with or without agoraphobia to use the lowest daily medication dose which will produce desired clinical results and to treat the patients for the shortest time possible. A general guide might be that the more chronic and the more severe the panic disorder and the more intense the presence of secondary avoidance behavior and/or agoraphobia, the longer should be the duration of treatment and the higher the daily dosage. If patients have been on therapeutic or certainly if on higher than recommended therapeutic dosages of benzodiazepines for 6 to 12 months, drug discontinuation has to be conducted slowly and carefully, and physician and patient should be reminded that only a drug-free period of at least several weeks will allow for determining with some certainty whether the "reoccurrence of panic attacks" represents a return of original symptoms or a rebound phenomenon. Best results may well be obtained with a treatment regimen which combines the use of medication with some method of behavior modification.

Physostigmine in Patients With Alzheimer's Disease

Michael Davidson, M.D.,[1] Richard C. Mohs, Ph.D.,[1] Eric Hollander, M.D.,[1] Bonnie M. Davis, M.D.,[1] Theresa Ryan, M.S.,[1] Thomas B. Horvath, M.D.,[1] and Kenneth L. Davis, M.D.[1]

Postmortem examination of brain specimens from patients with clinical diagnosis of Alzheimer's disease (AD) repeatedly demonstrated neurotransmitter deficiencies in the neocortex. The most consistent evidence point towards a reduction in markers reflecting cholinergic activity (Davies, 1979; Perry et al., 1977, 1978). While other neurotransmitters like norepinephrine and somatostatin were found deficient, this was in addition to, and not instead of, the cholinergic deficiency (Adolfsson et al., 1979; Rossor et al., 1980). Furthermore, reduction in choline acetyltransferase (CAT) activity was reported in brain areas related to memory and learning and the deficit quantitatively correlates with severity of dementia (Perry et al., 1978). Additional support for the role of acetylcholine (ACh) in learning and memory, and implicitly in AD, comes from pharmacological studies.

Administration of cholinomimetics to young normal subjects was found to enhance encoding of new information beyond immediate memory (Davis et al., 1978). Conversely, administration of scopolamine, a centrally active anticholinergic, resulted in transient cognitive improvements phenomenologically similar to age-related memory dysfunctions (Drachman & Levitt, 1974). For all those reasons, enhancement of cholinergic neurotransmission in patients with AD would be expected to ameliorate some cognitive dysfunction.

Pharmacologic strategies employed in this attempt included administration of direct cholinergic receptor agonists; increasing ACh synthesis by precursor loading; and limiting ACh breakdown by inhibiting acetylcholinesterase (AChE). Clinical trials of cholinergic agonists have produced very mild improvements in symptoms of AD; however, these studies were seriously hampered by adverse effects. In spite of encouraging results in laboratory animals, the precursor loading strategy using lecithin and choline produced minimal or no improvements in patients with AD (Etienne, 1983).

Physostigmine, a competitive AChE inhibitor, has been used in at least nine clinical studies of patients with a clinical diagnosis of AD (Ashford et al., 1981; Caine, 1980; Caltagiorne et al., 1982; Kaye et al., 1982; Muramato et al., 1984; Peters & Levin, 1979; Smith & Swash, 1979; Sullivan et al., 1982; Thal et al., 1983). In contrast to the tonic effect of muscarinic agonist, physostigmine administration may better mimic the more phasic effect of endogenous ACh. Furthermore, physostigmine can be administered relatively safely, an important consideration in a target population with an often compromised cardiovascular system. This paper discusses our results of clinical trials with physostigmine in AD patients together with methodological implications relevant to this pharmacologic strategy.

---

[1] Department of Psychiatry, Bronx VA Medical Center, Bronx, NY 10468.

Patients meeting National Institute for Neurological and Communicative Disorders and Stroke (NINCDS) criteria for "probable AD" were included in the study (McKhann et al., 1984). The diagnosis of AD was supported by a clinical history demonstrating at least 1 year of progressive deterioration in cognition and other higher cortical functions; Dementia Rating Scale scores higher than 4; and a Memory and Information Test score of less than 10. Other tests used in the diagnostic process were the CAT scan, biochemical screening tests, thyroid function tests, serum B_{12} and folate levels, and neurological and psychiatric examinations. Particular care was taken to rule out patients whose dementia might be due to alcoholism, depression, or other neurological or medical conditions. To rule out patients with multi-infarct dementia, all patients were assigned a Hachinski Ischemic Score (Hachinski et al., 1975) and any patient with a score over 4 was excluded. All patients were free of psychoactive medications except those administered as part of these investigations, during and for at least 2 weeks prior to any study.

In order to establish the effect of physostigmine on cognitive symptoms of AD patients, the drug was initially administered intravenously. Previous animal and human studies demonstrated that intravenous physostigmine has a narrow therapeutic window. Doses slightly below this window produced no cognitive improvement while doses slightly exceeding the therapeutic window may in fact worsen performance on cognitive testing (Bartus, 1979; Davis et al., 1976). Therefore, an adequate test of physostigmine's efficacy requires a dose-finding phase in which a best dose is assigned to individual patients. Such a study design involves several testing sessions on the drug condition and only one testing session on placebo, thus increasing the likelihood of a drug effect to occur by chance.

In order to avoid this methodological flaw at the end of the dose-finding phase, a trial of the best physostigmine dose and a trial of placebo were repeated. Physostigmine (0.125 mg, 0.25 mg, and 0.5 mg) or saline placebo was randomly infused over 30 minutes. Starting 15 minutes into the infusion and ending 5 minutes after the end of the infusion, patients were given three trials on a visual recognition memory task. On each trial the patient was first presented with 12 words or pictures which were subsequently mixed with 12 additional items not previously shown to the patient. The 24 items were then presented, one at a time, and the patient was asked for each item whether or not it was one of the previously presented. Thirteen of the 16 patients included in the study showed a moderate transient improvement while receiving a dose of physostigmine and 3 patients performed best on placebo. A significant effect was demonstrated for the 13 "responders" included in the replication phase (F 1,11) $= 8.00$, $p<.02$), indicating that patients gave more correct responses while receiving physostigmine.

In spite of the theoretical importance of this finding, confirmed by others (Christie et al., 1981), its clinical applicability is limited by the short action of intravenous physostigmine. A meaningful evaluation of the drug's therapeutic potential in AD required a better and safer delivery route which would enable a comprehensive evaluation of this drug over an extended period of time. Such a comprehensive evaluation needs to assess cognitive and non-cognitive symptoms and possess the flexibility to include AD patients in different stages of this progressive disease. Alzheimer's Disease Rating Scale (ADRS) (Rosen et al., 1984) is such an assessment instrument and its reliability and validity are established. It is specifically designed to evaluate severity of symptoms in pharmacological studies. Cognition and language are assessed by task such as object naming, following commands, orientation, and constructional and ideational praxis. Non-cognitive behaviors are assessed by item such as depression, cooperation, psychotic symptoms, motor activity, and vegetative signs. The scale includes a broad range of tasks so that both very severe and mildly symptomatic patients can be evaluated. A higher score on the scale represents a more severe form of illness. Using this scale in conjunction with repeated oral administration of physostigmine provides a framework to study the more chronic effects of this treatment.

When this oral physostigmine trial was conceived, it was predicted that not all patients would benefit from the drug. The ability of oral physostigmine to improve AD systems depends on the drug's absorption, central penetrance, and the number of functioning cholinergic neurons still intact. It should be anticipated that in patients with extensive cholinergic cell loss or major abnormalities in other neurotransmitter systems, physostigmine would be unlikely to either increase neurotransmission or improve symptoms. Consequently, it is necessary to obtain a measure of physostigmine's biological effect in the central nervous system along with measures of drug-induced behavioral change. Cortisol secretion may be a potential indicator of physostigmine effect on cholinergic activity, as suggested by human and animal studies, demonstrating that cholinergic drugs increase and anticholinergics suppress cortisol nocturnal secretion (Davis et al., 1982; Hillhouse et al., 1975; Krieger & Krieger, 1967). Therefore, the effect of physostigmine on plasma cortisol levels was measured in concomitance with the cognitive effect of the drug.

Twelve AD patients were given oral physostigmine in a dose-finding/replication study. Physostigmine (0.5 mg, 1 mg, 1.5 mg, and 2 mg) or placebo was given every 2 hours for 3 to 4 days between 7 a.m. and 11 p.m. The ADRS was administered on the last day of each drug condition between 1:30 p.m. and 3:30 p.m. On the last night of drug and placebo condition in the replication phase, blood was drawn each half hour between 11 p.m. and noon the next day and assayed for cortisol. To ensure the drug effect on the early morning cortisol secretion, physostigmine or placebo were continued until 11 a.m. on the next morning following the sleep study. Eleven of 12 patients studied had lower (better) ADRS scores on a dose of physostigmine which were maintained in 7 patients during the replication phase. Only about one-third of patients showed a consistent and clinically evident improvement on physostigmine. However, it is encouraging to note that patients who improved during the replication phase also tended to show the greatest improvement during the dose-finding phase, and this improvement was generally achieved on the highest dose of physostigmine. Examination of plasma cortisol values revealed a strong linear relationship between percent increase in cortisol and symptoms improvement ($r\ (6) = .88,\ p < .02$), suggesting that physostigmine improved AD symptoms only to the extent that the drug has a central cholinomimetic activity. Similarly, a study by Thal et al. (1983) suggests that AD patients are benefitted by physostigmine only to the extent that this drug had a significant inhibitory effect on cerebrospinal fluid AChE.

Physostigmine-induced improvement in some AD patients reported here is in agreement with most (Muramoto et al., 1984; Sullivan et al., 1982; Thal et al., 1983), but not all reported studies (Ashford et al., 1981), with consistently more robust effect being noted. These heterogeneous results have to be interpreted in light of the problems inherent in pharmacological studies of AD and, in particular, pharmacological studies with putative cholinomimetics. The diagnosis of AD is inherently problematic without tissue verification. Misdiagnosed patients have other neurologic disorders or lack the characteristic histopathologic findings required for postmortem validation of AD (Liston & Rue, 1983; Nott & Fleminger, 1975; Ron et al., 1979). Even rigorous diagnostic criteria as described in this study have a 10% error rate. Hence, typical pharmacological trials with relatively small sample sizes are less likely to find statistically significant group means if they include an inevitable misdiagnosed patient. Nevertheless, a recent study reported a mean effect of physostigmine for the entire group (Beller et al., 1985).

In addition to the uncertainty of the antemortem diagnosis of AD and suggesting a complex pathophysiology for this disorder are postmortem biochemical findings of other neurotransmitter deficiencies along with the well-established cholinergic differences. Noradrenergic, serotonergic, and occasionally dopaminergic deficiencies were reported in patients with a clinical diagnosis of AD and postmortem presence of plaques, tangles, and reduced cholinergic activity (Adolfsson et al., 1979; Bondareff et al., 1982; Bowen et al., 1983; Rossor et al., 1984). If these neurotransmitters have a functional role in symptoms of AD, a pharmacological strategy restricted to cholinergic enhancement may not benefit AD patients with multiple neurotransmitter deficiencies. Future studies should include combined neurotransmitter replacement.

Obviously any pharmacological intervention that will aid AD patients must ultimately address the cholinergic deficit. However, the ability of physostigmine to enhance cholinergic activity is dependent on the amount of ACh made available to the synaptic cleft by viable cholinergic neurons. The presumed retrograde neuronal distinction occurring in the course of this disease and the limited overlapping innervation of cholinergic receptors may decrease the efficacy of physostigmine as the disease progresses (Coyle et al., 1983). This may also explain the heterogeneous effects produced by physostigmine in AD patients in different stages of this disease.

However imperfect the theoretical background for the use of physostigmine in AD is, issues related to this drug delivery must be addressed. Little is known about physostigmine pharmacokinetics or central nervous system (CNS) penetrance; nevertheless it is presumed that a constant and stable drug presence in the CNS would be desirable. Also, experience derived from pharmacological trials of physostigmine suggest that most AD patients benefit from higher doses of this drug. This has to be reconciled with the peripheral adverse effects of physostigmine and the difficulties involved in chronic administration of multiple drug doses to a demented population. Slow oral capsules, and subcutaneous and intrathecal devices are some of the alternatives presently under consideration.

Intracranial Drug Administration in Alzheimer's Disease

Robert E. Harbaugh, M.D.[1]

Introduction

During the last decade there has been an explosion of information regarding the neurochemical activity of the central nervous system (CNS). The identification of numerous neurotransmitter, neuromodulator, and neurohormone candidates, and the elucidation of their roles in normal and pathological brain function, have vastly expanded the possibilities for pharmacologic manipulation in the treatment of neurologic disease.

Clinical application of this neurochemical information has, however, been plagued by difficulties with drug delivery to the CNS. Long-standing problems in clinical neuropharmacology include adverse systemic effects of neuroactive drugs, peripheral metabolism or inactivation of drugs, difficulties with blood-brain barrier penetration, erratic drug absorption and binding by serum proteins, adverse effects at one level of the neuraxis to achieve therapeutic effects at another (e.g., sedation with narcotic analgesics), and problems with patient compliance. One can think of few neuroactive drugs where at least one of these problems is not clinically significant. In addition, a number of potentially therapeutic compounds may never reach clinical trials because of these problems.

With implantable drug infusion devices and stereotactic neurosurgical techniques, the technology is available today to circumvent all of the above difficulties. Direct infusion of drugs into the cerebrospinal fluid (CSF) bypasses the problems of systemic side effects, peripheral drug inactivation, poor drug absorption, serum protein binding, and blood-brain barrier penetration. Continuous or programmable drug infusion devices ensure patient compliance. Regional drug infusions can obviate adverse effects at other levels of the neuraxis and it may, in time, be possible to infuse minute quantities of drugs directly into circumscribed areas of the brain parenchyma, thereby achieving neuroanatomically precise pharmacologic manipulations of brain function.

The rationale behind drug delivery to the CNS by central infusion and selection criteria for drugs for infusion will be briefly discussed. Experience here with central drug infusion for patients with Alzheimer's disease (Harbaugh et al., 1984) will be used to illustrate the application of this technology in a clinical setting. Potential complications of this treatment approach will also be discussed.

Rationale Of Central Drug Infusion

By and large, intrathecal drug administration has not proven to be effective (Aird, 1984). Therefore, the first question to be addressed regarding central drug infusion is whether these drugs achieve adequate brain penetration. The answer to this question depends not only on the drug involved but also on the method of central drug administration.

Most clinical trials of central drug administration have employed single or intermittent bolus injections into the subarachnoid space or ventricular system. Of all the ways to deliver drugs to the CNS, this is probably the worst. Single bolus injections result in very high CSF drug concentrations and relatively limited parenchymal penetration (Blasberg et al., 1977; Lee et al., 1960). In addition, a single large bolus of drug is likely to be more toxic and less effective than more frequent, smaller doses (Bleyer et al., 1978). However, even with bolus administration, drugs will penetrate the parenchyma and, as CSF is cleared by bulk flow, diffuse back into the subarachnoid space (Blasberg et al., 1977). In situations where high drug concentrations in the CSF or immediately adjacent parenchyma

---

[1] Section of Neurosurgery, Dartmouth-Hitchcock Medical Center, Hanover, NH 03756.

are desired (carcinomatous meningitis, spinal anesthesia/analgesia, chemical rhizotomy), bolus injections are effective. However, if deeper diffusion into parenchyma is necessary, longer term infusion is preferable.

Intravascular administration of drugs which cross the blood-brain barrier shows a rapid onset of action due to the short circulation time and extensive vascular-CNS interface (Aird, 1984). However, drugs administered into the CSF require much longer for adequate diffusion into the parenchyma (Lee et al., 1960). As the duration of central drug administration increases, the depth of parenchymal penetration, even of large protein molecules, also increases (Brightman et al., 1969). Therefore, to adequately evaluate the effectiveness of central drug administration, infusions must be carried out over a prolonged time.

In addition to the duration of central drug infusion, the rate of infusion may be important. Rates of infusion rapid enough to elevate CSF pressure will result in increased CSF absorption and therefore increase drug elimination by bulk flow (Katzman et al., 1970).

The site of infusion within the central compartment may also be of significance. Drug penetration into the parenchyma appears to occur more readily through the ependymal than the pial surface (Rall, 1968), and drugs administered into the subarachnoid space may not enter the ventricular system (Yen et al., 1978). Therefore, intraventricular drug infusion is a more reasonable approach for achieving diffuse brain penetration than is lumbar intrathecal administration. Conversely, if one wishes to confine drug effects to the spinal cord with minimal effects at higher levels of the neuraxis, then intraspinal infusion may be beneficial (Coombs et al., 1983; Harbaugh et al., 1982). Thus, some relatively restricted neuropharmacologic effects can be achieved. Theoretically, with stereotactic cannula placement and very low flow-rate infusion devices, delivery of minute quantities of drugs to very circumscribed regions of brain parenchyma is possible.

When evaluating the effectiveness of central drug administration, the choice of drug is at least as important as the method of delivery. The ability of a drug to cross the blood-brain barrier is more likely to be detrimental than beneficial if the drug is given as a continuous central infusion. Drugs which readily cross brain capillaries can be rapidly cleared from the CNS when infused into the CSF (Blasberg et al., 1975). The use of such drugs may be valuable if high local concentrations in tissue adjacent to the subarachnoid space or ependyma are desired. However, if deeper parenchymal penetration is the goal, then lipid insoluble, polar molecules are better candidates for infusion (Blasberg et al., 1975).

When considering drugs for long-term central infusion, chemical and biological stability become important criteria. For continuous infusion via an implantable pump, the infused drug must be stable at body temperature for at least as long as the cycle time of the infusion pump. In addition, if widespread diffusion of active drug into parenchyma is desired, then the drug infused cannot be rapidly metabolized within the CNS or CSF. This last consideration may not apply to local intraparenchymal infusion where a steep concentration gradient of active drug could be beneficial.

Clinical Experience

Our clinical experience at Dartmouth (Coombs et al., 1983; Harbaugh et al., 1982, 1984) with implantable infusion devices for central drug administration may serve to illustrate some of the points raised above. The clinical studies referred to were approved by our institution's committee for the protection of human subjects and informed consent was obtained before instituting any experimental treatment trials.

The evidence for the cholinergic hypothesis of Alzheimer's disease has been extensively reviewed (Coyle et al., 1983) and need not be repeated here. If this cholinergic hypothesis is correct, then augmentation of brain cholinergic activity may ameliorate some of the symptoms in these patients. Previous attempts at increasing brain cholinergic activity by administration of acetylcholine precursors, cholinesterase inhibitors, or systemic cholinergic agonists had been attended by some of the difficulties with drug delivery to the brain which have previously been discussed. Intracranial cholinergic drug infusion in patients with Alzheimer's disease was started as a means of testing the validity of the cholinergic hypothesis and as an attempt at therapy for a devastating neurologic disease with no known treatment.

By delivering a muscarinic agonist into the ventricular system or cisterna magna, the problems of systemic drug inactivation, serum protein binding, and drug absorption are avoided. The use of an implantable continuous infusion pump permits long-term intracranial infusion of drug or placebo on an outpatient basis and avoids any problems of patient compliance. Pump flow rates range from 1 to 2 ml/day, an insignificant amount compared to normal daily CSF production. Because of small daily drug doses (0.05 to 0.7 mg), systemic side effects are not encountered.

Bethanechol chloride, a pure muscarinic agonist, was chosen for infusion. The drug is a polar, water-soluble molecule which is not degraded by cholinesterases and is stable in solution.

For patients with Alzheimer's disease, drug distribution to the hippocampi, locus ceruleus, reticular nucleus of the thalamus, and cerebral cortex was desired and, for the reasons described above, a drug which does not cross the blood-brain barrier when infused into the ventricular system was chosen.

Potential Complications of Central Drug Infusion

The potential advantages of central drug infusion have been discussed. There are, however, some potential disadvantages which require equal consideration. These include the operative risks of catheter placement and pump implantation, and the risk of increased neurotoxicity.

As for any neurosurgical procedure, the risks of catheter placement and pump implantation include anesthetic complications, hemorrhage, and infection. Although all these risks are low, there is probably an irreducible minimum, and some complications must be anticipated. Our personal experience here with pump implantation now includes about 40 patients who have had pumps implanted for various indications. We have encountered no significant anesthetic complications but have had one infectious and one hemorrhagic complication.

The risk of neurotoxicity with intracranial drug infusions must also be considered. Certainly, toxicity studies in animals are mandatory before considering intracranial or intraspinal infusion of drugs in patients. Although such toxicity studies decrease the risk of human neurotoxicity, some unexpected reactions to drug infusions in patients are likely to occur. We have now been infusing bethanechol chloride intracranially in patients with Alzheimer's disease for up to 20 months. One patient developed a reversible parkinsonian syndrome of rigidity and bradykinesia and another developed a reversible CSF inflammatory response which may or may not have been related to drug infusion (Harbaugh et al., 1984). Certainly, experience with more patients infused for longer periods of time will be necessary before any accurate figures on the risk of neurotoxicity are available. However, to date, drug infusions appear to be well tolerated.

The feasibility of intracranial and intraspinal administration of neurotransmitter analogues has been demonstrated (Coombs et al., 1983; Harbaugh et al., 1982, 1984). However, the value of these therapeutic endeavors over presently available therapy remains to be proven. We are conducting studies of the effect of intracranial bethanechol infusion on activities of daily living and neuropsychologic test scores in a double-blind, placebo-controlled crossover design. Preliminary studies showed family reports of decreased confusion, increased initiative, and improvements in activities of daily living during drug infusion but no subjective improvement in short-term memory was reported. A battery of short-term memory tests has also not shown a statistically significant difference between drug and placebo scores.

Almost certainly, the technique of central drug infusion for neurologic disease is more important than the outcome of any single therapeutic trial. Neurologic disorders in which abnormalities of neurotransmitter activity or availability are pathogenetically implicated and structural damage to the CNS is minimal, may prove to be the most fruitful areas for the application of this technique. Movement disorders, epilepsy, and functional and psychiatric disease are obvious possibilities. Only time and further investigation will tell if this new approach for drug delivery to the brain will come to naught or herald a new era in neuropharmacology and functional neurosurgery.

Acknowledgments: David W. Roberts, M.D., Charles M. Culver, M.D., Ph.D., Mark C. Johnson, Ph.D., and Teddi M. Reeder, B.S., R.N., have been instrumental in developing and carrying out the Alzheimer's disease studies.

The Cholinergic Hypothesis of Memory Dysfunction in Alzheimer's Disease—Revisited

Nunzio Pomara, M.D.,[1] and Michael Stanley, Ph.D.[2]

Of all the neurotransmitter deficits which have been reported in Alzheimer's disease (AD), by far the most extensive and consistent changes have involved the cholinergic system (Bartus et al., 1982; Davies & Maloney, 1976; Price et al., 1982; Rossor, 1982). Correlations between the severity of dementia before death, the density of senile plaques, and the reduction in the activity of choline acetyltransferase (CAT), a marker of presynaptic cholinergic neurons, strongly support the role of these cholinergic deficits in the pathophysiology of memory dysfunction (Perry et al., 1978). To date, no such relationships have been established between severity of dementia and any of the other neurotransmitter abnormalities which have also been described in this illness (Greenwald & Davis, 1983).

Another finding which has lent further support to the possible involvement of the cholinergic dysfunction in the pathophysiology of memory deficits observed in patients with AD has been the observation that the administration of agents such as scopolamine, which interfere with cholinergic transmission, produces memory deficits in normals. These deficits are qualitatively similar to those found in early AD (Drachman, 1977).

All of the foregoing observations, together with the precedent of alleviating motoric dysfunction in Parkinson's disease (PD) by means of dopaminergic agents, have provided a rationale for several AD treatments, i.e., cholinergic precursors (choline, lecithin) and indirect and direct muscarinic agonists (physostigmine, bethanechol chloride, RS-86).

In contrast to the successful therapeutic interventions that have been developed for the treatment of PD, by and large none of these cholinergically based therapeutic strategies has led to clinically useful improvements in AD (Mohs et al., 1985; Wettstein & Spiegel, 1984).

Several explanations have been offered for the poor therapeutic outcome which has been observed in these clinical trials. It has been suggested that:

1. CAT needs two substrates for acetylcholine synthesis, i.e., choline and acetyl coenzyme A. Therefore, if both substrates are depleted in AD, simply increasing choline by means of cholinergic precursors would not be sufficient to increase acetylcholine synthesis.
2. High-affinity uptake system for choline, acetylcholine synthesis, and release are all dependent on neuronal activity and, therefore, simply increasing choline would not be sufficient to effect these parameters.
3. The therapeutic action of physostigmine and other cholinesterase inhibitors might be limited by the failure of enough acetylcholine to be released pre-synaptically, by their narrow therapeutic window, by poor penetration into the central nervous system, and possibly by their action to cause a "feedback" inhibition of acetylcholine synthesis and release.
4. The use of exogenous direct muscarinic agonists also might have a very narrow therapeutic window which may be difficult to overcome.
5. Misdiagnosis of patients has diluted treatment effects.
6. Deficits in other neurotransmitters, e.g., somatostatin, serotonin, dopamine, or noradrenaline, also might contribute to the pathophysiology of cognitive dysfunction in patients with AD.

Even when dose has been carefully titrated to optimize response, or when problems of entry into the brain have been circumvented by direct administration of a cholinergic agonist into the cerebral ventricles, the therapeutic outcome remains poor (Harbaugh et al. 1984; Mohs et al., 1985).

The failure of cholinergic agonists in the treatment of AD is in marked contrast to the clinically relevant improvements in PD patients following treatment with dopaminergic agents, and calls into question some of the underlying assumptions regarding our understanding of the cholinergic system in AD.

Two tacit assumptions underlying treatments with cholinomimetics have been that the function of muscarinic receptors remains normal in AD and that a hypoactivity of the central cholinergic system is invariably associated with this disorder. It is our contention that the currently available data do not allow any definitive statement either about the status of muscarinic receptor function or about central cholinergic activity in AD.

Muscarinic Receptor Responsivity in AD

A specific aspect of cholinergic function that has been overlooked is that the presynaptic cholinergic deficits may account only in part for the cholinergic dysfunction seen in AD, and that alterations in the functional responsivity of the remaining muscarinic receptors (M_1 and M_2) also may contribute to the pathophysiology of AD. To the extent that cholinergic transmission is reliant on the functional integrity of both pre- and postsynaptic components, the elucidation of muscarinic response in AD is of particular importance.

Although no significant reductions in the number of muscarinic receptors have been noted in AD (Bowen, 1983; Davies & Verth, 1978), the failure of these studies to observe a difference may by itself reflect some atypical characteristics of the cholinergic system. In contrast to lesions of the noradrenergic, dopaminergic, and serotonergic neuronal systems, which have been shown to be associated with receptor and behavioral supersensitivity (Creese et al., 1978; DeMontigny et al., 1980), lesions of the cholinergic system have not been shown consistently to produce either an upregulation of muscarinic receptors or denervation supersensitivity (Bracco et al., 1982; London et al., 1984; McKinney & Coyle, 1982). The failure to observe evidence for denervation supersensitivity in these animal experiments does not exclude the possibility that muscarinic denervation supersensitivity could occur in AD.

The results of these animal experiments do not permit definitive statements to be made on the impact of presynaptic cholinergic neuronal loss on the functional status of postsynaptic muscarinic receptors. Although most studies do not report a significant reduction in the number of muscarinic receptors in AD, the failure of these studies to find changes merely may reflect the inability of quinuclidinyl benzylate (QNB) binding, as it has been commonly applied, to distinguish pre- and postsynaptic receptors. Thus in AD, the loss of presynaptic receptors might not result in net decreases in QNB as a result of concomitant increases in postsynaptic muscarinic receptors. As far back as 1978, Davies and Verth speculated on the possibility of denervation supersensitivity to reconcile their findings of normal muscarinic receptor concentrations in the context of some loss of muscarinic cholinoceptive receptors in AD.

Recently, more direct proof for compensatory increases in postsynaptic muscarinic receptors was provided by Nordberg and colleagues (1983). These investigators noted that the number of muscarinic receptors, as measured by QNB binding in the hippocampus of Alzheimer brains, was significantly and inversely correlated with CAT activity. This suggests that, as the ascending cholinergic input to the hippocampus was lost, there was a compensatory increase in the number of postsynaptic muscarinic receptors.

In a more recent study, Mash et al. (1985) reported a selective decrease of presynaptic, M_2, muscarinic receptors in the cerebral cortex of AD brains which was positively correlated with the reduction in CAT activity. They reported no change in the M_1 postsynaptic receptors. However, this group of investigators, unlike Nordberg et al. (1983), did not report on the relationship between CAT activity and M_1 receptors. Without data on the relationship between CAT activity and M_1 postsynaptic receptors, compensatory changes in the M_1 receptors might not be detected.

Recently developed techniques for measuring receptor number are believed to be more selective and capable of distinguishing pre-

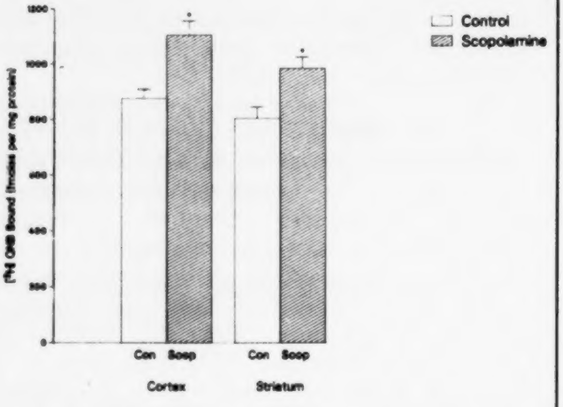

FIGURE 1. Chronic scopolamine increased the number of muscarinic receptors in rat brain as measured by QNB binding.

and postsynaptic muscarinic receptors. Nevertheless, these approaches may still not be adequate to differentiate receptors on more selectively damaged cholinergic pathways, i.e., those projecting from the nucleus basalis of Meynert, from receptors on intrinsic cortical cholinergic neurons and other non-cholinergic neuronal systems. Furthermore, the report of Mash and colleagues (1985) on the absence of upregulation of postsynaptic M_1 muscarinic receptors in AD does not address the larger question which concerns the functional status of the remaining muscarinic receptors.

Dissociations Between Muscarinic Receptor Number and Response

Changes in the functional response of muscarinic receptors are not necessarily reflected by alterations in static measures of receptor binding, i.e., number and affinity. This is illustrated in a number of animal experiments which have attempted to address this question directly.

Some studies report changes in the responsivity of muscarinic receptors that are in the direction anticipated from the change in number of muscarinic receptors as measured by QNB binding. For example, in a series of experiments conducted with rats by Lerer and colleagues (Lerer, 1985; Lerer & Sitaram, 1983), treatment with the muscarinic antagonist, scopolamine, led to an increase in the number of muscarinic receptors (Figure 1) which was accompanied by behavioral supersensitivity as measured by pilocarpine-induced catalepsy (Figure 2).

The same investigators (Lerer et al., 1983, 1984; Stanley & Lerer, 1985) found that the decrease in the number of muscarinic receptors that was produced by chronic electroconvulsive shock (ECS) (Figure 3) was accompanied by the anticipated decrease in responsivity (Figure 4).

However, this relationship between functional sensitivity and up- or down-regulation of corresponding receptors need not always be present. The same group of investigators demonstrated that while a single ECS caused no significant change in the number of QNB binding sites (Figure 5), it nevertheless induced a blunted cataleptic response to pilocarpine (Figure 6).

Data from a number of other investigators using a variety of experimental paradigms can be used to demonstrate similar dissociations between changes in receptor number and functional response (Lippa & Bartus, 1982; Marks et al., 1984; Pedigo et al., 1984).

Based on these animal data, the absence of a significant change in the number of muscarinic receptors in AD does not exclude the possibility of functional alterations in response. Both increases and decreases in functional response can occur in the absence of any change in the number of muscarinic receptors.

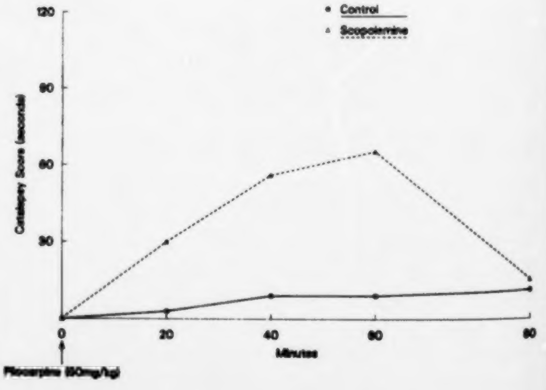

FIGURE 2. Chronic scopolamine increased pilocarpine induced catalepsy in accord with the increase in the number of muscarinic receptors.

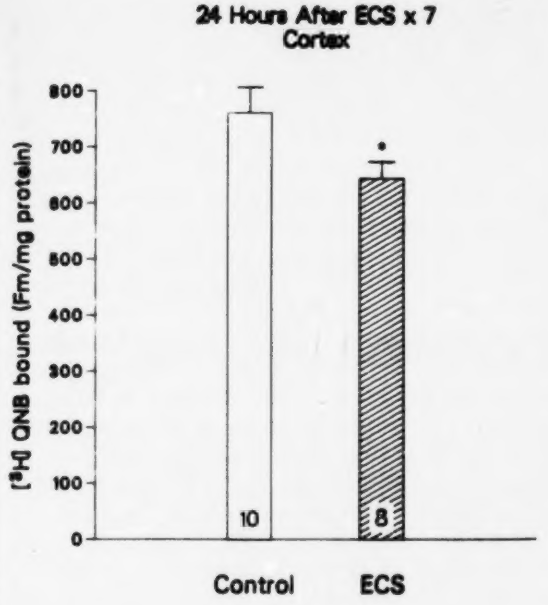

FIGURE 3. Chronic ECS decreased the number of muscarinic receptors in rat brain as measured by QNB binding.

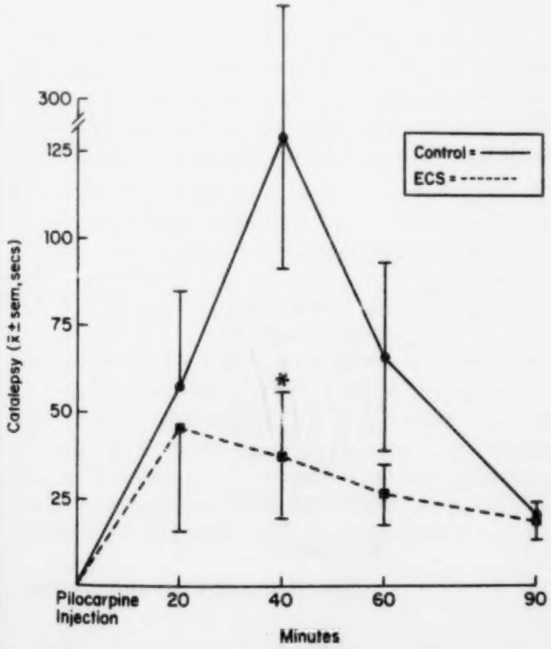

FIGURE 4. Chronic ECS decreased pilocarpine induced catalepsy in accord with the decrease in the number of muscarinic receptors.

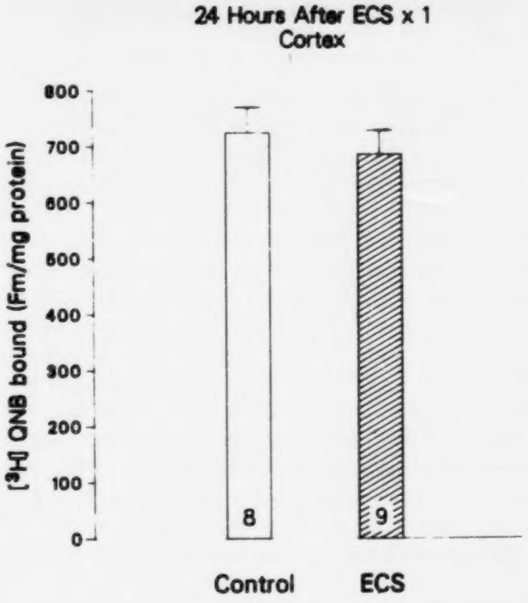

FIGURE 5. Acute ECS produced no significant change in the number of QNB binding sites.

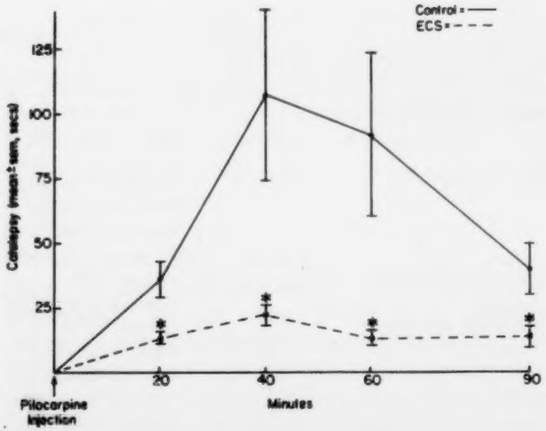

FIGURE 6. Acute ECS decreased pilocarpine induced catalepsy in rats even though muscarinic receptors, as measured by QNB binding, were not significantly altered.

Evidence for Cholinergic Hyperactivity in AD

In addition to a possible dissociation between changes in receptor number and function, there are a number of empirical findings in patients with AD which are more consistent with regional hyperactivity, rather than generalized hypoactivity of the cholinergic system. Patients with AD exhibit many abnormalities, e.g., hypercortisolemia, abnormal dexamethasone tests, depressive symptoms, and motor and memory dysfunction which also have been observed in major depression—a disorder for which a relative increase in cholinergic activity has been postulated (Janowsky et al., 1972, 1973). The Table presents some research findings which are consistent with cholinergic hyperactivity in AD.

Cortisol Hypersecretion

Cortisol hypersecretion, which has been reported in a significant number of patients with endogenous depression (Carroll et al., 1976, 1981; Fang et al., 1981; Sachar et al., 1973), also is found in a significant number of patients with Alzheimer-type dementia. There are at least three groups of investigators (Davis et al., 1983; Pomara et al., 1984; Raskind et al., 1982) that have reported high concentrations of plasma cortisol in individuals with AD. Davis et al. (1983) reported that the severity of dementia, as assessed by a number of rating scales, was correlated significantly with plasma cortisol concentration.

While a direct proof for the involvement of the cholinergic system in the development of hypothalamic-pituitary-adrenal axis hyperactivity in both depression and in AD is lacking, there are a number of observations that support such a role. Hypercortisolemia can be produced in both animals and man by administration of centrally acting cholinomimetics (Nurnberger et al., 1983; Pepper & Krieger, 1984). The administration of physostigmine, a centrally acting cholinesterase inhibitor, to normal individuals leads to the development of symptoms which mimic those found in depression. Additionally, physostigmine causes a reduction of manic symptoms in manic-depressive illness and an exacerbation of depressive symptoms in depressives (Davis et al., 1978; Janowsky et al., 1973; Risch et al., 1981). These findings suggest that central cholinergic activity may be increased in depression and may provide the basis for hypercortisolemia.

The only consistent neurochemical abnormality in AD which has been correlated with the clinical and neuropathological features of the disease has been the reduction in CAT activity. This has been interpreted as indica-

TABLE

Findings Consistent With Cholinergic Hyperactivity

	Alzheimer's Disease	Major Depression Study
Hypercortisolemia	Raskind et al., 1982 Davis et al., 1982 Pomara et al., 1984	Sachar et al., 1973 Carroll et al., 1976 Fang et al., 1981
Abnormal DSTs	Raskind et al., 1982 Davis et al., 1982 McKeith, 1984 Pomara et al., 1984	Carroll et al., 1976 Brown et al.,1979 Fang et al., 1981
Motoric Dysfunction	Pearce, 1974 Pomara et al., 1981	Wolff et al., 1985
Depressive Symptoms	Ziegler, 1954 Gustavson, 1975 Kendel, 1976 Roth, 1975 Epstein, 1976 Cawley, 1973	By definition
Cognitive and Memory Deficits	Reisberg, 1983	Weingartner et al., 1981
Dementia Syndrome	Reisberg, 1983	Folstein & McHugh, 1978 McAllister & Price, 1982

tive of a postulated decrease in central cholinergic activity. The finding of hypercortisolemia in AD patients is incompatible with the previously described animal and human studies in which more cortisol was released when central cholinergic activity increased. One would have predicted that the cholinergic deficiency in AD would have led to low cortisol levels. This contrasts with the increased incidence of hypercortisolemia reported in the AD patient population.

Abnormal Dexamethasone Suppression in AD Patients

Additional data that would be consistent with cholinergic hyperfunction are the numerous reports of abnormal dexamethasone suppression tests (DST) in individuals with Alzheimer-type dementia. At least four studies have reported significant increases in nonsuppression in patients with AD (Davis et al., 1983; McKeith, 1984; Pomara et al., 1984; Raskind et al., 1982). Further support for cholinergic hyperfunction as an underlying mechanism for dexamethasone non-suppression was provided by an experiment in which we induced an up-regulation of muscarinic receptors. This led to a significant degree of non-suppression which was not present in animals in whom muscarinic receptors were not up-regulated (Gershon et al., 1985).

A similar mechanism for abnormal dexamethasone responses in AD was suggested by the findings reported by Nordberg et al. (1983). They found a significant inverse correlation between CAT activity and the number of muscarinic receptors which suggested compensatory changes. Consistent with the interpretation of the findings of Nordberg et al.'s study, are the reports by Carroll et al. (1978) and Doerr and Berger (1983). These studies demonstrated that the usual suppression of cortisol after dexamethasone administration in normal subjects could be reversed by the administration of physostigmine.

Depressive Symptoms in AD

Also consistent with the hypothesis that major depression and AD may share some common pathophysiologic features which may be related to regional cholinergic hyperactivity, is the observation that a significant percentage of individuals with AD present with a depressive syndrome (Gustavson, 1975; Kendel, 1976; Ziegler, 1954). Similarly, many individuals with AD very often develop depressive symptoms in the course of their illness (Cawley, 1973; Epstein, 1976; Roth & Myers, 1975).

A primary depressive illness in the elderly can also lead to a dementia syndrome or to pseudodementia, a term which indicates its potential reversibility (Folstein & McHugh, 1978; McAllister & Price, 1982). These clinical entities are linked further by reports of cognitive and memory deficits in young depressives which are not qualitatively different from those found in early AD (Weingartner et al., 1981).

Motoric Dysfunction in AD and Depression

Motor activity is believed to be regulated in part by an interaction of dopaminergic and cholinergic neurons in the striatum. Extrapyramidal symptoms (EPS) in PD, a disorder associated with marked motor retardation, are believed to arise from an imbalance between dopaminergic and cholinergic tone in the striatum, i.e., the loss of dopaminergic function is believed to give rise to a relative increase in cholinergic tone. Supporting this hypothesis is the well-known observation that the administration of cholinergic antagonists leads to a diminution, whereas cholinomimetics cause an increase, in EPS.

A number of studies have reported EPS to be present in patients with AD (Pearce, 1974; Pomara et al., 1981). These observations support cholinergic hyperactivity in AD.

To our knowledge, there are no reports of EPS in depressive illness and there are no studies that have systematically evaluated the sensitivity of these patients to develop EPS in response to cholinomimetics. However, it is interesting to note that Wolff et al. (1985) recently found a significantly greater motor retardation in these patients during the depressive phase of their illness than during the euthymic or manic phases. Additionally, even during remission, individuals with affective illness showed lower motor activity than a control group.

Sleep EEG in Affective Illness and in AD

There are numerous studies that have implicated a role for the cholinergic system in the regulation of various components of sleep. Of particular interest is the finding that the induction of rapid-eye-movement (REM) sleep may be under partial cholinergic control (Sitaram & Gillin, 1979; Sitaram et al., 1984). This technique has been applied to study changes in muscarinic receptor sensitivity in individuals with affective illness. These individuals have been found to exhibit a shorter REM latency as compared to control subjects and a more rapid induction of REM sleep after administration of arecoline, a centrally acting muscarinic agonist (Jones et al., 1985; Sitaram et al., 1980, 1982).

Patients with Alzheimer-type dementia, as well as individuals with affective illness, also exhibit abnormalities in sleep architecture. On the other hand, when comparisons between the two disorders are made, they appear to be dissimilar with respect to baseline REM latency (Prinz et al., 1982). However, the important challenge tests using cholinergic agents such as arecoline will be needed to fully elucidate the extent to which these two illnesses are related.

Conclusion

The presynaptic cholinergic deficits that consistently have been observed in AD have been interpreted as indicative of a generalized cholinergic hypoactivity. However, there are a number of empirical data which have been reported in patients with AD which are best explained by regional cholinergic hyperactivity. The therapeutic strategies which have been applied in the treatment of AD, however, have been based exclusively on the underlying assumption of generalized cholinergic hypoactivity.

As we have pointed out in this review, there are a number of empirical findings about AD which may be better explained by cholinergic hyper- not hypoactivity. With this in mind, it may be useful to design treatment strategies that may explore the possibility of cholinergic hyperactivity as having a role in some of the behavioral symptoms observed in this illness.

However, one of the more basic but untested assumptions is that the remaining muscarinic receptors in AD when appropriately stimulated would result in a restoration of normal cholinergic function. To date, direct evidence in support of this contention is not available.

As we have recently reviewed elsewhere (Pomara & Stanley, in press), a presentation of receptor number in AD does not always serve as a reliable index of receptor response.

Ceruletide for Schizophrenia: A Review

Jeffrey A. Mattes, M.D.,[1] William Hom, M.D.,[1] and Joseph M. Rochford, M.D.

The majority of schizophrenics have residual symptoms, with functional and social impairment, despite an optimal regimen of neuroleptic medication. Additional treatment approaches, therefore, are needed. A compound recently reported to improve schizophrenics already on neuroleptics is ceruletide. Ceruletide, found in amphibians, is a decapeptide structurally nearly identical to the C-terminal amino acid sequence of cholecystokinin (CCK), a 33-amino acid polypeptide secreted by the duodenum to initiate contraction of the gall bladder during digestion (Morley, 1982).

As with other polypeptides (e.g., ACTH, vasopressin), CCK has been found to have central nervous system (CNS) effects apparently unrelated to its originally discovered hormonal effect. There is evidence that CCK is present in the brain (Beinfeld & Palkovits, 1981; Morley, 1982), acting as a neurotransmitter or neuromodulator (Snyder, 1980). Receptors for CCK have been found (Hays et al., 1982; Itoh et al., 1982; Saito et al., 1980). CCK in fact seems to be one of the most highly concentrated of the putative regulatory peptides in the brain (Noyer et al., 1980).

Relevant to schizophrenia, Hökfelt et al. (1980) discovered the coexistence of CCK and dopamine in mesolimbic, but not nigrostriatal, dopamine neurons. In addition, CCK has been reported to reduce dopamine turnover in the caudate nucleus and nucleus accumbens (Fuxe et al., 1980), to increase striatal dopamine release (Kovacs et al., 1981), to increase dopamine cell firing (Skirboll et al., 1981), to affect dopamine binding (Fuxe et al., 1981; Murphy & Schuster, 1982), and to modify dopamine receptor sensitivity (Hommer & Skirboll, 1983). Zetler (1983) found ceruletide to have neuroleptic-like activity in mice, Cohen et al. (1982) found that combining CCK-8 with haloperidol reduced signaled-avoidance behavior significantly more than either drug did alone, and van Ree et al. (1984) found ceruletide and other CCK analogues to be active in a number of behavioral test procedures in rats which predict antipsychotic activity; not all of these findings, however, have been consistently confirmed (Widerlov et al., 1983). Verbanck et al. (1984) recently reported reduced levels of CCK-8S in the cerebrospinal fluid of schizophrenics.

Moroji et al. (1982), in an open study, evaluated ceruletide in 20 schizophrenic patients refractory to neuroleptics. Results indicated

---

[1] Carrier Foundation, Belle Mead, NJ 08502.

improvement in both positive (e.g., hallucinations, delusions) and negative (e.g., withdrawal, blunted affect) symptoms after a single intramuscular (i.m.) injection of 0.3 or 0.6 mcg/kg to patients who were on stable dosages of neuroleptics for 3 weeks prior to the injection. The improvement was evident 2 hours after the dose, but peaked 1 week later. Moroji et al. found the higher dose, 0.6 mcg/kg, to be more beneficial than the lower. Side effects, slight abdominal pains, and borborygmus were minimal. Itoh et al. (1982), using a similar open design and comparable dosage, also reported benefit in 23 of 58 chronic schizophrenics; improvement was primarily in mood and spontaneity rather than in psychotic symptoms.

Nair and associates conducted two open trials of cholecystokinin (Nair et al., 1982, 1983a) and one open trial of the octapeptide CCK-8 (Bloom et al., 1983) in a total of 35 chronic schizophrenics, and also reported generally positive results. Nair et al. (1983b) subsequently conducted a placebo-controlled study of CCK in 17 schizophrenic inpatients, and reported positive effects on Brief Psychiatric Rating Scale (BPRS)-rated Anxiety-depression and Thought-disturbance 7 days after a single infusion, but the authors noted that the study was not truly double-blind since patients fairly consistently noted epigastric discomfort from the dose of CCK used. Peselow et al. (1983), in the second double-blind trial, using the octapeptide CCK-8, reported generally negative results. Nair et al. (1983b), however, found CCK-8 to show less striking results than CCK itself. Hommer et al. (1984), in a double-blind crossover study, found no benefit from ceruletide in 8 chronic schizophrenics, and no benefit from CCK-8 in 4 patients; however, the *N*s were small, and the use of a crossover design may have obscured drug-placebo differences, since the drug has been reported to act for up to 3 weeks (Moroji et al., 1982). Lostra et al. (1984), in another crossover study involving 9 drug-free schizophrenics (most other work has involved schizophrenics with residual symptoms stabilized on neuroleptics), also found no effect of ceruletide. In an additional double-blind study (Mattes et al., 1985), we administered two injections of ceruletide 0.6 mcg/kg or placebo to 17 chronic refractory schizophrenics and found no evidence of benefit.

Discussion

Five of six double-blind evaluations have not found beneficial effects of ceruletide in chronic schizophrenics. Given the previous positive reports from open studies, the samples, dosages, and evaluations used would appear to be more than adequate to demonstrate a positive effect; the most likely explanation for the discrepant results, therefore, is that positive reports reflected placebo responses.

There is still a question as to whether ceruletide crosses the blood-brain barrier (Cornford et al., 1978; Itoh et al., 1982). Analogues do affect sleep and appetite, but this may be through a peripheral mechanism, as some of these effects have been eliminated by vagotomy (Smith et al., 1981). The mechanisms of an apparent analgesic effect (Piazza et al., 1981) and of effects on dopamine receptors (Hommer & Skirboll, 1983) are unknown.

One would not expect that CCK analogues other than ceruletide would be more effective in schizophrenics; the CCK analogue found most in mammalian brains is the octapeptide CCK-8 (Cornford et al., 1978), but ceruletide has been found to be far more potent than CCK-8 in respect to CNS effects (Itoh et al., 1982). Also, ceruletide and CCK bind to the same receptors in all known receptor systems (Piazza et al., 1981).

Given the wide distribution and high concentration of CCK in the CNS, and its apparent interaction with dopamine and other neurotransmitters, it can be expected that CCK analogues and eventually CCK agonists and antagonists will continue to be of interest to psychiatrists. However, clinical relevance may depend on the development of analogues which more easily cross the blood brain barrier, or drugs structurally unrelated to CCK which nevertheless affect CCK receptors, synthesis, or release.

Clinical Evaluation of Ceruletide in Schizophrenia: A Multi-Institutional Cooperative Double-Blind Controlled Study

Hitoshi Itoh, M.D.,[1] Yasuo Shimazono, M.D.,[2] Yukio Kawakita, M.D.,[3] Yoshio Kudo, M.D.,[4] Yorio Satoh, M.D.,[5] and Ryo Takahashi, M.D.[6]

Introduction

Since cholecystokinin (CCK) is present at high concentrations not only in the tissues of intestines but also in the cerebrum and other parts of the brain and exerts a variety of behavioral pharmacologic actions, it has been presumed that these peptides might have some important effects upon mental function. Having found in animal experiments that CCK-8 has sedative and various other central actions, S. Itoh (1980) speculated that CCK-8 or its homologues might have antipsychotic effects.

On May 2, 1981, the Japan Economic Journal carried a surprising piece of news as a scoop with the heading: "Highly effective schizophrenia drug is found by ex-Hokkaido professor." According to the article, Moroji, a psychiatrist who was a member of Dr. Itoh's study group, observed a marked improvement of such psychic symptoms as emotional disturbance, autism, auditory hallucination, and delusion in 16 of the 20 patients with chronic schizophrenia receiving a CCK-like compound (Moroji et al., 1982a).

In that clinical study, caerulein diethylamine was administered intramuscularly (i.m.) at doses of as low as 0.3 to 0.6 μg/kg and the patients became refreshed in mood 2 hours after injection. The above-mentioned various psychic symptoms abated most conspicuously 1 to 2 weeks after start of treatment and the effects remained sustained over the ensuing several weeks in some of the cases, according to the newspaper.

Caerulein diethylamine (ceruletide) is a polypeptide isolated from the skin of tree frogs, *Hyla caerulea*, in Australia. It is structurally analogous to CCK-8 and endowed with physiological effects on the gastrointestinal tract and central nervous system (CNS) similar to those of CCK-8. A synthetic preparation has been commercially available as a drug for testing the biliary tract and pancreatic function.

A synthetic product of Pharmitalia Co., Ltd., was used in early clinical studies in Japan, including the initial clinical trial by Moroji et al. (1982a). Since the development of a highly pure synthetic preparation of ceruletide at the Research Laboratories of Shionogi Pharmaceutical Co., Ltd., in Japan a few months later, the Japanese product has become clinically used in this country.

Since 1982, many investigators in various countries have reported results of evaluation of the antipsychotic effects of CCK and its CCK-like peptides chiefly in schizophrenia (Hommer et al., 1984; Lotstra et al., 1984; Nair et al., 1982).

In another study of Moroji et al. (1982b), 12 patients with schizophrenia were treated with 40 μg of ceruletide injected at 2-week intervals, and a long-sustained clinical effect for 1 year was evident in 11 of these cases. Follow-up studies to confirm their findings have been made by many psychiatrists in Japan.

Results of open trials conducted as early phase II studies were diverse. According to a report by Kudo (1983), a significant clinical improvement was observed in 36.6% of 292 cases of schizophrenia treated, as assessed by

general improvement rating. It was inferred thereby that major indications for the drug would be chronic schizophrenics with manifest anxiety, blunted affect, and motor retardation.

Furthermore, Kudo (1983) conducted a double-blind, matched-pair, placebo-controlled study in patients with schizophrenia who were ceruletide responders, with the results reconfirming the efficacy of the drug.

In double-blind controlled trials with a crossover design performed by Y. Satoh, I. Hasue, and K. Miyakawa (personal communication, 1982) and by K. Sugano (personal communication, 1984), there was no significant difference in clinical effects between ceruletide and placebo.

Nakamura et al. (1984) performed a double-blind crossover trial in which ceruletide (0.6 µg/kg) and a placebo were administered on five consecutive occasions each without any other concomitant antipsychotic drug medication. They reported that the study yielded positive results, namely, general improvement rates of 67% on ceruletide and 33% on placebo and aggravation rates of 11 and 22%, respectively.

In an open trial of the drug conducted in 1981–1982 by Itoh, one of the present authors, clinical improvement was noted in 19 (34%) of the 58 patients with chronic schizophrenia receiving neuroleptic medications concomitantly (Itoh et al., 1982). This improvement rate is by no means high, and the numbers of patients studied were rather small in the above-described double-blind trials reported in Japan. Thus, the data obtained therein seemed to be insufficient for drawing any conclusion as to clinical usefulness of ceruletide.

In view of this, the authors set out a multi-institutional cooperative double-blind study as a nationwide organization.

Experimental Methods

Subjects

The subjects studied were 265 psychiatric inpatients at 28 hospitals with the diagnosis of schizophrenia according to DSM-III (Diagnostic and Statistical Manual—3rd. ed., 1980). Patients meeting the following two inclusion criteria were admitted to the trial preferentially, i.e., 1) those whose principal clinical picture was hallucinatory-delusional, abulic-apathetic, neurasthenic, or depressive state, and 2) the clinical course was chronic defective, periodic defective, transitional, or periodic complete abatement type.

FIGURE 1. **Administration and evaluation schedule.**

Drugs and Administration

Patients were randomly allocated, in a double-blind manner, to ceruletide or a placebo (vehicle).

As shown in Figure 1, either drug was given at 7-day intervals on four occasions by i.m. injection. Ceruletide was administered on a fixed-flexible dosage schedule; it was begun at an initial dose of 0.6 µg/kg and the dosage was individualized thereafter at the investigator's discretion according to symptom. The maximum dose was 0.8 µg/kg.

Other antipsychotic drugs that had previously been instituted were continued without modification of dosage throughout the study treatment.

Methods of Evaluation

Clinical Global Assessment. Each patient was subjected to assessments by General Improvement Rating at Weeks 1, 2, 3, 4, 6, and 8 of treatment. The overall ratings were made by the physician on a 4-point scale, in categories of "markedly improved," "improved," "unchanged," or "deteriorated." At completion of the study treatment, Final General Improvement Rating was made on the same scale as described above.

Both the overall degree of side effects and of accompanying symptoms as a whole were assessed at the termination of study medication using a 4-point scale as the Overall Safety Rating.

Furthermore, Global Usefulness Rating for ceruletide or placebo was performed on each patient with reference to the Final General Improvement Rating and Overall Safety Rating, on a 5-point scale, i.e. "markedly useful," "moderately useful," "slightly useful," "not useful," or "undesirable."

Assessment of Symptoms. Patients were evaluated for degree of symptoms at Weeks 0, 1, 2, 3, 4, 6, and 8 of the study, using the Brief Psychiatric Rating Scale (BPRS) as a rating instrument.

Results

Background Characteristics of the Patients

A total of 265 patients received study treatment in the trial, of whom 135 received ceruletide and 130 received placebo. These two groups were remarkably comparable in practically all of the patient background characteristics. Analysis of these pretreatment data did not reveal any statistically significant difference between the two treatment groups as to any of the items.

Dosage and Trial Outcome

Inter-group comparison showed no noticeable difference with respect to mean dose per day, number of doses given, or dosing pattern.

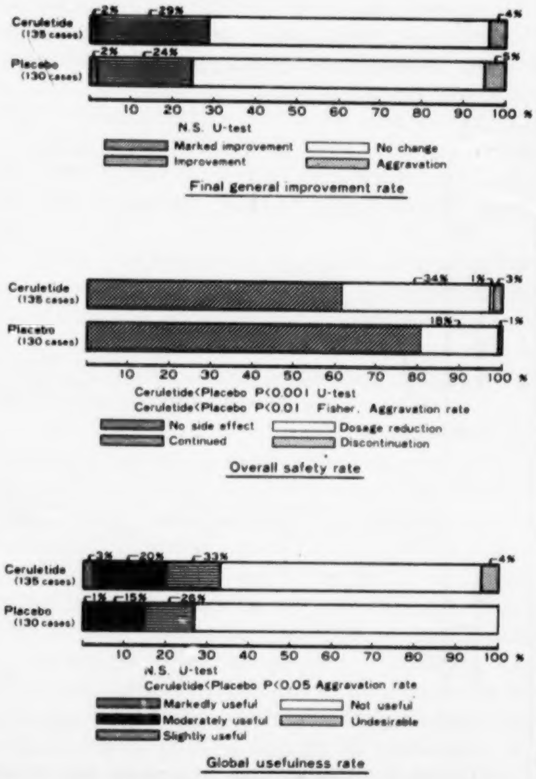
There were 7 patients who were withdrawn from the ceruletide therapy group and 1 patient from the placebo therapy group.

The Final Evaluation

The Final General Improvement Rating. As seen in Figure 2, there were only 3 markedly improved cases in each treatment group. The cumulative percentage of improved to markedly improved patients was 29% with ceruletide and 24% with placebo. Analysis of the data by Mann-Whitney U-test showed no statistically significant inter-group difference in this respect.

The Overall Safety Rating. As assessed by Overall Safety Rating, the incidence of untoward effects was 38% in the ceruletide therapy group and 19% in the placebo group. The former was significantly higher (Figure 2).

The Global Usefulness Rating. No significant inter-group difference could be seen in the overall therapeutic benefit assessment by Global Usefulness Rating by the investigator, when data were analyzed using the U-test (Figure 2).



Final general improvement rate

Overall safety rate

Global usefulness rate

FIGURE 2. Final evaluation.

The cumulative percentage of patients in whom the study medication was evaluated as "markedly useful" to "moderately useful" was 20% in the ceruletide therapy group and 15% in the placebo therapy group. Percent of cases in which the medication was "slightly useful" to "markedly useful" was 33 and 27%, respectively. Thus, there were no significant differences between the two treatment groups.

The General Improvement Rating at Each Week. The results of Weekly General Improvement Ratings during the study treatment are presented in Figure 3. No significant inter-group difference was observed at any week during the course of the 8-week treatment.

Transition of the Total Scores of the BPRS. As a method to assess the general improvement, transition of the total scores of the two drug groups was examined at each week. As shown in Figure 4, the total scores of the ceruletide therapy group were significantly improved at the end of both week 3 and 4 in comparison to the initial score ($p<0.05$, Wilcoxon test). However, there were no statistically significant differences between the two groups throughout the course of the trial by means of the total BPRS scores (Mann-Whitney U-test).

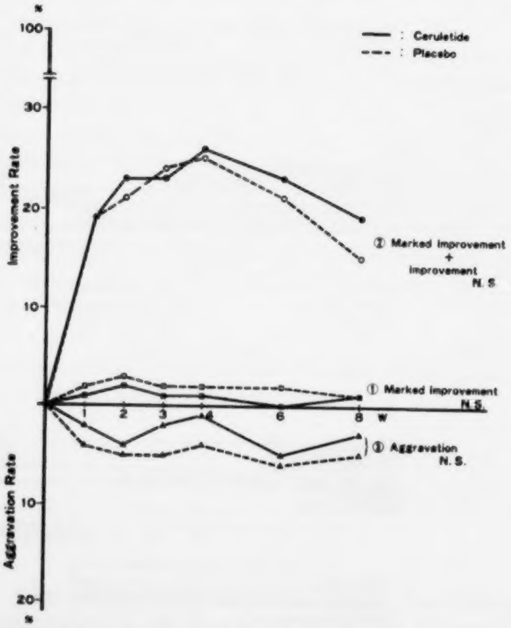


FIGURE 3. Comparison of general improvement rate (%) at each week.

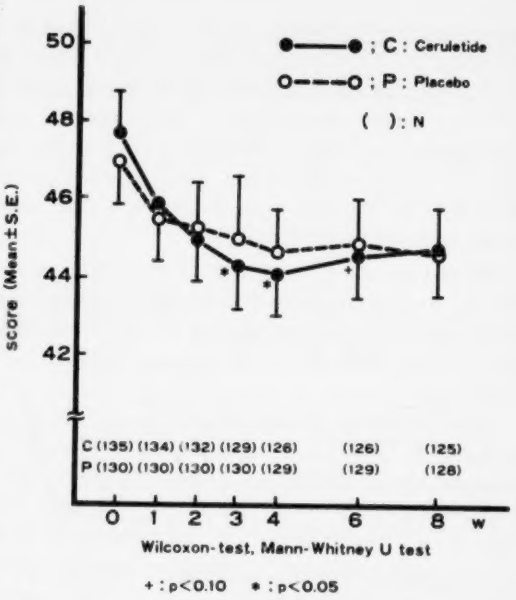

FIGURE 4. Comparison of changes of B.P.R.S. total score during the treatment.

Symptomatic Improvement Rating. From results of evaluation for degree of individual symptoms made at each week of treatment using the BPRS, improvement and aggravation rates were calculated by comparison with those at Week 0 and compared between the two treatment groups. The only symptom item for which ceruletide was significantly better was "Hostility" (Week 2, aggravation rate) whereas "Guilt feeling" was the only symptom item for which placebo was significantly superior (Week 1, aggravation rate).

Side Effects. The types and incidence of adverse effects encountered in the two treatment groups during the course of trial are shown in the Table.

Adverse reactions were significantly more frequent in the ceruletide therapy group ($p<0.001$, Fisher's test). The most common side effect was abdominal symptoms, occurring in 30 patients (41%) receiving ceruletide and in 9 patients (7%) receiving placebo; the incidence was significantly higher in the former ($p<0.001$, Fisher's test).

TABLE
Comparison of Main Side Effects

	Ceruletide (%)	Placebo (%)	Statist. analysis
Number of cases affected	49/135 (36)	21/130 (16)	$C<P^{***}$
Abdominal symptoms	41 (30)	14 (11)	$C<P^{***}$

C<P : Ceruletide inferior to Placebo
*** : $P<0.001$, ** : $P<0.01$, * : $P<0.05$, † : $P<0.10$
Fisher's test

As for individual side effects, nausea and stomachache were significantly more frequent among patients receiving ceruletide.

Discussion and Conclusion

Since the first discovery by Moroji et al. (1982a), there have been some dozen clinical reports concerning the antipsychotic effect of CCK or ceruletide in the treatment of schizophrenia. According to reports with positive results, the treatment produced improvement of both positive and negative symptoms in chronic schizophrenics refractory to treatment with previously introduced drugs.

Schizophrenia is an illness which is so diverse in disease type, disease picture, and clinical course that it seems more or less difficult to deal with it as a single disease entity.

It is unclear from the data documented in the literature what particular type or types, clinical course pattern, and disease state features of schizophrenia correspond to responders to CCK or CCK-like peptides.

In the clinical trial reported herein, chronic schizophrenics with disease state features and clinical course patterns corresponding to those in the cases described to have been improved by ceruletide in the reports of Moroji et al. (1982a,b), and subsequent reports of open trials in Japan were selected as the case material, as described above.

It can be noted from the data obtained in the present series that a) there was no significant difference in percentage of improved cases between the ceruletide group and the placebo group; and b) the improvement rates were remarkably low, as assessed by Final General Improvement Rating. Only 2% of patients showed marked clinical improvements, and the cumulative rate of improved-to-marked-improved cases was as low as 29%. These are the lowest figures that have ever been found in clinical trials of antipsychotic drugs.

Gastrointestinal symptoms were encountered as side effects with significantly greater frequency in the ceruletide therapy group; 4 patients receiving the drug complained of nausea and/or abdominal pain that led to withdrawal. These manifestations were attributable to the pharmacologic actions of ceruletide. The data indicated that the incidence and severity of these side effects increased with increasing therapeutic dosage and dosing frequency of ceruletide, an undesirable condition from the therapeutic viewpoint.

Thus, the results of the present multiclinical cooperative, double-blind controlled trial conducted in 265 patients with schizophrenia failed to provide evidence for clinical effects that would qualify ceruletide as a drug for the treatment of schizophrenia.

The numerous new findings reported by investigators in various countries concerning the interrelation of the central actions of CCK and the psychic function are of profound interest and of great importance. Among them are investigations aiming at elucidation of the underlying mechanisms of action on the hypothesis that CCK or ceruletide is endowed with antipsychotic effects on schizophrenia. Furthermore, as described in the reports of Moroji et al. (1982a,b) and in several other papers, it may be probable, in fact, that some patients with chronic schizophrenia respond with some alterations in symptoms when treated with CCK or ceruletide injections.

It is concluded from the present cooperative trials that no evidence has been found to substantiate usefulness of ceruletide as a drug for the treatment of schizophrenia.

Cholecystokinin: A Neuropeptide in the Treatment of Schizophrenia

Carol A. Tamminga, M.D.,[1] Robert L. Littman, M.D.,[1] and Larry D. Alphs, M.D.[1]

The distribution and functional activity of many peptidergic substances in the gastrointestinal system have been known for many years; more recently, a number of these have been found in the brain and are presumed to be neurally active. Cholecystokinin (CCK) is a member of this growing family of gut-brain peptides. It was first isolated from the gastrointestinal system in 1928 (Ivy & Oldberg, 1928), identified by its action on gall bladder smooth muscle, and sequenced as a 33-amino acid peptide in 1971 (Mutt & Jorpes, 1971). Not until 1975 was there evidence of a CCK-like substance in the brain (Dockray, 1976; Vanderhaeghen et al., 1975). Since that time various anatomic, biochemical, and behavioral studies have suggested a transmitter/modulator role for CCK in the brain (Beinfeld et al., 1981; Innes et al., 1979; Mueller et al., 1977; Rehfeld, 1978).

The predominant form of neuronal CCK is the carboxy-terminal octapeptide (CCK-8) (Mueller et al., 1977; Rehfeld, 1978). It derives from a polypeptide precursor synthesized in neuronal cell bodies, and modified by post-translational processing and cleavage during axonal transport down the neuraxis to form the octapeptide which remains stored in vesicles at the synapse (Eng et al., 1983; Schmitt et al., 1982). With depolarizing stimuli, CCK-8 is released from the nerve terminus to associate with specific receptors on postsynaptic neuronal surfaces. Inactivation of the peptidergic transmitter occurs by peptidase-mediated degradation rather than by reuptake into the presynaptic neuron. The initial catabolic step of CCK-8 degradation involves cleavage of the octapeptide into a C-terminal pentapeptide (Deschoht-Lanckman et al., 1981); subsequent steps produce the C-terminal di- and tri-peptide of CCK-8, which are relatively stable final products (Steardo et al., 1985). These intermediate and final catabolic products of CCK-8 are of interest because several of them show an affinity for the central CCK receptor and may have a functional interaction at the receptor (Knight et al., 1984). Thus, CCK, in addition to exerting an action itself at its receptor, may, after subsequent degeneration, continue to produce either agonist, partial agonist, or frank antagonist action at the same receptor through its peptide products.

CCK is known to produce characteristic hormonal effects in the body, which include stimulation of pancreatic enzyme secretion and gall bladder contraction. In addition, CCK has been associated with specific centrally mediated actions: appetite regulation, hyperglycemia, hypothermia, analgesia, central nervous system (CNS) depression, ptosis, catalepsy, and pituitary hormone modulation (Morley, 1982). CCK-8 produces what is described as satiety in rat, monkey, and man (Gibbs et al., 1973); it reduces conditioned avoidance responding in laboratory rodents (Cohen et al., in press), inhibits apomorphine-induced stereotypies (Zetler, 1983), and suppresses social behavior in mice (Crawley et al., 1981). These behavioral actions of CCK have been found after both central and systemic administration.

Interest in CCK for the treatment of schizophrenia was stimulated when CCK-8 was discovered to coexist with dopamine (DA) in certain mesencephalic neurons in the substantia nigra, area compacta, and in the ventral tegmental area (Hökfelt et al., 1980a). CCK-8 is found predominantly in those DA-containing neurons which project to the prefrontal and limbic cortex (Hökfelt et al., 1980b). Moreover, evidence suggests cholecystokinin may play a functional role in DA release (Markstein & Hökfelt, 1984), and in modulating neuronal metabolism in DA-dependent areas of cortex (Lucignani et al., 1984), even though this interaction remains difficult to consistently characterize

(Widerlöv et al., 1983). Since psychotic symptoms of schizophrenia improve after a reduction in DA-mediated transmission, neurally active substances which modulate activity of DA neurons hold promise as being active in the treatment of schizophrenia. Since currently available treatments for schizophrenia have considerable limitations, without other known pharmacologic strategies being effective in modifying psychosis (Tamminga, 1982), additional, improved therapeutic strategies for the treatment of this illness are eagerly being pursued.

This theoretical rationale for the use of CCK-8 in the treatment of schizophrenia is supported by a number of open clinical studies which have reported symptomatic improvement in schizophrenia with CCK-8 administration and with the administration of its more potent analogue caerulein (Moroji et al., 1982; Nair et al., 1982). However, since these early studies were not carried out in a blind design, and because a subsequent replication study was negative (Hommer et al., 1984), we carried out a series of studies with caerulein in schizophrenia to test for potential antipsychotic activity (Tamminga et al., in press).

In the first of these studies, 5 schizophrenic subjects, who were free from all medication for at least 1 month, were given a 0.3 μg/kg dose of caerulein, intramuscularly, in a double-blind design with placebo. Patients were evaluated prior to drug administration and at 2 hours, 4 hours, and 24 hours after the drug by Brief Psychiatric Rating Scale (BPRS) assessment for evidence of a change in psychotic symptoms, in DA-mediated endocrine parameters (prolactin and growth hormone), and in visual-evoked potential pattern, after either the caerulein or placebo. This study was intended to evaluate any immediate or delayed effects of a single dose of caerulein on psychosis, endocrine function, or visual-evoked potential. The results showed no effect of caerulein on the level of psychosis in these schizophrenic patients (Table 1), or on plasma levels of prolactin or growth hormone. In addition, caerulein did not alter the brain electroencephalogram (EEG) pattern of visual-evoked response. Despite these negative clinical indices, significant increases in plasma levels of caerulein were demonstrated after drug administration; levels achieved a maximum in 20 to 30 minutes and largely disappeared by 60 minutes (Table 2). We concluded from this experiment that caerulein administration at the previously tested dose levels, despite demonstrable blood levels, has no effect on psychosis of an immediate or delayed nature.

TABLE 1

Effect of Caerulein on Psychosis

Total Score	0	4 hr	24 hr
PL	53.7±15.5	49.5±14.2	52.7±15.2
CCK	53.3±24.2	54.5±26.3	53.0±25.2
Psychosis Score			
PL	9.5±6.7	8.8±5.6	10.3±5.2
CCK	9.5±6.7	9.7±6.1	9.0±7.4

The mean±SD of scores on BPRS: total score (Total) and psychosis subscale score (Psychosis) were collected after placebo (PL) and after 0.3 μg/kg caerulein (CCK), prior to drug administration (0), and at 4 hours (4 hr) and 24 hours (24 hr) following the drug. No significant differences were found between treatments or between treatments over time.

To evaluate the possibility that the previously administered dose levels were inadequate, increasing doses of caerulein from 0.3 μg/kg to 1.5 μg/kg were administered in a double-blind, placebo-controlled design to these same patients. The five drug-free schizophrenics received a 10-day course of daily medication: 5 days of active drug, and 5 days of placebo. The active drug was given in a rising dose sequence with single doses of placebo interspersed before, during, and after the caerulein sequence. Psychosis was evaluated at 0 time (prior to drug administration), at 4 hours, and 24 hours after caerulein and placebo administration. No patients showed an antipsychotic response to the peptide at any of the dose levels tested: 0.3 μg/kg, 0.6 μg/kg, 1.2 μg/kg, or 1.5 μg/kg. The

TABLE 2

Change In CCK-Li In Plasma After Caerulein Administration

	Minutes							
	0	5	10	15	20	30	45	60
Placebo	0	−1.7	−11.3	−9.0	1.0	−18	−7	3.7
		(8.6)	(10.1)	(11.5)	(1.0)	(15.9)	(10.8)	(17.8)
Caerulein	0	50.3	48.3	66	65.8	53.7	22.8	15.5
		(47.9)	(9.3)	(30.5)	(24.5)	(47.3)	(37.3)	(12.0)

Difference from basal values (mean SD) in CCK-like immunoreactivity (CCK-LI) (pg/ml plasma) after intramuscular administration of caerulein (0.3-0.6 μg/kg) or placebo to four human volunteers. Basal level of CCK-LI prior to placebo was 38.7±18.0, and prior to caerulein was 35.3±27.8.

upper dose of 1.5 μg/kg was limited by gastrointestinal side effects, chiefly mild pain and diarrhea.

Based on the suggestion from previous studies that a CCK-like drug would be active in neuroleptic-treated schizophrenic patients with a more chronic form of the illness, 6 chronically institutionalized patients, who were concurrently treated with stable doses of neuroleptic drugs, were given single doses of 0.3 μg/kg of caerulein or equivalent volumes of placebo in a parallel-group design. Their baseline psychosis level was established before they received the medication. Then, they were followed for psychosis change with the BPRS for 28 days after the single dose of drug administration. No patients who received the caerulein demonstrated improvement in their psychosis, nor did their response differ from those who received the placebo.

These studies provide no evidence for the hypothesis that systemic administration of caerulein, a potent CCK analogue, modifies schizophrenia, either by stimulating or reducing psychotic symptoms. Moreover, despite adequate caerulein drug levels in plasma, no definitive CNS effects of caerulein could be demonstrated; neither EEG patterns of visual-evoked potential changed nor plasma levels of prolactin were modified with caerulein, despite previous demonstration that intraventricular administration of CCK-8 elevates plasma prolactin in rats (Tanimoto et al., 1985).

While drawing a cautious conclusion because of the small number of patients tested, we would suggest that insufficient quantities of caerulein actually entered the CNS to produce a CCK-like effect. Thus, we would propose that the main hypothesis, namely that CCK-8 reduces psychosis through modifying DA-mediated neural transmission in the CNS, remains untested in schizophrenia at the present time.

We are pursuing the possibility of modifying CCK-8 levels in brain using other pharmacologic strategies, one being through inhibition of its degradation. CCK-8 is initially cleaved by a Mg^{++}-dependent metalloendopeptidase at the CCK^{3}/CCK^{4} bond (Steardo et al., in press). Blockade of this enzyme would be predicted to raise CNS levels of CCK-8 by inhibiting its breakdown and thereby producing a centrally mediated CCK agonist effect. Competitive and irreversible antagonists for this degradative enzyme are being synthesized. After establishing in vitro agonist effects of these compounds in laboratory animals, in vivo evidence of CCK-8 accumulation in the brain with systemic administration, and safety in human use, clinical evaluation in schizophrenia might be indicated. These kinds of alternate pharmacologic strategies will be necessary to test the hypotheses about the functional importance of CNS CCK systems in schizophrenia.

Introduction

We recently reported that fenfluramine produced significant symptomatic improvements in patients with the syndrome of autism (Ritvo et al., 1984). These included increased social awareness, eye contact and attention to school work, decreased hyperactivity and repetitive behaviors such as hand flapping and spinning, and improved sleep patterns. No serious side effects, adverse drug reactions, or disruptions in growth or weight gain occurred. Significant positive correlations were found between good clinical response and high baseline IQ ($r = 0.80$, $p = <.001$), between good clinical response and low baseline blood serotonin concentration ($r = 0.57$, $p = <.05$), and between low baseline IQ and high initial blood serotonin concentration ($r = 0.72$, $p = <.01$). However, due to the small number of subjects, these correlations were only considered suggestive. Interestingly, the onset of symptomatic improvements varied from a few days to 2 months and relapses showed similar wide variations after patients returned to placebo. Similar findings have been reported on other small groups of patients (August et al., 1985; Klykylo et al., in press; Stubbs et al., in press).

To extend these preliminary findings, we designed a two-part multicenter study to obtain data from a much larger number of autistic patients. This report contains the results of the first part of this study, an ABA design utilizing 81 patients from nine medical centers. Our results confirm the previous findings that fenfluramine is a safe and effective treatment for some autistic patients (August et al., 1985; Klykylo et al., in press; Ritvo et al., 1984; Stubbs et al., in press).

The A.H. Robins Company supplied fenfluramine (Pondimin®) and placebo tablets.

Methods

1. *Patient selection.* Eighty-one patients (80% boys, ages 33 months to 24 years; mean 8.8 years, mode 5.9 years) were selected at nine medical centers throughout the United States (*see* Appendix for list of multicenter participants). They represented the entire clinical spectrum of patients with the syndrome of autism, from the mute and totally dependent to those living semi-independently. Each unequivocally met the DSM-III, 299.0 (APA Diagnostic and Statistical Manual—3rd Ed., 1980), and National Society for Children and Adults with Autism (NSAC) (Ritvo & Freeman, 1978) criteria for autism according to clinicians at each medical center. Furthermore, each patient's history was reviewed with the principal investigator at UCLA (E.R.R.) who concurred that they had manifested pathognomic symptoms and delays prior to 30 months of age. All patients had been free of central nervous system active medication for at least 3 months before the study and were either attending special education classes or rehabilitation programs specifically designed for autistic persons. None had other specific diagnosable neurological or medical conditions except one girl who was subsequently identified in Portland, Oregon, as having Retts' syndrome (Stubbs et al., in press). Two had electroencephalograph abnormalities and one of these had a seizure when younger.

2. *Human subject protection procedures and FDA approval.* Each participating institution obtained Human Subject Protection Committee approval and informed consent agreements. Since fenfluramine is approved by the FDA only as an anorexia agent in adults, a new drug application (NDA) was obtained for use in children and for autism (for fenfluramine #17,085 and for the placebo #16,935).

3. *Experimental protocol.* The study began with a 2-week training period using a known placebo to accustom patients to taking tablets and to assure parental compliance (stage 1). The double-blind phase then began with all patients receiving placebo for 1 month (stage 2), followed by 4 months of drug treatment (stage 3), and 2 months of placebo (stage 4). One investigator at each center was aware of the placebo-drug schedule during the study but did not participate in dispensing medication or in clinical assessments. All patients received tablets twice a day throughout the study (0.75 mg/kg body weight for a total daily dose of 1.5 mg/kg body weight).

4. *Biomedical monitoring.* General medical histories and weights were recorded at monthly intervals throughout the study. Blood serotonin levels were obtained at the initial visits and between stages of the experiment.

5. *Parental reports.* Parental interviews were conducted monthly to monitor each child's clinical status and to detect possible side effects. Parents kept diaries documenting daily medication administration, patient behaviors, appetite changes, and weekly body weights. They were requested to weigh their children on the same scales, in similar clothing, and at the same time of the day.

6. *IQ tests.* Psychologists blind to the drug protocol administered tests selected according to each patient's baseline developmental level. Patients who initially were younger than 4 years or had IQ < 45 were given the Merrill-Palmer Preschool Performance Test (Stutsman, 1948) and the Cattell (1960) or Stanford-Binet Intelligence Scale. Patients initially older than 4 years or with IQ > 45 were given a Wechsler Intelligence Scale (1967, 1974, 1981) appropriate for their age. A verbal IQ score was assigned for each patient by using the verbal score for the Wechsler Scales, the Cattell score, or the Stanford-Binet scale. A performance scale for each patient was also assigned by using the performance score of the Wechsler Scales or the Merrill-Palmer Preschool Performance Test.

7. *Alpern-Boll Developmental Profile* (Alpern et al., 1980). This standardized parental interview scale was administered to patients for whom it was age appropriate. It consists of five developmental scales (academic, communication, physical development, self-help, and social development).

8. *Ritvo-Freeman Real-Life Rating Scale for Autism* (Freeman et al., in press). This scale consists of 47 behaviors grouped in five categories (motor, affect, language, sensory, and social). Behaviors are coded on a 4-point scale (0 = never, 1 = rarely, 2 = frequently, and

3 = almost always). It was administered by raters blind to the drug protocol, who observed the patients for 45 minutes.

9. *Principal investigators' classification of strong, moderate, and nonresponders.* One month after each center completed its protocol the principal investigator was asked to list any patients in whom "strong clinical improvements were noted by themselves and the patients' parents and teachers." These were labeled "strong responders." Two weeks later each principal investigator was again contacted and asked to list patients who "they and the patients' parents and teachers agreed showed absolutely no changes." These were labeled "nonresponders." Strong responders, nonresponders, and moderate responders (defined as those not placed in one of the other two categories by the principal investigators) were then grouped for correlation analyses.

10. *Statistical analysis.* Mean scores for all patients at each visit were used in the statistical analyses. The statistical procedures for the Alpern-Boll Developmental Profile, IQ, and Ritvo-Freeman Real-Life Rating Scale were repeated-measures analyses of variance, with individual comparison of means using the Duncan multiple-range test. Program was procedure GLM, Statistical Analysis System (Ray, 1982). Serotonin blood levels and blood platelet counts were analyzed by percent changes from baselines.

Results

1. *Patient compliance.* Three patients were withdrawn during the course of the study (in one case the parents moved; in two cases parents complained of irritability, anorexia, weight loss, and insomnia). Despite the blind nature of the study, the majority of parents observed symptomatic improvements during the medication phase and a return of pathologic behaviors after the blind crossover back to placebo. Some wished to withdraw their child from the study and obtain active medication from their personal physicians. However, all were persuaded to continue through the study before again medicating their children.

2. *Parental reports.* The beneficial effects most often reported by parents were 1) decreased restlessness and hyperactivity; 2) decreased repetitive behaviors such as hand flapping, jumping, self-injury, and spinning; 3) increased social responsiveness and eye contact ("more tuned in"); 4) increased attention span and participation in school programs; and 5) improved speech and nonverbal communication. After the blind crossover back to placebo, the order of symptom return reported was similar. Hyperactivity and repetitive behaviors reappeared first, then withdrawal and social inappropriateness and, lastly, cognitive and communication skills decreased to pretreatment levels. Great variability in the time of onset of improvements and remissions was reported.

3. *Side effects.* No serious adverse reactions occurred. Lethargy and irritability were the most frequent side effects reported. The side effects observed and their incidences at all the centers are being systematically studied and will be reported upon separately (George Realmuto, M.D., personal communication) as are those at one center (Piggott et al., in press).

4. *Blood serotonin concentrations and platelet counts.* Blood serotonin concentrations were available on 62 of the 81 patients (77%). Since assays were conducted in different laboratories (Yuwiler et al., 1970), percent changes from baselines were used for statistical analyses. Average blood serotonin concentrations fell 46% from baseline after 2 months on drug, 57% from baseline after 4 months on drug, and rebounded to 5% over baseline 2 months after drug was replaced by placebo. These changes on drug were highly significant ($p = <.0001$). Platelet counts were available on 44 patients of the 81 total (54%). Percent changes from baseline were again used for analysis. The average of all counts fell 5% from baseline after 2 and 4 months on drug. These decreases approached significance ($p = <.0867$). Inspection of the data reveals that changes in serotonin concentrations and platelet counts were quite consistent across patients. Thus it appears that the dosage selected (1.5 mg/kg body weight/day) uniformly decreases serotonin concentrations approximately 50% regardless of the initial blood levels (*see* Figure 1 and Table 1).

5. *Appetite and weight changes.* Anorexia occurred initially in 16 patients (20%) with remission in all but 2 patients after 4 weeks. In these 2 cases, food prompting and supplements were sufficient to prevent weight loss.

6. *Wechsler Intelligence, Cattell, and Stanford-Binet Scales and the Merrill-Palmer Preschool Performance Test.* Data on these are shown in Table 1. Significant differences occurred between baseline and medication periods as indicated.

7. *Ritvo-Freeman Real-Life Rating Scale for Autism.* The mean values of the overall, motor, social, and sensory scales showed significant improvements between baseline and drug periods (*see* Figure 2 and Table 1). The affect and language scales trended in the direction of improvement but mean changes did not reach significant levels.

8. *The Alpern-Boll Developmental Profile.* The mean values for the communication, self-help, and overall scales showed significant improvement between the baseline and drug periods (*see* Figure 3 and Table 1). The academic age, social, physical development, and IQ scales trended in the direction of improvement but did not reach significant levels.

9. *Principal investigators' classification of strong, moderate, and non-responders.* The distribution (number and percent) of all 81 patients by center and sex is shown in Table 2. Twice as many patients were classified strong responders as nonresponders (33% vs. 15%). The percentage of strong, moderate, and nonresponders at various centers ranged from 0% to 100%, indicating wide variability within and among centers. The combined total of strong and moderate responders was far in excess of just nonresponders (85% to 15%), indicating that a consistent overall favorable clinical impression was created. Sex is not correlated with response. The sex distribution in the 81 patients (4:1) is similar within the principal response classifications (86% of males and 81% of females classified as strong and moderate responders vs. 14% males and 19% females as nonresponders). Within the strong responder category alone there was a nonsignificant higher percentage

of males (37% of all males vs. 19% of all females).

10. *Correlations among baseline serotonin, IQ, behaviors, and clinical response.* The distribution by baseline laboratory and clinical data are shown in Table 3. Age is not correlated with response category, the means being only 13 months apart and the ranges showing great overlap. Baseline serotonin concentrations show a significant inverse correlation with clinical response categories, being lowest in the 11 strong responders measured (mean = .250), next higher in the 20 moderate responders measured (mean = .280), and highest in the 4 nonresponders measured (mean = .330) ($r = -.35$, $p < .05$). Verbal IQ and Performance IQ, Real Life Rating Scale, and Alpern-Boll Scale scores did not show significant correlations with any of the clinical response categories. Significant inverse correlations were also found between baseline serotonin concentrations and performance IQ ($r = -.57$, $p < .0025$) (*see* Table 3).

Discussion

The results indicate that fenfluramine is a safe and effective treatment for some autistic children and young adults, thus confirming earlier reports (August et al., 1985; Freeman et al., 1985; Geller et al., 1982; Klykylo et al., in press; Ritvo et al., 1983, 1984 Stubbs et al., in press). During the 4 months we administered it to children, only the same side effects observed in adults were noted. Any longer range effects will have to be studied separately. However, our prior report of administration for 12 months (Ritvo et al., 1984) and dozens of autistic patients we have learned about who have been on the medication for over 3 years indicate that at least in some children it can be well tolerated over these extended periods. Our anecdotal information also indicates that irritability, lethargy, anorexia, and other mild side effects usually last only during the first month of administration and can be eliminated by reducing the dosage. Although only a small percentage of patients experienced any side effects (Piggott et al., in press), certainly all parents should be informed of their potential appearance.

It is important to note that fenfluramine produced significant symptomatic improvements on both professionally administered scales (Ritvo-Freeman Real Life Rating Scale and the intelligence scales) as well as on the parent reported scales (Alpern-Boll). The improvements noted in the study of 81 patients were consistent with previous smaller sample studies in both the type and timing of onset after treatment began, and the return of symptoms after switching back to placebo.

This confirmation is particularly noteworthy, since the experimental design we utilized does not allow for assessing treatment order effect. However, such an effect should not confound the results of a study of autistic patients whose clinical courses are known to be stable over the span encompassed by this study (8 months) (Freeman et al., 1985). Nevertheless, a second experiment utilizing a design which mitigates treatment order effects is under way on an additional 99 patients at 14 medical centers.

IQ test scores showed slight but significant increases during the drug phase as was observed in our first two cases (Geller et al., 1982). The improvement in verbal scale scores probably reflects improved concentration and better relating to the examiner. The improved performance scale scores may have been due to these factors, combined with practice effects, as we have previously discussed (Ritvo et al., 1984).

The correlations that were found between baseline serotonin concentrations, IQ, and clinical response are consistent with earlier reports (Ritvo et al., 1984) and warrant further exploration.

TABLE 3

Principal Investigators' Classification of Clinical Responders and the Distribution of Baseline Measures

	Strong Responders	Moderate Responders	Non Responders

*Significant correlation ($r = -.57$, $p < .0025$) between baseline serotonin and performance IQ.

**Significant correlation ($r = .35$, $p < .05$) between response and baseline serotonin.

Several principal investigators reported their impressions that the medication produced differential effects in certain patients, depending upon their baseline verbal IQs. The clinical consensus was that patients with initially high verbal IQs (70 or higher) who responded showed mainly increased appropriate social responsiveness, lengthened attention spans, better concentration to cognitive tasks, and improved social conversation. They also showed, but to a lesser degree, decreased hyperactivity and repetitive behaviors. In contrast, patients with initially low IQs (50 or less) showed primarily decreased hyperactivity, improved sleep patterns, newfound ability to interrupt repetitive behaviors with appropriate training ("We had tried to get him to stop arm flapping before but it never worked"), and were "more tuned in."

The present results shed no light on such important issues as the method of action of fenfluramine or dose-response relationships. Hopefully, these and other relevant clinical and neurobiochemical issues will become of sufficient interest to be explored now that the efficacy and safety of fenfluramine as a treatment for some autistic patients has been more firmly established. Also remaining is the fascinating task of learning how to predict responders in advance, thus obviating the need for prolonged clinical trials of up to 8 months (Ritvo et al., 1984).

Short-Term Efficacy and Safety of Fenfluramine in Hospitalized Preschool-Age Autistic Children: An Open Study[1]

Magda Campbell, M.D.,[2] Stephen I. Deutsch, M.D., Ph.D.,[2] Richard Perry, M.D.,[2] Barbara B. Wolsky, C.S.W.,[2] and Michael Palij, Ph.D.[3]

Introduction

Ritvo and associates (1983) reported encouraging results associated with administration of fenfluramine over a period of 4 months in 14 autistic subjects; decreases of certain symptoms and increases in IQ scores, with only a few side effects, were rated.

Structurally, fenfluramine is similar to amphetamine, though their mechanisms of action differ. Fenfluramine is a potent antiserotonergic drug (Costa et al., 1971). Some reports suggest that fenfluramine is a mild antidopaminergic drug with sedative or tranquilizing properties (Alphin et al., 1964; Franko et al., 1964; Jori et al., 1974), while others indicate that stimulating effects are dose dependent (Riley et al., 1969).

It has been demonstrated that about one-third of autistic children show elevated serotonin levels in blood, as compared to normal controls; this elevation of serotonin was found in those autistic children who were more retarded and who showed more florid symptomatology (Campbell et al., 1975). In the studies of Ritvo and his associates (1983, 1984), there was a marked decrease of serotonin levels following treatment with fenfluramine.

New and potentially therapeutically effective drugs, which are devoid of long-term untoward effects, are sought for the treatment of autistic children. D- and L-Amphetamine, dopamine agonists, had untoward effects in this population which often outweighed therapeutic effects (Campbell et al., 1972, 1976). Haloperidol, a potent antidopaminergic drug, was found to decrease significantly behavioral symptoms and to facilitate learning in the laboratory, in two large samples of autistic children, when administered under double-blind and placebo-controlled conditions at doses ranging from 0.5 to 4.0 mg/day (Anderson et al., 1984; Campbell et al., 1978). At these doses, haloperidol was a safe drug when given over a period of up to 3 months cumulatively. However, in a prospective study, when given over a longer period of time to 58 children, 22% developed tardive or withdrawal dyskinesias (Perry et al., 1985). There is no agreement about the therapeutic efficacy of L-dopa (Campbell et al., 1976; Ritvo et al., 1971), a drug which reduces serotonin levels.

The 14 subjects who participated in the study of Ritvo et al. (1983) were all outpatients exposed to a variety of educational programs and heterogeneous in regard to chronological age (3 to 18 years).

We wished to administer fenfluramine in an open fashion under close clinical and laboratory monitoring to a small sample of carefully diagnosed inpatients, with a relatively narrow age range.

Method

Subjects

Ten children, 7 males and 3 females, ages 3 to 5.75 years (mean, 4.15), participated in this pilot study. They were all inpatients in Bellevue Hospital, Psychiatric Division, Chil-

dren's Inpatient Service and all met the DSM-III (1980) criteria for Infantile Autism, Full Syndrome, as determined by at least 2 board-certified child psychiatrists independently. Following admission, baseline evaluations were performed: these included complete medical diagnostic workup as well as psychiatric observation; psychological, neurological, pediatric, hearing, and speech evaluations; and laboratory studies. Children with a known cause for autism were excluded from the study. Two children had seizure disorder (grand mal).

All children were withdrawn, displayed stereotypies, and had very short attention spans. In addition, 6 children had temper tantrums; 8 were very irritable and were screaming; 8 were hyperactive and, in 3 of these 8, hyperactivity alternated with hypoactivity. One child was exclusively hypoactive. Eight children were aggressive and, in 4 of these, aggression was also directed against self. In 2 children, self-injurious behavior resulted in prominent frontal bossing due to chronic severe head banging. Four children had insomnia. The children's intellectual functioning ranged from mildly to profoundly retarded.

Procedures

All children were free of psychoactive drugs for at least 2 weeks prior to the study.*

Ratings were done at fixed intervals, twice during the placebo baseline and during treatment, independently, by two child psychiatrists. Ratings were videotaped. The following rating scales were used: the Children's Psychiatric Rating Scale (CPRS), Clinical Global Impressions (CGI), and Abnormal Involuntary Movements Scale (AIMS) (*Psychopharmacology Bulletin*, 1985); the Simpson Abbreviated Dyskinesia Rating Scale (Simpson et al., 1979); and the Fenfluramine Untoward Effects Checklist.

Electrocardiogram (ECG) and laboratory studies (urinalysis, complete blood count, differential, serum glutamic oxaloacetic transaminase, serum glutamic pyruvic transaminase, lactic dehydrogenase, creatine phosphokinase, alkaline phosphatase, and electrolytes) were also done during the baseline period and at the end of each 4-week treatment period. Blood pressure and heart rate were taken daily, and weight weekly, at fixed times, adhering to a protocol.

Fenfluramine and identical matching placebo tablets were supplied by A.H. Robins Company. Following a placebo baseline period,** fenfluramine was started at a dose of 10 mg/day, in two divided doses, and increments occurred gradually at fixed intervals. Dosage was regulated individually, until positive or untoward effects were observed. Dosage was reduced when untoward effects emerged.

Results

Dosage

Optimal doses for the 10 children ranged from 15 to 30 mg/day or 1.093 to 1.787 mg/kg/day (mean, 1.413). The maximum dose explored, in two children was 60 mg/day (3.625 mg/kg/day).

Untoward Effects

The untoward effects necessitating dosage reduction consisted of drowsiness and lethargy ($N=9$), including falling asleep 4 1/2 hours after the administration of an 8 a.m. dose, loss of weight ($N=7$), excessive and uncontrollable irritability ($N=6$), body "rigidity," tension, and fidgetiness ($N=1$), sadness ($N=2$), increased aggressiveness against self or others ($N=2$), insomnia ($N=1$), increased withdrawal ($N=1$), and increase of stereotypies ($N=1$). These untoward effects occurred above optimal doses or during dosage regulation, on 1.23 to 3.625 mg/kg/day of fenfluramine. There were no untoward effects at optimal doses: the exception was a 46-

---

*The exception were two children with seizure disorder: one was receiving Tegretol, and the other Dilantin, throughout the study.

**Exception were two children who were placed as an emergency without placebo baseline on fenfluramine because of their extremely severe irritability, insomnia, or self-mutilating behavior with temper tantrums.

month-old boy, who showed only slight improvement on fenfluramine (1.787 mg/kg). As indicated above, 7 of the 10 children lost weight (from 0.02 to 1.70 kg) at the end of 1 month of fenfluramine administration. At the end of the second month, all but one* gained weight (from 0.23 to 0.91 kg). One child gained weight during the first month of fenfluramine administration (1.68 kg), and lost 1.11 kg at the end of second month. During the entire period of fenfluramine administration, only two children lost weight. No child developed dystonic reactions or dyskinesias during this study.

Laboratory Studies

Blood pressure and pulse rate remained essentially the same throughout the study; there was no change in ECG and in laboratory studies.

Rating Scales

Children's Psychiatric Rating Scale (CPRS). Of the first 28 items, only 14 were analyzed because the remaining 14 are usually rated as absent in autistic children. Although CPRS ratings were taken at four different times, that is, two baseline and one at 4 weeks on drug and 8 weeks on drug, the measures taken at 8 weeks on drug are not included. This was done because only five subjects had complete data for the four occasions, in contrast to the eight subjects for the three times listed in Table 1. Obviously, the sample with the larger number provides for more powerful statistical tests as well as better representation of the population of subjects.

The values reported in the fifth column of Table 1, labeled ANOVA F represents the F statistic and significance level from a one-way repeated measure (analysis of variance) for the three occasions of measurement. Five of the items (i.e., items 3, 4, 8, 10, and 28) produced F values which were significant at the traditional .05 level. Item 16 produced an F value of marginal significance ($p<.10$). The sum of the 14 items, when treated as a separate dependent variable, also produced a significant F value. In all instances, the rated severity for the items decreased after 4 weeks on drug.

Those items with significant F values were followed up with matched *t* tests. Only comparisons between the two baselines and 4 weeks on drug are presented (no significant differences were found between the baseline measures for any of the items). All of these comparisons showed a significant decrease in rated severity between the two baselines and 4 weeks on drug except for items 3 and 28. On item 3, fidgetiness, the decrease between the second baseline and 4 weeks on drug was not significant, apparently because the mean rating for the second baseline was lower than that of the first baseline (though not significantly). On item 28, rhythmic motions, the decrease between the first baseline and 4 weeks on drug is only marginally significant. These comparisons should be interpreted with caution appropriate to the number of comparisons performed.

Clinical Global Impressions (CGI). Table 2 contains the ratings for the three items on the CGI for various combinations of times of measurement. The last column contains the F values from one-way repeated measures ANOVA. Each of the items are presented in two ways: first, analyses based on the largest sample possible for the smallest number of meaningful times of measure and, second, analyses based on a smaller sample size but representing all times of measurement.

Item 1, the rated severity of illness, indicated a significant decrease in rated severity from baseline to measures made while on drug. Row 1(a) contains values based on the same subjects represented by the CPRS ratings in Table 1. The two baseline measures did not differ from each other but both were significantly higher than the rating made at 4 weeks on drug (both $p<.05$). Row 2(a) contains the second drug measurement made at 8 weeks after drug treatment began. Here, again, the two baseline measures did not differ, nor did the two ratings made while on drug. Ratings made on baseline were both significantly higher than either rating made on drug (one $p=.07$, others $p<.05$).

Item 2, improvement in the child relative to first interview by the clinician, shows only a marginal improvement from the second

---

*Means and standard deviations (in parenthesis) are based on eight subjects. Items are rated on a 7-point scale where 1 means not present, 2 means very mild, and so on to 7 which means extremely severe. Degrees of freedom for the repeated measures ANOVA are 2 and 14 and 7 for the matched *t* test used in the posthoc comparisons.

baseline to 4 weeks on drug. When the second drug measure is included, the repeated measures ANOVA is nonsignificant even though there is a steady improvement from baseline.

Item 3, the efficacy of the drug treatment, a rating which is to reflect the relative benefit of a drug given the number of side effects that are observed, shows a significant therapeutic effect of fenfluramine at 4 weeks on drug relative to baseline measures [row 3(a)]. When the second drug measure is included, we still obtain a significant F value from the repeated measures ANOVA. Though the two ratings made on drug did not differ from each other, both were significantly higher than the baseline measure ($p = .06$ and $p = .02$).

Conclusions

In this open-label study, a variety of positive stimulating and tranquilizing effects of fenfluramine were observed: the most consistent and striking effects were increased relatedness and animated facial expression, decreases of irritability, temper tantrums, aggressiveness, self-mutilation, hyperactivity, and improved sleep pattern. Ritvo et al.

(1983) and August et al. (1985) also reported improvements in sleep pattern, attention, and social relatedness, as well as decreases in hyperactivity and stereotypies. Marked global improvement was observed in 4 children; 2 had moderate and 4 showed minimal or no change. However, in 2 children, the level of initial improvement could not be sustained over a 2-month period of active medication. Therapeutic effects occurred as early as 2 days after medication was started.

Major untoward effects included drowsiness and lethargy, excessive and uncontrollable irritability, and a transient weight loss at the end of 1 month (followed by weight gain at the end of the second month). While Ritvo did not find weight loss a problem, August et al.'s (1985) findings are in agreement with ours. Ritvo states that weight monitoring may have been flawed in his study. We used the same scale throughout the study and adhered to a strict protocol. Untoward effects seemed to be dose-dependent as they disappeared upon dosage reduction. While in the previous reports children adapted to sedation after a few days (August et al., 1985; Ritvo et al., 1983), this was not true for our patients. Actually, no child adapted to behavioral toxicity.

In conclusion, we learned the following from this open clinical trial of fenfluramine, when administered at the specified doses over a period of up to 2 months to hospitalized preschool-age autistic children under the present conditions (100% compliance and 24-hour a day careful monitoring):

1. Flexible, and not a fixed dosage schedule should be employed since the range of optimal doses was wide: 1.1 to 1.8 mg/kg/day; mean, 1.4.

2. Onset of therapeutic effects was as early as 2nd day of treatment; one child fell asleep 4 1/2 hours after the morning dose.

3. Stimulating and calming properties of drug were reflected in both therapeutic and in untoward effects.

4. The most consistent and striking therapeutic effects were increased relatedness and animated facial expression, and decreases of irritability, temper tantrums, aggressiveness, self-mutilation, hyperactivity, and improved sleep pattern.

5. Four of the 10 children showed dramat-

ic improvement: all 4 had low IQs. All 4 failed to respond to haloperidol and to special education.

6. In some children, therapeutic effects are transient.

7. In a subsample of 7 children who received separate trials of both fenfluramine and of haloperidol, 3 responded to haloperidol and not to fenfluramine; 4 responded to fenfluramine but not to haloperidol.

8. Untoward effects with fenfluramine occurred mainly above therapeutic doses and there was a good therapeutic margin. Major untoward effects were drowsiness, uncontrollable irritability, and transient weight loss.

The observed effects in our study could be attributed to antiserotonergic or amphetamine-like, or antidopaminergic properties of fenfluramine.

However, while in our previous studies of D- and L-amphetamine the potentiating effects on stereotypies were striking in most autistic children, with fenfluramine only one child showed increases of stereotypies on 3.625 mg/kg/day, a dose which was above optimal (1.787 mg/kg/day). On therapeutic doses, there was reduction of stereotypies. This observation is consistent with the preclinical literature demonstrating that fenfluramine can antagonize apomorphine-induced stereotypies in rats (Jori et al., 1974), although in our sample the reduction of stereotypies was only mild.

While the literature (Alphin & Ward, 1969) indicates that fenfluramine has mild antidopaminergic-tranquilizing properties, in our patients calming effects were pronounced: decreases of aggressiveness, temper tantrums, hyperactivity, and insomnia were observed at therapeutic doses and, at higher doses, 9 of the 10 patients were drowsy or fell asleep.

Future well-designed, carefully planned, and placebo-controlled studies involving large samples of hospitalized autistics who are homogeneous with respect to age are needed to assess critically the efficacy and the safety of fenfluramine in this disorder.

We have recently begun such a study: in this double-blind, placebo-controlled parallel group's clinical trial we will assess the effects of fenfluramine on both behavioral symptoms and on discrimination learning.

Fenfluramine: Neurotoxicity[1]

Charles R. Schuster, Ph.D.,[2] Marilyn Lewis,[3] and Lewis S. Seiden, Ph.D.[4]

Fenfluramine [(M-trifluoromethyl)-N-ethyl-amphetamine)], a secondary amine, is structurally similar to its analog the primary amine, amphetamine, and shares its anorectic effects but not its stimulant effects (Le Douarec & Neveu, 1970). Its anorectic actions are based upon its ability to release and block reuptake of serotonin from neurons (Fuxe et al., 1975; Trulson & Jacobs, 1976). Our interest in the neurotoxic effects of fenfluramine was generated in the course of investigating currently marketed anorectic drugs as part of a program of research conducted at the Drug Abuse Research Center at the University of Chicago. We investigated the efficacy, dependence potential, and possible neurotoxicity of structurally related anorectic drugs. We have established that methylamphetamine, as well as certain other related anorectics, produce long-term possibly irreversible damage to one or more monoaminergic systems in the brain (Ricaurte et al., 1982; Schuster & Johanson, 1984; Seiden et al., 1976; Wagner et al., 1979). We report here that fenfluramine is different from most other anorectic drugs because it produces evidence of long-term, possibly irreversible, changes in serotonergic neurons at comparatively low doses compared to those which suppress food consumption.

Several investigators have reported that brain serotonin levels in rats were significantly lowered several hours after the administration of fenfluramine (Duhault & Verhavainne, 1967; Opitz, 1967). Costa et al. (1971) showed that serotonin (5–hydroxytryptamine, 5-HT) brain concentrations were depleted at maximum between 2 and 5 hours after a low interperitoneal injection (10 μmol/kg) of fenfluramine and returned to only 80% of normal 48 hours post-injection. Subsequently, a number of investigators reported that the fenfluramine-induced depletions of brain 5-HT in rats lasted for weeks after drug administration was stopped (Clineschmidt et al., 1978; Harvey & McMaster, 1975; Harvey et al., 1975; Sanders-Bush et al., 1975). In these studies, brain levels of serotonin were found to gradually return to near-normal levels over a 30- to 60-day period. In addition to demonstrating a long-lasting effect upon serotonin brain levels, these investigators also demonstrated long-lasting decreases in the rate limiting enzymatic activity of tryptophan hydroxylase, serotonin uptake, and production of the 5-HT metabolite 5-hydroxyindoleacetic acid (5-HIAA). These neurochemical changes are similar to those produced by 5,6-dihydroxytryptamine (5,6-DHT), a toxin known to act on 5-HT neurons. This suggests that fenfluramine also produces a degeneration of serotonergic nerve terminals. The return of serotonin levels to near-normal in most areas suggested that the terminal degeneration was not sufficient for death of the neuron and that sprouting occurred with the formation of new nerve terminals. In addition to this neurochemical evidence for toxic effects on serotonergic nerve terminals, Harvey reported in 1975 that fenfluramine produced morphologic changes in the cell bodies of serotonergic neurons located in the ventral tegmentum of the rat brain, but not in the dorsal or median raphe nuclei (Harvey & McMaster, 1975; Harvey et al., 1975). Although this morphological evidence of cytotoxic effects of fenfluramine is controversial, it suggests that fenfluramine has two types of toxic effects on

serotonergic neurons in the rat: 1) on the terminals of 5-HT neurons in general regions of the brain, and 2) on cell bodies in a restricted region.

Studies from our laboratory have found that the dose of fenfluramine necessary to reduce food intake by 50% in the rat is 5.0 mg/kg subcutaneous (s.c.) (Schuster & Johanson, 1984). To investigate the possible neurotoxic effects of fenfluramine, two s.c. injections per day were given for 4 days over a range of doses from 6.25 to 50 mg/kg/injection. Two weeks after the last injection, rats were killed and their brains rapidly removed, dissected, and assayed for neurochemical changes as described by Heffner et al. (1980) and Ricaurte et al. (1981). In the caudate hippocampus, and cortex-limbic system, caudate serotonin was depleted by approximately 50% by all dose levels of fenfluramine. In contrast, the levels of dopamine and norepinephrine were not significantly different than controls.

To investigate the neuronal changes responsible for the depletions, we assessed the uptake of tritiated 5-HT into synaptosomal preparations of cortical cells from rats 2, 4, or 8 weeks after the 4-day administration regimen of fenfluramine. When fenfluramine was given twice daily at a dose of 6.25 mg/kg/injection for 4 consecutive days, the number of uptake sites (V_{max}) is decreased by approximately 50% of control values at 2 weeks, but is less affected at 4 weeks and is at control levels by 8 weeks post-fenfluramine. The decrease in the number of uptake sites suggests that fenfluramine damaged the terminals of serotonergic neurons, but that there was a gradual recovery over an 8-week period.

When the effects of fenfluramine were examined at 2, 8, and 16 weeks after two 12.5 mg/kg injections per day for 4 days, it was found that 5-HT levels in the caudate and cortex-limbic system fractions showed a gradual return to control levels over the 16-week period. In contrast, hippocampal 5-HT levels continued to show 50% depletions up to and including the 16-week period. The fact that the 5-HT depletion is longer lasting in the hippocampus than that found in other brain regions confirms previous findings by Harvey et al. (1975). It should be noted that the 5-HT uptake studies cited above were done with synaptosomes from 5-HT nerve terminals from the cortex, a region in which 5-HT levels show a return to normal. We presume that 5-HT uptake into synaptosomes from the hippocampus would continue to be low since the levels of 5-HT show little trend towards returning to control levels over the 16-week period. We may conclude from these studies that at a dose approximately equal to that necessary to produce a significant decrease in food intake (50%), fenfluramine produces long-term changes in 5-HT neurons. It remains to be determined whether the changes induced by fenfluramine in hippocampal 5-HT nerve terminals are irreversible.

Guinea Pigs

Fenfluramine is metabolized in the rat to norfenfluramine which has been shown to cause the release of 5-HT from neurons and to produce long-term depletions of brain levels of 5-HT (Clineschmidt et al., 1978; Sterenka & Sanders-Bush, 1979). In the guinea pig, however, fenfluramine is not changed into an active metabolite (Beckett et al., 1973). This difference in the metabolism of fenfluramine in the guinea pig allows the determination of whether the parent compound alone can produce long-term depletions of 5-HT in the brain.

Four groups of guinea pigs were used in this investigation. Group I was given 6.25 mg/kg/injection twice daily for 8 days. Group II was given 6.25 mg/kg/injection twice daily for 4 days and then 12.5 mg/kg/injection for an additional 4 days. Group III was given 12.5 mg/kg/injection twice daily for 4 consecutive days. Group IV was given saline injections twice daily for 8 consecutive days. Fourteen days after the last injection, animals were killed and the levels of 5-HT in the hippocampus determined. Animals treated with fenfluramine showed a significant dose-related depletion of 5-HT. At the higher dosage level (Groups II and III) these depletions were approximately 50%.

This study indicates that fenfluramine does not have to be metabolized to norfenfluramine in order to produce long-term depletions of brain levels of 5-HT. A similar conclusion was reached by Garattini et al. (1975) who blocked the metabolism of fenfluramine to norfenfluramine in the rat by pretreatment with SKF 525-A.

Rhesus Monkeys

In order to strengthen the prediction of neurotoxicity from animal studies to humans, it is necessary to use a number of species. It is particularly important to determine whether neurotoxicity found in rodents can be replicated in primates. Data on the long-term neurochemical effects of fenfluramine in the rhesus monkey have begun to be collected by our laboratories.

Rhesus monkeys were administered either saline (*N* = 2) or fenfluramine (*N* = 4) at doses of 10 mg/kg/injection by a s.c. route twice daily for 14 consecutive days. Two and 8 weeks later, one of the control animals and two of the fenfluramine-treated monkeys were sacrificed for neurochemical studies. Levels of 5-HT were markedly lower in the fenfluramine-treated animals in caudate, hippocampus, and somatosensory cortex at both 2 and 8 weeks postdrug. In addition, studies of the uptake of tritiated 5-HT into synaptosomal preparations from the cortex showed that 2 weeks after the last injection of fenfluramine there was a 51% decrease in the number of uptake sites (V_{max}) but no change in the affinity (K_m). This is in accord with the results of the studies in rats and suggests that in both species fenfluramine destroys 5-HT nerve terminals.

Before any conclusions can be drawn about the degree and duration of the neurotoxicity produced by fenfluramine in rhesus monkeys, a larger number of animals must be studied. Nevertheless, the concordance in the data from the rat, guinea pig, and rhesus monkeys strengthens the prediction that fenfluramine probably produces similar long-term effects on 5-HT neurons in humans. This conclusion is given support by the findings of Chase and Shoulson (1975) who demonstrated that cerebrospinal fluid (CSF) levels of 5-HIAA were significantly decreased 24 hours after a 7-day treatment regimen with fenfluramine. It would be of great significance to determine the duration of such changes in 5-HIAA levels after fenfluramine administration is stopped. Even if 5-HIAA levels return to normal in the CSF, it does not guarantee that fenfluramine does not produce irreversible changes in 5-HT neurons in restricted brain regions. Our findings in the rat that hippocampal levels of 5-HT are still significantly lower 16 weeks after the last injection of fenfluramine is in accord with previous reports of long-term depletions by Harvey et al. (1975). This suggests that certain 5-HT neurons may be more sensitive to the neurotoxic effects of fenfluramine.

The question remains: What are the implications of this pre-clinical laboratory evidence regarding long-term changes in 5-HT neurons for clinicians? When fenfluramine is used in the treatment of obesity, one must ask whether the therapeutic benefits gained warrant even the slightest risk that long-term changes in 5-HT neurons are being produced. At the very least, clinicians should be aware of this possibility in order to make a decision as to whether the drug should be prescribed. In the case of the possible benefits of fenfluramine for the treatment of autism, the problem is somewhat different. This disease may be sufficiently devastating and intractable to warrant the possible risks of long-term changes in 5-HT neurons. It is even conceivable that such depletions might be therapeutic for some autistic patients.

Before clinicians can make an appropriate analysis of the cost/benefit ratio for fenfluramine in the treatment of autism, more research is needed. At the present time, however, the findings from animal studies strongly suggest that the therapeutic benefits produced by fenfluramine must be sizable and durable in order to outweigh the potential risk of long-term, possibly irreversible, changes in 5-HT neurons in the brain.

Fenfluramine Treatment of Childhood Attention Deficit Disorder With Hyperactivity: A Preliminary Report

Maureen Donnelly, M.D.,[1] Judith L. Rapoport, M.D.,[1] and Deborah R. Ismond, M.A.[1]

Attention Deficit Disorder With Hyperactivity (ADD-H) is a common childhood disorder, with significant morbidity and a chronic course (Weiss, 1985). Pharmacotherapy with stimulant medications has been the mainstay of drug treatment (Gittelman, 1980). However, limitations of stimulant therapy—such as lack of response in about 20% of individuals, inconvenience of multiple daily dosing, possible rebound effects, abuse potential, and adverse effects such as growth suppression—have led to the investigation of alternative drug treatments (Rapoport et al., 1985).

Fenfluramine is a halogen-substituted phenethylamine derivative, presumed to act in part through serotonergic mechanisms. Acutely and at low doses, it increases central nervous system (CNS) serotonin (5-HT) activity, via 5-HT release, reuptake inhibition, and weak receptor agonist action. At high doses or with chronic use, it depletes brain 5-HT (Garattini et al., 1975; Mueller et al., 1984; Reuter et al., 1975).

Clinical and preclinical studies suggest that CNS 5-HT systems might be altered in ADD-H and that serotonergic activity might mediate stimulant drug effect (Solanto, 1984). In rats, increased 5-HT activity, by various means, is associated with decreased locomotor activity (Warbritton et al., 1978) and perhaps acquisition of behavioral inhibitory responses (McElroy et al., 1982). In autistic children, fenfluramine has been reported to decrease hyperactive behaviors (Ritvo et al., 1984). Other pharmacotherapeutic agents thought to enhance CNS 5-HT activity—namely, L-tryptophan (Brown, personal communication, 1984), chlorimipramine (Garfinkel et al., 1983), and clorgyline (Zametkin et al., 1985) have shown some beneficial effects in hyperactive populations.

This study evaluates behavioral, cognitive, and motor activity response of boys with ADD-H in a randomized, double-blind, crossover trial of fenfluramine, amphetamine, and placebo.

Method

Ten boys (mean age 8 ± 2 years) with DSM-III diagnoses of ADD-H, Conners Teacher Rating Scale (Goyette et al., 1978) Factor IV baseline ratings greater than two standard deviations above age means, and Wechsler Intelligence Scale for Children–Revised (WISC-R) full scale IQ scores of 80 or above (mean 104 ± 12) participated in a 10-week, double-blind, placebo-controlled day-hospital study. Six boys also met diagnostic criteria for Conduct Disorder and four met Developmental Learning or Language Disorder criteria. All subjects were medication-free for at least 4 weeks.

After a 1-week baseline assessment period, subjects received 3 weeks of placebo, 3 weeks of D-amphetamine (0.5 mg/kg/day in two doses), and 3 weeks of fenfluramine (week 1: (low dose) 0.6 mg/kg/day; week 2: 1.3 mg/kg/day; week 3: (high dose) 2.0 mg/kg/day, in two doses) in randomized counterbalanced order.

The children also attended school and participated in a structured group activities program while at the hospital.

The classroom teacher rated behavior daily using the 10-item Conners Abbreviated Rating Scale (Conners, 1976). Sustained attention was measured at the end of weeks 1 and 3 of each drug phase with a modified version of the Continuous Performance Test (CPT) (Rosvold et al., 1956). Daytime ward motor activity was recorded daily with an acceleration sensitive activity monitor (Colburn et al.,

---

[1] Child Psychiatry Branch, National Institute of Mental Health, Bethesda, MD 20892.

1976). In addition, weekly weights and side effects complaints (using the Subject's Treatment Emergent Symptom Scale) (ECDEU, 1976) were obtained.

Results

Data were analyzed with three- or four-way repeated measure analysis of variance (ANOVA) for drug, time (week, hour), and treatment × time interaction. Significant effects by Greenhouse Geisser probability of .05 or less were then examined by Bonferroni *t* tests.

A significant drug effect ($F = 12.76$; df 1,7; $p = .009$) was found for motor activity, though not for drug × week interaction. Motor activity significantly decreased on amphetamine ($p<.05$) compared to fenfluramine and to placebo. The latter two conditions did not differ. Figure 1 illustrates drug effects for weeks 2 and 3 of each treatment.

Behavioral ratings improved significantly with amphetamine, as opposed to placebo, treatment ($p<.05$). Fenfluramine, however, did not differ from amphetamine or placebo, indicating perhaps a weak response. Though ANOVA showed significant drug and week effects ($F = 4.80$; *df* 2,18; $p = .03$ and $F = 3.95$; *df* 2,18; $p = .05$, respectively), there was no medication × time interaction. Therefore, behavioral response to "low-dose" and "high-dose" fenfluramine did not differ. Figure 2 illustrates mean behavioral rating scores for week 3 of each medication phase.

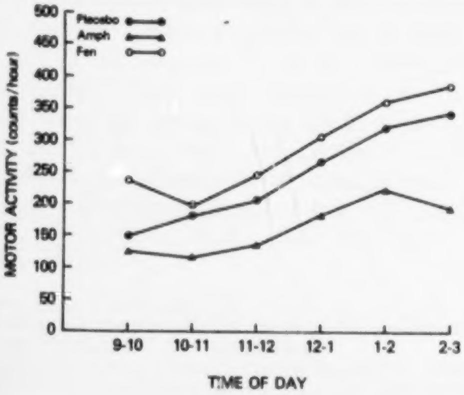

FIGURE 1. **Weeks 2 and 3: Effects of fenfluramine, D-amphetamine and placebo on Ward motor activity of hyperactive boys (*N*–*8*) (means for weeks 2 and 3 of each treatment).**

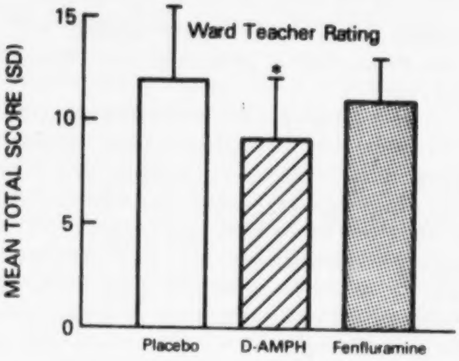

*$p< .05$ *vs.* placebo

FIGURE 2. **Ward behavioral ratings for hyperactive boys (*N*–10) on week 3 of placebo, D-amphetamine (.5 mg/kg) and fenfluramine (mean 60 mg/day).**

Performance on the CPT, a measure of vigilance, for commission errors, omission errors, and interstimulus interval did not significantly change on any drug at any time. This is an unexpected finding, as improved performance on the CPT is usually found with amphetamine treatment.

Analysis of group data for side effects showed no significant problems with either medication. One child showed clinically significant sedation for the first 3 days on fenfluramine, which disappeared thereafter.

Children's weights did not change significantly from admission to discharge from the study. Only one child had significant weight loss (2.5 kg) during the fenfluramine phase, necessitating a decrease in drug dosage. This subject's weight subsequently returned to baseline by the end of his hospitalization.

Discussion

Clinically, these results are disappointing as fenfluramine, which has less abuse potential than stimulants, does not appear to be an effective agent for the treatment of ADD-H. It had no beneficial effects on hyperactivity, classroom behavior, or attention. Though statistically there was an insignificant trend toward behavioral improvement with fenfluramine, this is probably not clinically significant.

If the assumptions of low dose and acute treatment, extrapolated from animal and adult data, have been met by the low dose (0.6 mg/kg/day) fenfluramine trial of 1 week, then these findings suggest that a serotonergic mechanism does not mediate stimulant or other drug efficacy in ADD-H. The findings also suggest that if fenfluramine is found effective in autism, then this is not secondary to a nonspecific antihyperactive action.

The Effects of Fenfluramine on Suicidal Behavior[1]

Elaine Meyendorff, M.D.,[2] Anil Jain, M.D.,[2] Lil Träskman-Bendz, M.D., Ph.D.,[2] Barbara Stanley, Ph.D.,[2] and Michael Stanley, Ph.D.[3]

Suicidal behavior is one of the few mental health problems for which no pharmacologic treatment aimed specifically at the behavior itself has been developed. Instead, this behavior is treated as a symptom of other illnesses, usually depression. However, several reports have indicated that in addition to affective illness, attempted and completed suicide occurs in other diagnostic groups, including schizophrenia and personality disorders (Barraclough et al., 1974; Dorpat et al., 1960; Robins et al., 1959).

In addition to behavioral studies which provide evidence that suicide occurs across diagnosis, there is also evidence that there may be a common biochemical deficit associated with suicide and attempted suicide.

In a series of postmortem studies evaluating the levels of biogenic amines in various brain regions of suicide victims, it was noted that the most consistent finding was that 5-HT or 5-HIAA levels were reduced in suicides compared with non-suicide controls (Lloyd et al., 1974; Pare et al., 1969; Shaw et al., 1967). Subsequent to these reports, recent studies which have examined the status of serotonergic receptors in the brains of suicide victims have indicated changes in binding which are consistent with the above reported reductions in 5-HT and 5-HIAA (Paul et al., 1984; Perry et al., 1983; Stanley et al., 1982, 1983).

In addition to postmortem studies, there have been a large number of studies which have examined the cerebrospinal fluid (CSF) levels of 5-HIAA in individuals who have attempted suicide. In these CSF studies, 5-HIAA levels from those having a history of a suicide attempt included individuals from various diagnostic groups (e.g., schizophrenia, personality disorders, and depression) (Åsberg et al., 1976; Brown et al., 1979; Van Praag, 1983). In the majority of these studies, lower levels of 5-HIAA were reported for those with a history of a suicide attempt.

The diagnostic heterogeneity of those who attempt suicide, as well as the common biochemical deficit in 5-HT they are reported to manifest, led to our decision to investigate the effects of fenfluramine on suicidal behavior. Fenfluramine has been shown to promote the release of 5-HT and to block its reuptake. Chronic exposure to fenfluramine causes a reduction in the number of 5-HT_2 binding sites in the brain. This latter effect, the reduction of 5-HT_2 binding, is apparently a common pharmacologic property of antidepressant drugs of a variety of classes. Furthermore, the time course of 5-HT_2 binding reduction parallels clinical response, it may relate to the therapeutic mode of action of these compounds (Peroutka & Snyder, 1982).

Methods

Eight suicidal patients from various diagnostic categories with a history of suicide attempts were entered into the study. All patients were free of major medical illness. Two patients had a diagnosis of bipolar disorder, depressed phase; one patient, bipolar disorder mixed; two patients, major depression with psychotic features; one patient, major depression; one patient, schizoaffective disorder; and one patient had a diagnosis of chronic undifferentiated schizophrenia. Subjects were inpatients ranging in age from 21 to 47 years, with a mean age of 35 years. Diagnosis was determined by interview performed according to the Schedule for Affective Disorders and Schizophrenia (SADS), and was established according to DSM-III criteria.

FIGURE 1. CSF levels of 5-HIAA and HVA before and after chronic fenfluramine treatment.

Supplemental information for Axis II diagnosis was obtained with the Schedule for Interviewing Borderlines, and psychological testing including a Rorschach.

Patients were maintained free of active medication for 2 to 3 weeks. During the third week they received fenfluramine placebo. This was followed by 4 weeks of treatment with active fenfluramine. Acetominophen, diazepam, or chloral hydrate were occasionally administered for relief of anxiety, insomnia, or other acute symptoms. Fenfluramine was administered in an open-dose ranging fashion with an initial dose of 20 mg orally three times daily, up to a maximum dosage of 60 mg three times daily.

Weekly measures of psychopathology and suicidality, designed to assess treatment response, were performed. These included the Brief Psychiatric Rating Scale (BPRS), the Hamilton Depression and Anxiety Scales, the Scale for Suicide Ideation (SSI), and the Suicide Assessment Scale (SAS) (Stanley et al., 1986), a scale designed specifically to assess suicidal and related behaviors.

During the drug-free period, participants had routine chemistries performed, and blood was drawn in EDTA-treated tubes for determination of platelet tritiated imipramine binding, and platelet serotonin uptake. At the end of the final week of medication a plasma sample was drawn for determination of platelet tritiated imipramine binding and serotonin uptake. Subjects received a lumbar puncture prior to the study following a drug-free period for measures of 5-HIAA and homovanillic acid (HVA). To minimize the effects of movement and diet upon CSF 5-HIAA levels, lumbar punctures were performed between the hours of 8 to 10 a.m., after the subject had had nothing by mouth and had been resting supine for 8 hours. In several subjects enrolled in the study, a second lumbar puncture was performed 24 hours after the last dose of medication.

Isolation of platelets from whole blood was performed according to Briley et al. (1980). Tritiated imipramine binding was analyzed as described in Raisman et al. (1982). Serotonin uptake was determined by methods described by Tuomisto (1980). 5-HIAA and HVA were assayed in spinal fluid with high performance liquid chromatography.

Statistical analysis was done using paired *t* tests and analysis of variance.

Results

Biochemical Findings

Chronic treatment with fenfluramine caused a significant reduction in the concentration of 5-HIAA in the CSF when compared with the values obtained prior to treatment. The 66% decrease in 5-HIAA is in contrast to the nonsignificant 18% decrease seen in HVA levels for the same patients (Figure 1).

Reductions in platelet 5-HT uptake and imipramine binding were also observed following treatment with fenfluramine. V_{max} values for platelet 5-HT uptake were reduced from 49.8±4.44 to 26.6±3.61 (pmol/10^8 platelets/min) ($p<0.005$) (Figure 2). Platelet imipramine binding was decreased from 1078±104 to 711±92.9 (fmol/mg protein) ($p<0.10$) (Figure 3).

Behavioral Ratings: Suicidal Behavior

Both scales used in this study to assess suicidality reflected a time-dependent decrease in the severity of this behavior. SSI scores were reduced to their lowest point after 4 weeks of fenfluramine treatment (Figure 4). Similarly, SAS scores were lowest after 4 weeks of fenfluramine (Figure 5). The downward trend observed for both of these measures was reversed immediately upon discontinuation of fenfluramine (Figures 4 and 5).

Measures of Psychopathology

In contrast to the uniform effect fenfluramine treatment exerted on the above measures of suicidality, it had a differential effect on psychotic and depressive symptoms. Hamilton depression scores showed a time-dependent reduction maximal at 5 weeks. However, psychotic symptoms, as assessed by the BPRS, reflected virtually no change over the entire treatment period (Figures 6 and 7).

Side Effects

With regard to side effects, subjects demonstrated a net weight loss of approximately 3 lbs, including one patient who lost 12 lbs, 4 patients who lost 4 to 5 lbs, one patient who lost 1 lb, one who gained 1 lb, and one patient gained 8 lbs. There were no clinically significant changes in either blood pressure or pulse rate throughout the active treatment

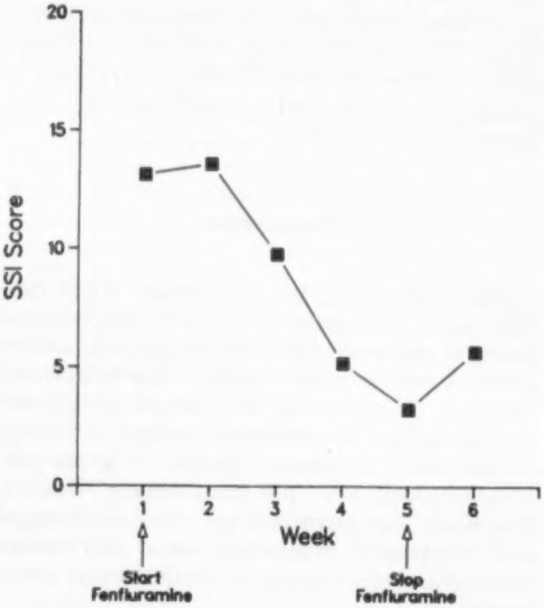

FIGURE 4. Effect of 4 weeks of fenfluramine treatment on Scale for Suicide Ideation Scores.

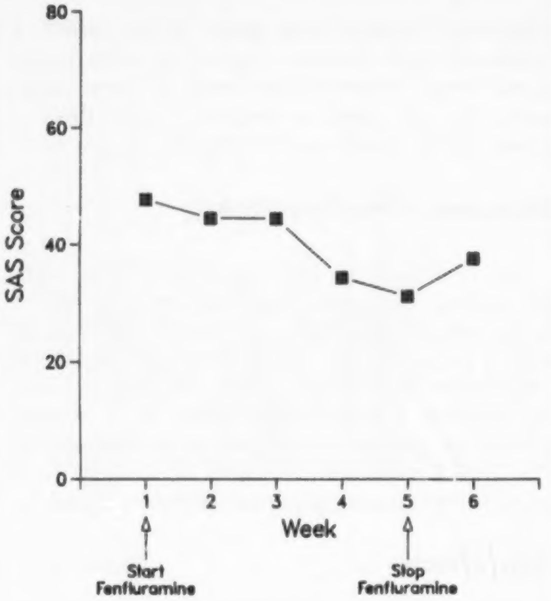

FIGURE 5. Effect of 4 weeks of fenfluramine treatment on Suicide Assessment Scale Scores.

phase of the study. No dystonia or other adverse effect was observed. Two patients with a diagnosis of bipolar disorder became manic during the treatment phase, and one patient with a diagnosis of bipolar disorder and another with a diagnosis of borderline personality became manic after discontinuation of the drug. Whether the drug induced the symptoms, or this was coincidental emergence of symptoms which were unaffected by fenfluramine, was unclear.

Discussion

The findings of this preliminary study parallel both the behavioral and biochemical findings reported for individuals who either attempt or complete suicide. The behavioral changes observed in this mixed diagnostic group indicate a consistent change in ratings of suicidality whereas changes in gross psychopathology were not consistently affected. Psychotic symptomatology was unchanged and depressive symptoms were diminished throughout the course of fenfluramine treatment.

The biochemical findings of this study were also consistent with the biochemical changes which have been noted in both postmortem and CSF studies of suicidal patients. The most consistent biochemical change which has been observed in studies of suicidal patients has been with the neurotransmitter 5-HT. In the present study, fenfluramine treatment resulted in significant reductions in peripherial and central indices of 5-HT function. The CSF measures further indicated the changes observed in 5-HT metabolism were relatively specific for 5-HT, as HVA values were not significantly altered.

The interpretations of the findings of this preliminary study are supportive of the hypothesis that suicidal behavior may be independent of diagnostic categorization and are also consistent with a serotonergic deficit. However, it must be noted that these results are of a very preliminary nature. Further, the study was conducted in a dose-ranging and open design on a relatively small patient sample. Accordingly, future studies of fenfluramine treatment of suicidal behavior should employ a larger patient sample and consider the use of a double-blind experimental design.

The Relationship of Antiobsessional and Antidepressant Effects of Tricyclic Antidepressants[1]

Matig Mavissakalian, M.D.,[2] Samuel M. Turner, Ph.D.,[2] Larry Michelson, Ph.D.,[2] and Rolf Jacob, M.D.,[2]

Antidepressant medications, primarily clomipramine, have been found effective in treating obsessive-compulsive disorder (OCD) although the relationship between their well-established antidepressant action and their antiobsessional effects remains an open question (Ananth et al., 1981; Insel & Murphy, 1981; Insel et al., 1983; Marks et al., 1980; Mavissakalian, 1982, 1983; Montgomery, 1980; Thorén et al., 1980). Observations made in 8 OCD patients treated with either clomipramine or imipramine (Mavissakalian & Michelson, 1983) revealed synchronous patterns of change in depression, anxiety, and obsessive-compulsive symptoms which, coupled with the tendency for responders to have higher initial depression ratings, tentatively supported Marks' contention (Marks, 1983; Marks et al., 1980) that antidepressant drugs may not have an antiobsessional effect independent of their antidepressant properties. However, in a more recent placebo-controlled study of 12 OCD patients (Mavissakalian et al., 1985), it was found that OCD symptoms improved significantly more with clomipramine compared to placebo, while outcome of depression was equivalent in the two groups. The discrepancy between the fate of depression and obsessive-compulsive symptomatology in the placebo group was interesting and suggested that change in these symptom dimensions can occur independently from each other. The aim of this presentation is to further explore the relationship between the antidepressant and antiobsessional effects of tricyclic drugs in the combined sample of 15 primary OCD patients who were treated with clomipramine or imipramine in the aforementioned studies.

Subjects

Table 1 presents the individual characteristics of the 15 patients who were uniformly selected to be part of two consecutive mul-

ticenter projects sponsored by Ciba-Geigy (Mavissakalian & Michelson, 1983; Mavissakalian et al., 1985). Inclusion criteria included: 1) DSM-III diagnosis of primary OCD; 2) a score of at least 56 on the Obsessive-Compulsive Neurotic Scale (*see* Assessment); and 3) a psychotropic medication-free and alcohol-free period of at least 2 weeks. Exclusionary criteria included: 1) diagnosis of primary affective disorder or major depressive episode with melancholic features, schizophrenia, and organic brain syndrome and 2) presence of physical illness precluding the use of antidepressants either because of the illness itself or because of treatment necessary for that illness.

Patients were randomly assigned to double-blind clomipramine or imipramine in the respective protocols. Initial drug dose was 50 mg/day in the first week with gradual increases to the largest tolerable level or a maximum of 300 mg/day. In order to remain in the study, patients had to be on at least a 100 mg/day regimen. Patients were seen weekly up to 6 weeks and then at 8 and 12 weeks of treatment at which time the trial ended. The tone of these sessions was supportive, and patients were encouraged to tolerate obsessions without engaging in compulsive behavior. The maximum stable dosage for the individual patients is presented in Table 1.

Major assessments included a uniform battery of tests which were administered at pretreatment, and at 4, 8, and 12 weeks posttreatment. The Obsessive-Compulsive Neurotic Scale (OCNS), a 25-item questionnaire covering commonly encountered obsessive-compulsive symptoms, was used as the patient-rated measure of change. Each item was rated on 4-point scales where 1 = none or little of the time; 2 = some of the time; 3 = a good part of the time; and 4 = most or all of the time (range 25 to 100). In addition, clinician-rated 5-point obsessive-compulsive scales were used to assess 1) frequency of obsessive thoughts (OCRS-O), 2) distress-anxiety caused by obsessive thoughts (OCRS-A), 3) frequency of compulsive behaviors (OCRS-C), and 4) interference with everyday life due to compulsive behavior (OCRS-I). On these scales, 0 = absent or none; 1 = infrequent or mild; 2 = moderate frequency or severity; 3 = very frequent or severe; and 4 = almost constant or extremely severe, incapacitating. These measures were also utilized to classify patients into responders (posttreatment ratings of ≤ 1 on at least 3 out of 4 criteria). Depression (HD-17) and anxiety (ZAS) measures consisted of the first 17 items of the Hamilton Depression Rating Scale (Hamilton, 1960) and the Zung Self-Rating Anxiety Scale (Zung, 1971), respectively.

Results

There were no significant differences on any demographic and clinical variables or pretreatment dependent measures between patients recruited from the two different studies. Nor did analysis of variance reveal significant pretreatment and improvement differences between the 5 imipramine- and the 10 clomipramine-treated patients (*see* Figure 1). For the purposes of investigating the relationship between the antidepressant and antiobsessional effects of tricyclic drugs among OCD patients, therefore, pooling of data across the two studies and the two drugs seemed justified.

Two-tailed *t* tests comparing pretreatment mean group scores and 4th week, 8th week, and posttreatment assessments, respectively, revealed significant improvement ($p < .05$) on all measures at all occasions in the samples as a whole. As shown in Table 1, 7 (47%) patients were classified as responders. Figure 2 illustrates the contrasting patterns of change between them and the nonresponders. Two-tailed *t* tests did not reveal significant differences at pretreatment. Significant differences on depression and anxiety were present only at posttreatment while differences on all obsessive-compulsive measures were significant at 4 and 8 weeks of treatment and ostensibly at posttreatment. Figure 2 also indicates an overall synchronous pattern of change between all three symptom dimensions.

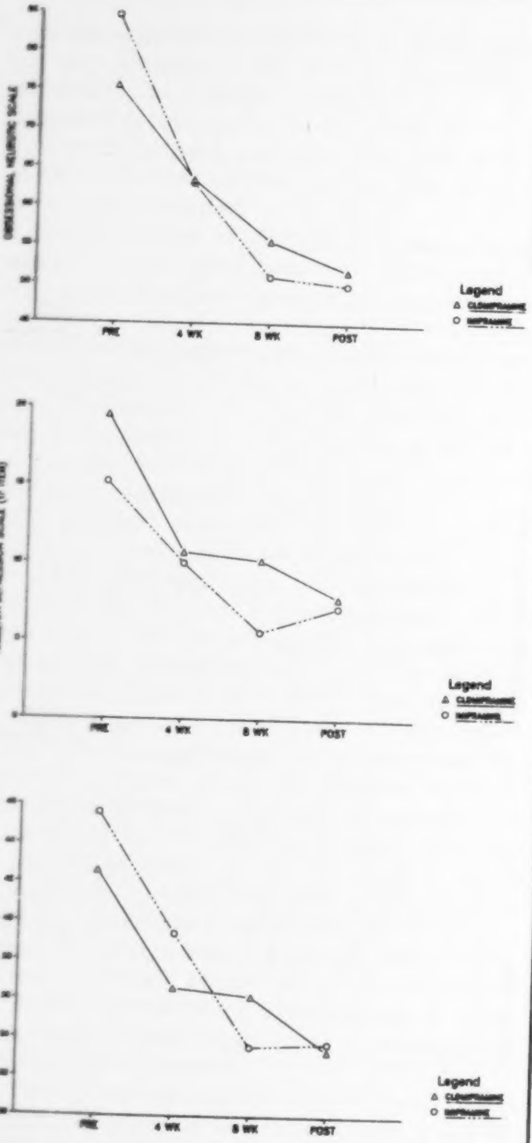

FIGURE 1. **Differential improvement of obsessive-compulsive, depressive, and anxiety symptoms with clomipramine ($N = 10$) and imipramine ($N = 5$).**

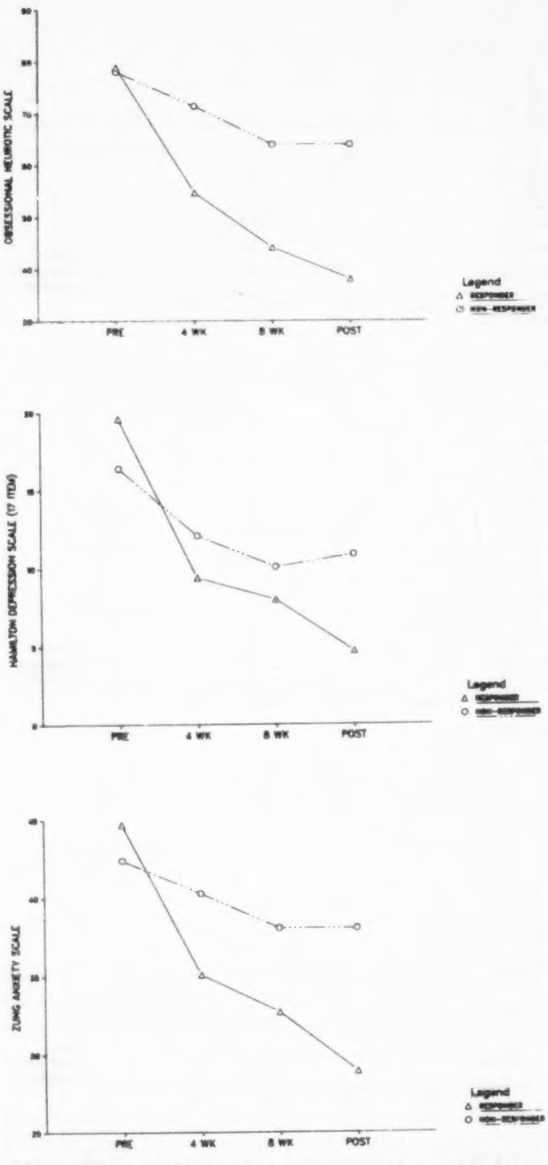

FIGURE 2. Differential improvement of obsessive-compulsive, depressive, and anxiety symptoms between responders ($N = 7$) and nonresponders ($N = 8$).

8 Weeks		
HD-17	.37	.38
12 Weeks		
HD-17	.30	.70**

*$p \leq .05$
**$p \leq .001$

To assess the degree of association between the antidepressant and antiobsessional effects, change scores in depression were correlated with change scores in obsessive-compulsive symptoms. For this purpose, the 4 clinician-rated scales were combined into a total measure (OCRS-T) to reduce the quantity of analysis required and to make its range (0 to 16) more comparable with the other scales. As shown in Table 2, there were significant correlations at Week 4, but these had decreased in strength by the 8th week and had become inconsistent at posttreatment.

Finally, the 5 patients with the lowest depression scores ($\overline{X} = 9.6$, range 4–14, s.d. $= 5.18$) were compared with the 5 patients who were most depressed ($\overline{X} = 25.6$, range 23–28, s.d. $= 2.61$). *T*-test comparisons of absolute and change scores at each assessment did not reveal significant ($p < .05$) differences on the anxiety or any of the obsessive-compulsive measures. Figure 3 illustrates the overall similarity in improvement of obsessive-compulsive symptoms in these two subgroups.

Discussion

The present findings suggest that the antiobsessive effect of tricyclic antidepressants may be at least partially independent of their antidepressant mechanisms. Although correlational analyses suggested that improvement in depression and obsessive-compulsive symptoms co-vary, most consistently in the earlier phases of treatment, and despite the overall synchronous pattern of change between these symptom dimensions, the comparison between low- and high-depressed subgroups was compelling evidence that an antidepressant effect is not a prerequisite to the antiobsessional effects of clomipramine or imipramine. Because the study was not prospectively designed to compare OCD patients with high

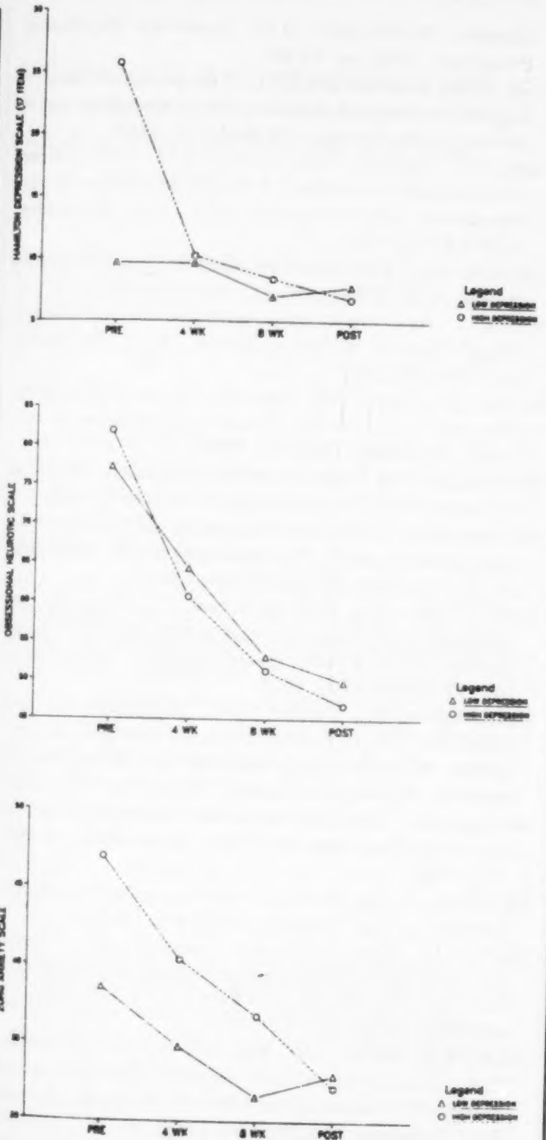

FIGURE 3. Differential improvement of obsessive-compulsive, depressive, and anxiety symptoms between high ($N = 5$) and low ($N = 5$) depressed subgroups.

and low initial depression levels, however, the findings warrant cautious interpretation. Indeed, 12 of the 15 patients had Hamilton depression scores ≥14, a level of dysphoria incurring high probability for an antidepressant effect in depressed outpatients (Stewart et al., 1983). Nevertheless, the categorization of the low depressed group appeared satisfactory not only because of the low initial levels, but also because of the very minimal and inconsequential changes in dysphoria over the course of treatment. Still, for more definitive data in this regard, placebo-controlled studies in OCD patients without appreciable dysphoria would be needed.

Several points of clinical and research interest warrant brief comment. First, and in contrast to the near maximal improvement of depression noted at 4 weeks, improvement in obsessive-compulsive symptoms continued throughout the 12 weeks suggesting that robust antiobsessional effects require long periods of treatment. Second, in this study, both obsessions and compulsions improved in a clinically significant degree with 56% and 48% pre-post reduction on their respective clinician-rated scores (details available upon request). Although it would be plausible to suggest that some of the improvement noted was due to the encouragement to apply the behavioral principles of exposure-response prevention (Foa et al., 1985), none of the 5 placebo patients treated under similar conditions (Mavissakalian et al., 1985) had improved to a level of virtual freedom from obsessive-compulsive symptoms as compared to nearly half of the sample treated with the active drugs. Thus, at the very least, it seems reasonable to conclude that clomipramine and impramine had significant facilitatory interactive effects with behavioral instructions. From a clinical vantage point, studies of the relative and combined effectiveness of pharmacological and behavioral treatments of OCD seem warranted.

Third, the equivalent improvement noted with clomipramine and imipramine is particularly interesting inasmuch as the investigation of a specific antiobsessional effect has primarily concerned clomipramine, and some studies have suggested superior clinical effects with clomipramine in comparison to other antidepressants (Ananth, 1983). The similar effects observed, on the other hand, are not entirely surprising given that, in addition to their close chemical structure, imipramine and clomipramine undergo parallel pharmacokinetic changes which control their neurobiochemical activities, i.e., they are mostly serotonergic while their active desmethyl metabolites are mostly noradrenergic (Risch et al., 1979). Although the small numbers do not permit confident generalizations, the finding has practical significance since clomipramine is still unavailable for clinical use in the United States.

Conclusion

The present data add to the literature suggesting that clomipramine, and probably imipramine, may be specific antiobsessional agents independently from their antidepressive properties. On the other hand, it is clear that a complex association exists between the antiobsessional and antidepressant effects of these drugs which may not be easily elucidated by symptom rating scales alone. A more promising approach is suggested by findings implicating clomipramine's serotonergic action in the control of obsessive-compulsive symptoms and the drug's noradrenergic action in the control of depressive symptoms (Stern et al., 1980; Thorén et al., 1980). Newer pharmacological agents with more selective action on neurotransmitter systems (Lapierre, 1983) can therefore be used to dissect the broad spectrum clinical effects of clomipramine and imipramine and to explore the neurobiological basis of OCD (Insel & Mueller, 1984; Richelson, 1983).

A Comparison of Alprazolam and Imipramine in the Treatment of Agoraphobia and Panic Disorder

Ross Rizley, Ph.D.,[1] Richard J. Kahn, M.D.,[1] Douglas M. McNair, Ph.D.,[1] and Laura M. Frankenthaler, B.A.[1]

McNair and Kahn (1981) reported the results of a double-blind clinical trial showing greater efficacy of imipramine (IMI) over relatively high dosages of chlordiazepoxide (CDZ) in the treatment of agoraphobia, panic disorder, and mixed panic-phobic syndrome. The antipanic effects of IMI were not attributable to its antidepressant effects. However, they were somewhat late in onset (6 to 8 weeks), and the level of unpleasant early side effects was fairly substantial. The effects of IMI on the agoraphobic syndrome component were complicated. There were drug interactions with initial levels of both depression and phobia which could not be unconfounded. Differences in outcome as a function of depression and phobia were substantial on IMI but relatively small on CDZ. IMI-treated subjects who were both more depressed and more phobic at baseline showed the greatest reduction of phobic symptoms.

Recently, a class of triazolo-benzodiazepines, represented by alprazolam (APZ), have shown promise in relieving both anxiety and depression. Strong evidence shows that APZ is well tolerated and effective in the treatment of anxiety (Cohn, 1981), and considerable evidence suggests its effectiveness for depression (Feighner et al., 1983). Thus, a trial of APZ for the panic-phobic syndrome seemed warranted.

Reported here are the results from a 12-week, double-blind, independent group comparison of APZ with IMI for the treatment of panic-phobic disorder. Among the questions asked were: are there differences in their relative efficacy, speed of onset, presence of side effects, and specificity of effects?

Method

Recruitment and Screening

Subjects were symptomatic volunteers recruited through newspaper advertisements, pre-screening procedures, and intensive screening interviews and workups. To be screened, respondents had to score at least two standard deviations above normative means on the Hopkins Symptom Checklist (HSCL) anxiety factor (Lipman et al., 1979), be 18 to 60 years of age, not be in psychiatric treatment, and have no contraindicated medical condition. At screening, they had medical and psychiatric examinations and self-rating assessments to ascertain that they met selection criteria including DSM-III criteria for agoraphobia, panic disorder, or study criteria for panic attacks with mixed phobias. The last group was diagnostically similar to DSM-III agoraphobics with panic in that their phobias included situations such as elevators, tunnels, bridges, or places from which escape would be difficult, but differed in that they did not clearly include the interpersonal components such as fear of crowds and leaving home alone. Accepted subjects had a 1-week placebo (PBO) washout period followed by 12 weeks of randomly assigned, double-blind, active drug plus supportive treatment with weekly visits the first month and biweekly visits for 2 months.

Measures

At baseline and repeatedly during the trial, subjects completed the Profile of Mood States (POMS) (McNair et al., 1971), an 80-item version of the HSCL providing eight syndrome cluster scores, a 7-point Global Improvement Scale, and daily, weekly, or biweekly ratings of panic and agoraphobia on scales described below. Psychiatrists repeatedly completed the Hamilton Anxiety Scale (HAM-A) (Hamilton, 1959), the Hamilton Depression Scale (HAM-D) (Hamilton, 1967), the Treatment Emergent Signs and Symp-

---

[1] Clinical Psychopharmacology Laboratory, Boston University, Boston, MA 02114.

toms Inventory (TESS) (Guy, 1976), a doctor version of the HSCL, and a 7-point Global Improvement Scale. Vital signs were recorded at each visit.

Attrition

Of 126 patients screened, 51 (40%) were accepted and began the PBO period, 7 dropped out while on PBO, and the remaining 44 were randomly assigned to an active agent by a computer program designed to balance the two groups as closely as possible for severity of phobic and panic symptoms, severity of depression, sex, and age (in that order of priority). Six of the 44 who began the active phase continued less than 1 week, and their response after baseline could not be assessed.

Completion rates for the entire 12 weeks of active treatment were 58% for IMI and 60% for APZ. However, 90% of the APZ patients completed at least 4 weeks of active treatment compared with only 71% of the IMI group. The IMI dropouts were due to side effects more often than those on APZ (4 vs. 0), with most such attrition occurring the first month.

Completer vs. Endpoint Samples

Thirty-five of the 44 patients beginning active treatment completed 4 or more weeks. This group was designated as the Endpoint Sample ($N = 35$). The Completer Sample consisted of 26 patients treated the entire 12 weeks. Efficacy and related analyses were conducted separately on each sample. Both types of analyses yielded similar results except that there were fewer significant findings favoring APZ in the Endpoint analysis despite the larger *N*. The most likely reason for the less conclusive patterns seemed to be that APZ subjects who discontinued treatment between 4 and 8 weeks did not improve and differed from those who completed the trial, while this was far less true for IMI. Data from the Completer Sample were used for the principal comparisons reported below.

TABLE 1

Sample Characteristics
($N = 26$)

Current Age	37.9
Age First Episode	19.5
Women	62%
Education	Some college
Duration Current Episode	2 to 3 years
Prior Psychotropic Treatment	73%
Diagnosis	
Agoraphobia Without Panic	8%
Agoraphobia With Panic	42%
Mixed Phobia With Panic	38%
Panic Disorder	12%

Sample

Table 1 displays the major clinical and demographic characteristics of the Completer Sample at baseline, just prior to beginning active medication. They are very similar to the groups studied by McNair and Kahn (1981) and by Zitrin et al. (1976). Diagnostically, over 90% reported panic attacks and over 85% reported substantial phobic and avoidance behavior. Table 2 displays mean scores at screen and after PBO on the HAM-A, HAM-D, and *t*-scores on the POMS tension-anxiety and depression-dejection factors. Psychometrically and clinically, depressive symptom levels were low. Drug groups were very similar at baseline.

Medication

During the PBO period, all subjects received 1 capsule twice a day (b.i.d.). During the 12-week active phase, they received matching capsules containing either 25 mg IMI or 0.5 mg APZ. Dosage actually taken is in Table 3. Based on counts of returned med-

TABLE 2

Sample Means Pre and Post Placebo Washout

	Pre	Post
Hamilton Anxiety	14.7	12.8
Hamilton Depression	10.5	9.0
POMS Normative T Scores		
Tension-Anxiety	59.0	54.0
Depression-Dejection	53.0	49.0

TABLE 3

Dosage
(mg daily)

Week	Alprazolam	Imipramine
2	1.5	70.0
4	2.3	112.5
6	2.5	127.5
8	2.7	132.5
10	2.6	130.0
12	2.8	132.5

ication, compliance with prescribed dosage was above 95%. Maximum protocol daily dosages were 4.5 mg APZ and 225 mg IMI. The mean daily IMI dosage of 132.5 mg during the final 2 weeks was almost identical to that in the IMI versus CDZ study reported by McNair and Kahn (1981). Five IMI cases required low dose (10 mg) capsules, but no low dose APZ was required.

Efficacy Results

One-way analysis of covariance (ANCOVA) was the principal statistical procedure, with the pre-active, post-PBO score as the covariate. Because the groups were well matched for initial severity, interpretation of the ANCOVA results was straightforward.

Panic Cluster

Self-ratings on a Daily Panic measure consisting of two HSCL items ("Suddenly scared for no reason" and "Spells of terror or panic") scored on a 0 to 3 point scale were completed each evening and phoned in the next day. The results showed a trend toward lower panic levels in the APZ group by the latter half of week 1 ($p<.10$). By week 4, the APZ group was significantly lower on Daily Panic ratings than the IMI group with a trend continuing through week 5. The superiority of APZ to IMI during the early weeks suggests faster onset of action. The IMI group changed relatively little until after 5 weeks, when they appeared to catch up with the APZ-treated patients.

Weekly and biweekly Panic Cluster self-ratings included the two items from the Daily Panic measure plus three items from the POMS ("Desperate," "Terrified," and "Panicky"), scored on a 0 to 4 point scale. The results indicated comparable improvement in the two drug groups although there was a trend at week 4 in favor of APZ. This is consistent with results from the Daily Panic measure suggesting faster relief with APZ.

A slightly modified version of Klein and Zitrin's Acute Panic Inventory focused primarily on distress during the past month from signs and symptoms of panic attacks. Obtained at baseline and at 12 weeks, the Panic Distress subscale results showed that APZ subjects improved significantly more than those on IMI ($p<.05$). Thus, convergent evidence from the daily, weekly, and pre-post panic measures indicated more rapid and greater efficacy for APZ in reducing the distress from panic symptoms.

Agoraphobia

Daily and weekly Agoraphobia Distress measures were collected in the same manner as for Panic. The 5-item cluster is shown in Table 4. Except for one item (fear of fainting in public), it is identical to the HSCL phobic-anxiety factor.

On both the Daily and the Weekly Agoraphobia Distress measures, there was a trend at week 4 favoring APZ ($p<.10$). However, doctor ratings of agoraphobic symptom severity on a global 7-point scale failed to discriminate between the active agents. Overall, there was little evidence of a differential drug effect.

Anxiety

There were no significant differences between groups on self-rated anxiety on a daily measure (composed of 5 of the 12 items from the HSCL anxiety factor), on the weekly

TABLE 4

Agoraphobia Cluster (HSCL-80)

Feeling afraid in open spaces or on streets
Feeling uneasy in crowds, shops, or movies
Fear of going on buses, subways, or trains
Being afraid to go out of house alone
Feeling nervous when left alone

POMS tension-anxiety factor, or on the weekly, full HSCL anxiety factor. However, psychiatrists' ratings of anxiety on both a 7-point global HSCL anxiety scale and on the HAM-A showed early differences favoring APZ. The more striking results were from the HAM-A (Figure 1). By the first week, and continuing through the first month, the APZ group was rated as significantly less anxious.

Global Improvement

Doctors and patients independently rated Global Improvement "since beginning medication" on 7-point rating scales. In both cases, the results favored APZ, although the pattern of significant treatment effects differed. Psychiatrists saw the clear APZ advantage as early as 2 weeks ($p<.05$), and it continued during the first month. Patient Global Improvement showed APZ to be more effective at 4 weeks and during the final month (Figure 2).

Depression

The subjects were not highly depressed. Baseline POMS depression means were at the 50th percentile relative to unselected college student norms and at the 24th percentile compared with psychiatric outpatient admission norms. HAM-D means also were low relative to the minimum scores of 18 to 21 often required for outpatient antidepressant drug trials, and no patient in the Completer sample had HAM-D scores greater than 15 after washout. However, results from several measures of depressive symptomatology were of interest. At 2 weeks, psychiatrists rated the APZ group as significantly less depressed on the HAM-D ($p<.01$), although there were no further significant differences. It is well known that the HAM-D includes components of both anxiety and depression, and the result may only reflect decreased anxiety. Given the growing body of evidence suggesting APZ is effective in decreasing depression, it is also possible that there was a small but genuine decrease in subclinical depression.

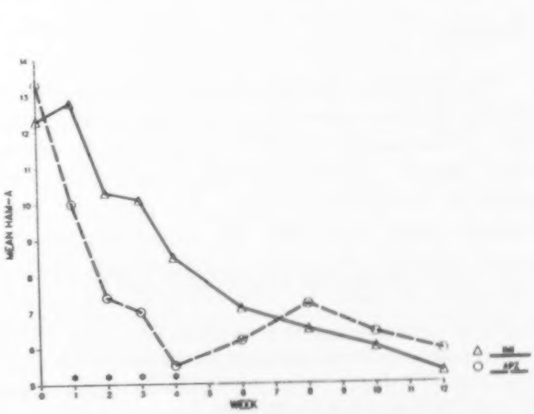

FIGURE 1. **Hamilton anxiety ratings (*$p<.05$).**

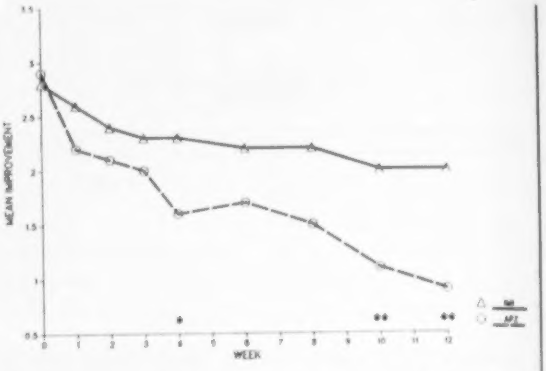

FIGURE 2. **Patient global improvement ratings (*$p<.05$; **$p<.01$).**

Self-ratings on two depression measures consistently favored APZ at every visit. Results from the POMS depression-dejection factor showed the APZ group to be significantly less depressed at week 2 ($p<.05$), but not thereafter. Stronger evidence was found in increased POMS elation scores, where significant findings favored APZ at 2, 6, and 12 weeks ($p<.05$).

Other Effects

The POMS vigor factor, a measure of general alertness and arousal, showed the APZ group to be more alert, efficient, and vigorous after 2 weeks ($p<.01$). Subsequent differences on vigor continued to favor APZ, but not significantly (although there were trends at 10 and 12 weeks).

Psychiatrists rated patients' anger-hostility using the global HSCL scale. The IMI group was less angry by week 8 ($p<.10$) and significantly less so by week 12 ($p<.05$). It is important to note that the APZ Completers did not show increased anger over the 12-week trial, but simply a smaller decrease than IMI-treated subjects.

Endpoint and Completer samples were analyzed for subjects' self-ratings of HSCL anger-hostility. There were no significant differences between the two Completer groups, but there were interesting relative differences between the Completer and Endpoint groups for each drug. Results from the Completer and Endpoint samples were virtually identical for IMI, but not for APZ. APZ patients who terminated the study between 4 and 8 weeks had increases on this measure relative both to their baseline and to the Completers. It is possible that APZ exacerbated anger-hostility in a subgroup of patients, but it is unclear whether this reaction was a reason for their premature termination.

Side Effects

A majority of patients in both groups reported drowsiness, but significantly more IMI cases reported dizziness, constipation, sweating, and dry mouth ($p<.05$). IMI significantly elevated supine diastolic blood pressure relative to APZ by the first week, and the elevation continued throughout (Figure 3). McNair and Kahn (1981) also reported that IMI elevated diastolic blood pressure relative to CDZ.

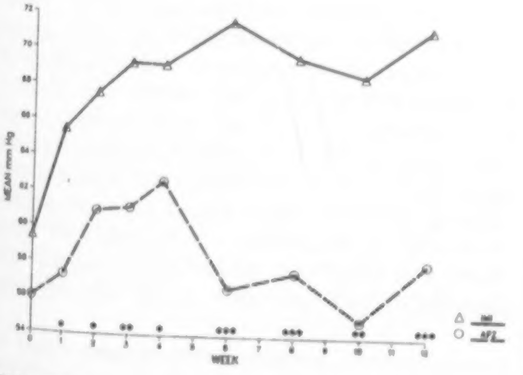

FIGURE 3. Supine diastolic blood pressure (*$p<.05$; **$p<.01$; ***$p<.001$).

Relation Between Anti-Panic and Anti-Agoraphobic Action

While there was evidence that the APZ group improved on both panic and agoraphobia, there was no indication that improvement occurred earlier in one component than the other. Actually, in neither group was there evidence of differential speed of onset of action for panic versus agoraphobia. This is also consistent with the results of the earlier IMI-CDZ trial (McNair & Kahn, 1981).

Summary

These results appear to replicate the earlier study by McNair and Kahn (1981) demonstrating the efficacy of IMI in the treatment of panic-phobic disorder. In addition, they support the efficacy of the newer benzodiazepine, APZ, in the treatment of this syndrome. Moreover, APZ showed significantly earlier onset of action and fewer side effects than IMI. In addition to the anti-panic effects, there may be a significantly greater and faster boost in feelings of well-being (elation and vigor) even when pre-treatment levels of depression are low. Finally, there may be some advantage of IMI over APZ in reducing anger. The findings also suggest a small proportion of patients fail to respond well to APZ after 4 to 8 weeks of treatment, but the number of such patients in this trial was too small to clearly characterize.

Taper Withdrawal Studies With Alprazolam in Patients With Panic Disorder and Agoraphobia

John C. Pecknold, M.D.,[1] and Richard P. Swinson, M.D.[2]

Introduction

Since the introduction of chlordiazepoxide in the 1960's, the benzodiazepines have become the major therapeutic modality in the treatment of anxiety and insomnia. New work indicates that the triazolobenzodiazepine alprazolam is also effective in the treatment of panic disorder (Klerman et al., 1986). Most authors focus primarily on efficacy and patient acceptance. However, the problems of tapering and discontinuing medication have become increasingly important. Physical dependence on high doses of chlordiazepoxide has been described by Hollister et al. (1961) and later by Covi et al. (1973). Since then, withdrawal reactions have been described with virtually all current benzodiazepines (Swinson et al., in press).

Evaluation of phenomena associated with the stopping of anxiolytic medication requires careful differentiation among physical dependency, rebound phenomena, and the return of the pre-existing condition. The cessation of pharmacological treatment in chronically anxious or insomniac patients and in those for whom the existing crisis has not been resolved may result in the return of the pre-existing syndrome. A rebound phenomenon implies the recurrence of pre-existing symptoms in an exaggerated way with greater intensity than before treatment. A withdrawal syndrome implies that tolerance has developed to the drug and that the presenting symptoms are pharmacologically derived in a direction opposite to the pharmacological action of the drug. Dependence on the compound thus derives from a physiological basis. This particular syndrome has also been referred to as the onset of new symptoms (Lapierre, 1981).

The present study is a careful assessment of patients who have been on an 8-week trial of either alprazolam or placebo for the treatment of panic disorder with agoraphobia and who were followed on a 4-week taper and a 2-week post-taper weekly assessment schedule.

Methods

As part of the cross-national collaborative panic disorder study, subjects with panic disorder and agoraphobia or limited phobic avoidance were enrolled in five centers in the United States, two in Canada, and one in Australia. Those meeting the DSM-III (Diagnostic and Statistical Manual—3rd ed., 1980) criteria modified for the study were randomly assigned to either alprazolam or placebo for an 8-week period of treatment. All patients then underwent a 4-week gradual tapering of medication and a final 2 weeks in which they were assessed. During the taper period, medication was withdrawn no faster than 1 mg in every 3 days and, for the most part, 4 weeks were taken to accomplish that. During the 2 weeks post-taper, patients were permitted to take placebos on an as-needed basis. The two Canadian sites at St. Mary's Hospital in Montreal and the Toronto General Hospital in Toronto studied the taper withdrawal phenomenon according to the following protocol. In addition to the time and dosage schedule mentioned above, patients were assessed on a weekly basis with the following instruments: the Panic Attack Scale, the Disability Scale (DISS), the Hamilton Anxiety Rating Scale (HAM-A), the Hamilton Depression Rating Scale (HAM-D), the Sheehan Patient-Rated Anxiety Scale (SPRAS), the Sheehan Clinical Rated Anxiety Scale (SCRAS), the Patient's Global Im-

[2] University of Toronto, Toronto General Hospital, Toronto, Ontario, Canada.

provement, the Physician's Global Improvement, the Symptoms and Side Effect Checklist, the Phobia Scale, the Benzodiazepine Withdrawal Checklist (BWCL), the Merz, and the SCL-90. These assessments were done weekly during the entire 14-week period with the exception of the BWCL and Merz which were done at baseline, at week 8, and then weekly during the taper and post-taper. In addition, patients completed a diary on a weekly basis which itemized the numbers of panic attacks, whether they were situational or spontaneous, their intensity and duration, as well as their outings and the intensity of discomfort on their outings.

Population

Of the 61 evaluable patients originally placed on alprazolam after a 1-week washout, 58 patients completed the 8-week trial but only 33 completed the withdrawal study. All patients were eventually tapered off alprazolam.

Of the 58 evaluable patients who initially enrolled on placebo, 49 patients completed the drug trial but only 21 patients completed the withdrawal study. Table 1 shows the demographic variables of patients who completed not only the 8-week active treatment but also the 6 weeks of taper withdrawal. Statistical analysis was completed using analysis of variance and a regression analysis for the Panic Attack Scale.

Results

Panic Attacks: Combined situational and spontaneous panic attack data are presented as derived from the daily patient diaries and the Weekly Panic Attack Scale. The group as a whole is presented in Figure 1. In the group as a whole the problem is that we are offering data during the withdrawal period only from those patients on placebo who were able to continue on medication, and they represent only a fraction of the starting group.

TABLE 1

Demographic Data by Drug Group
(Post-Taper Week 2 Completers)

	Alprazolam	Placebo
Number of patients	32	21
Mean age (S.D.)	31.8 (10.7)	32.3 (8.5)
Female	59.4%	57.1%
Male	40.6%	42.9%

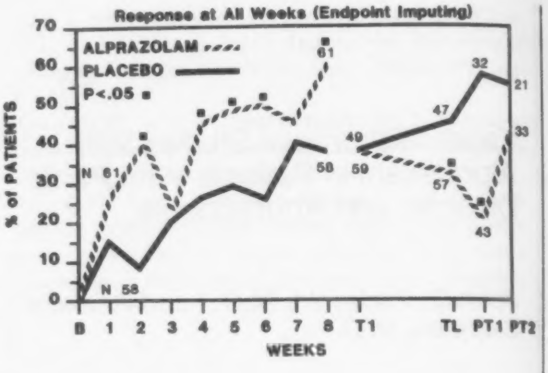

FIGURE 1. Percentage of patients with "o" panic attacks.

Rebound Panic: The criteria for rebound were set at the following: a 50% increase over baseline values and a change of at least three panic attacks. In 28% of alprazolam patients rebound is shown to occur; one patient on placebo (a nonresponder) also had a rebound.

The Figures show the response for the group as a whole with all available data (Figure 2).

Rebound Anxiety: The criteria for rebound anxiety on the HAM-A were an increase of 50% over the baseline levels and a change in score of 3. Twenty-two percent of patients on

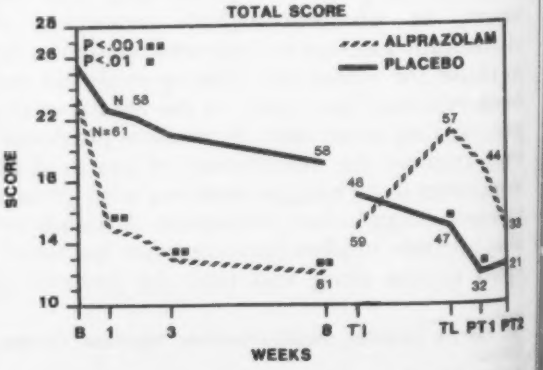

FIGURE 2. Hamilton anxiety scale.

alprazolam had rebound; 2 patients on placebo also had rebound.

Severity of phobias overall shows a similar pattern to the HAM-A with significant decrease in the alprazolam group only after 1 week of medication and thereafter, and a return of phobia during the taper with a drop to previous gains by the end of post-taper week 2. Work and Social Disability scales showed a similar pattern to the severity of phobias.

Benzodiazepine Withdrawal Checklist (BWCL): Our criteria for the emergence of new symptoms included the definition that the patients had never before had the symptoms, that they were seen to occur on the BWCL, and they had to occur during the final taper and withdrawal period. They divided into the percentage who had no new symptoms, the percentage who had mild new symptoms, and the percentage who had severe new symptoms. On the BWCL there was a significant drop in symptoms for the alprazolam versus placebo group during the 8 weeks of study representing primarily the various symptoms of anxiety. During the withdrawal period, the last week of taper and the first post-taper week, the trial score rose to above baseline level (significantly higher than placebo patient group) but returned to nonsignificant levels by the end of post-taper week 2. Table 2 shows the syndromes in four alprazolam patients.

TABLE 2

Benzodiazepine Withdrawal Checklist (New Symptoms — Last Taper/First Post-Taper Weeks: Patients With Three or More New Symptoms)

Patients	Last Taper Week	First Post-Taper Week
#203 Alprazolam	Blurred vision Clouded sensorium* Dysosmia*	Muscle cramps* Blurred vision

#49 Alprazolam	Blurred vision Headaches Paresthesias Muscle cramps*	(nothing)
#36 Alprazolam	(nothing)	Blurred vision Heightened sensory perceptions Paraesthesias Muscle cramps*

*Patient not asked about symptom during weeks 1-7 of acute study.

Conclusion

We report that despite a 4-week taper period, many patients have a symptomatic withdrawal. Very few of the patients on alprazolam were able to continue through this period without a return of symptoms. This occurred despite the excellent therapeutic success during the 8-week active treatment. Furthermore, we document the presence in a proportion of patients of panic rebound. The measurement, namely the Panic Attack Scale, is backed up by a daily diary questionnaire which gives a behavioral measurement of the occurrence of the panic attacks. The findings on the panic are different from those observed with the HAM-A. Twenty-five of our 60 patients had rebound; of panic (50%), of anxiety (32%), and both panic and anxiety (20%). Most of the patients with panic disorder did not have panic rebound but rather had a gradual return of the original syndrome. There is, however, a peaking during the latter end of the taper and the beginning of the drug-free period that shows rebound. This is proportional in fact to the onset and dosage schedule during the efficacy period.

The behavior of the placebo responders also shows a return of symptoms after discontinuation of the medication which documents a kind of psychological worsening. However, none of these patients had the type of rebound found in the active alprazolam group.

A small minority of patients have the development of new symptoms despite the tapering. This is related to the high dosage levels of medication and may be found with most benzodiazepine withdrawal studies.

Two important clinical questions are addressed by this withdrawal data: the first is the adequacy of the length of trial. Our patients were treated for an 8-week period with a 4-week taper and then discontinued. There was a considerable relapse. This finding was also seen in the study of Solyom et al. (1981) in which phenelzine was the drug used in comparison with placebo. Perhaps panic disorders are similar in some respect to depressive disorders in terms of length of treatment required. Certainly, more detailed comparison of short-term treatment period, namely 8 weeks, and a longer-term treatment period, namely 6 months, is required. It is very likely that patients with panic disorder and agoraphobia require a minimum of 6 months' medication, and a premature discontinuation of medications may trigger a relapse.

The second question has to do with the taper. Our patients had a 4-week period in which their medication was tapered mostly at 1 mg reduction every 3 days. Furthermore, at the end of the period the medication went from 1 mg to 0. The taper schedule should perhaps be much more prolonged with decrements in the dosage but a continual division over time, inasmuch as the pharmacokinetics of alprazolam tend to require divided dosages. This taper perhaps should be accomplished over a more prolonged period, possibly a 2-month period rather than a 4-week period. Nonetheless, a proper study of taper after a prolonged 6-month trial of the drug would be informative.

Finally as to the issue of tolerance and dependency, it appears that our patients do not have a tendency to increase the dosage and this is confirmed by other withdrawal schedules (Dupont & Pecknold, 1985). My impression is that the dependency resides more in the development of new symptoms and rebound and that the gravity of those symptoms is more likely to cause a prolonged period of drug taking. Once again, it is likely that a proper therapeutic interval, namely 6 months, would result in an easier period of taper and withdrawal. Certainly further studies comparing a short-term administration period with a longer-term administration period are required. Furthermore, a more prolonged taper appears to be highly desirable.

Amitriptyline and Haloperidol in Unstable and Schizotypal Borderline Disorders[1]

Paul H. Soloff, M.D.,[2] Anselm George, M.D.,[2] Swami Nathan, M.D.,[2] Patricia M. Schulz, M.S.W.,[2] Richard F. Ulrich, M.S.,[2] and James M. Perel, Ph.D.[2]

Empirical study of the borderline syndrome delineates two statistically independent but overlapping dimensions to this disorder, defining a spectrum of symptoms with affective instability at one extreme and mild thought disorder at the other. Separated in DSM-III (Diagnostic and Statistical Manual—3rd ed., 1980) into an unstable borderline personality disorder (BPD) and a schizotypal personality disorder (SPD), the two dimensions co-exist in over half of clinically defined borderline patients (Spitzer & Endicott, 1979; Spitzer et al., 1979). The heterogeneity of symptoms presented by borderline patients confounds efforts to define a single treatment of choice. The affective, schizotypal, and impulsive-behavioral symptoms characteristic of these patients are treated with a wide variety of antidepressants, major and minor tranquilizers, and even anticonvulsants, without systematic proof of efficacy or empirically defined guidelines. Treatment is further complicated by a lack of agreement on the target symptoms for chemotherapy, on the delineation of state from trait manifestations of the disorder, and on the responsiveness of each to chemotherapy. To address these issues, we are conducting a first double-blind, placebo-controlled study of antidepressant and neuroleptic medication in acutely symptomatic, criteria-defined borderline patients. Our objectives are twofold: 1) to determine the differential efficacy of an antidepressant (amitriptyline: AMI) and a neuroleptic (haloperidol: HAL) medication against the affective, schizotypal, and impulsive-behavioral presentations of acutely symptomatic borderline patients; and 2) to test the hypothesis that medication response can define clinically meaningful borderline subtypes. Following current clinical prejudice, we predicted preferential responsiveness of schizotypal borderlines (SPD) to haloperidol and unstable borderlines (BPD) to amitriptyline.

Method

Patients for this study were referred from both inpatient and outpatient divisions of the Western Psychiatric Institute and Clinic of the University of Pittsburgh. Following informed consent, and a thorough medical and psychiatric evaluation, Gunderson's Diagnostic Interview for Borderlines was used to define a study sample with a cut-off score of 7 or greater required for inclusion (Kolb & Gunderson, 1980). A DSM-III subtype diagnosis of BPD, SPD, or Mixed BPD/SPD was made on the basis of direct patient interviews. Exclusion criteria for chronicity, medical disorders, and organicity were adopted from Gunderson et al. (1975). Co-morbidity on Axis I was defined by the Schedule for Affective Disorders and Schizophrenia (SADS) interviews with exclusion for schizophrenic disorders, major depression with psychosis, and bipolar related disorders in either current (SADS) or lifetime (SADS-L) experience. Major depression without psychosis is reported in 14% to 50% of borderline patients and was not an exclusionary criterion but was coded for separate statistical analysis (Kroll et al., 1981; Pope et al., 1983). Following a medication-free period of at least 7 days, patients were required to demonstrate

continuing symptom severity defined by the Global Assessment Scale (GAS≤50) and *either* the Hamilton Rating Scale for Depression-24 item (HAM-D≥17) *or* the Inpatient Multidimensional Psychiatric Rating Scale (IMPS≥66).

Patients were randomly assigned to haloperidol (HAL) (2 mg), amitriptyline (AMI) (25 mg), or placebo (PLC) (tablets) with titration in 1 week up to a daily maximum of HAL 12 mg, AMI 150 mg, and PLC 6 tablets. (Early experience prompted a reduction in the daily maximum haloperidol dose to 6 mg.) Medication trials lasted 5 weeks with weekly self- and observer-rated measures of mood [HAM-D-24, Beck Depression Inventory (BDI)], schizotypal symptoms [Inpatient Multidimensional Psychiatric Rating Scale (IMPS), Schizotypal Symptom Inventory (SSI)], and global functioning [Global Anxiety Scale (GAS), Symptom Checklist-90 (SCL-90), and Ward Scale of Impulse Action]. Two of these scales, the SSI and the Ward Scale, were adapted from other sources for this study. The SSI is a symptom checklist with an associated severity scale which incorporates all eight of Spitzer's DSM-III Schizotypal criteria (Spitzer et al., 1979), seven of Khouri's discriminating symptoms for Schizotypal disorder (Khouri et al., 1980), and three of Meehl's diagnostic criteria for schizotypy (e.g., ambivalence, anhedonia, pan-anxiety) (Meehl, 1964). The Ward Scale of Impulse Action is derived from the Impulse Action section of Gunderson's Diagnostic Interview for Borderlines (DIB) and lists 12 behavioral items (with an associated severity scale) which are characteristic of borderline patients in long hospital stays (e.g., self-mutilation, manipulation of staff, suicidal threat, etc.). The Ward Scale is scored weekly by the patient's primary nurse while all other observer measures are scored by two raters (P.H.S., P.M.S., or A.G.) during a weekly research interview. Weekly plasma levels were drawn and analyzed for HAL and for the AT+NT metabolites of AMI to allow for control for systemic exposure.

Statistical Analysis

Specific tests for medication effects and differences between groups were performed by Analysis of Covariance (ANCOVA) using Week 1 (baseline) as the covariate and the average of Weeks 5 and 6 as outcome. Our study hypothesis predicted that patients with a preponderance of affective symptoms would respond preferentially to AMI while those with more schizotypal symptoms would do better on HAL—and both would improve more on medication than on PLC. Because of the heterogeneity of affective and schizotypal symptoms presented by these patients, we felt it desirable to have a composite measure of change which reflects overall symptom severity and direction of change (i.e., between affective and schizotypal poles). To address our study hypothesis and complement the conventional ANCOVA for specific medication effects, a composite measure of overall change was constructed from a factor analysis of rating scales reflecting affective or schizotypal pathology. These included the HAM-D-17; Beck Depression Inventory; SCL-90: Hostility and Psychoticism Subscales; IMPS: Intropunitiveness, Hostility, Paranoia, and Perceptual Distortion Subscales; SSI; and GAS.

Taking the unrotated factors of these selected scores defined the first two components of variation, namely, an overall measure of severity and a subsequent bipolar factor which presumably contrasts affective and schizotypal symptoms. The existence of a severity factor and a bipolar factor is the standard result of factoring among a set of measures that are all positively correlated. The first factor provides a robust measure of severity to be used to test the multivariate hypothesis of symptom differences favoring a group. The second factor provides a bipolar measure of affective vs. schizotypal symptom pattern. Constructed as a contrast of two equally weighted extremes, the second factor will be less robust than the severity factor, owing to measurement issues. With care, it can be used to test for the hypothesized interaction of medication and symptom polarity (e.g., affective vs. schizotypal). Finally, using both the severity factor score and baseline scores as covariates, a separate ANCOVA can be performed on each of the outcome scales to "partial out" the effects of severity to see if treatment has any unique effect independent of severity.

(two-tailed tests) N: HAL = 21, AMI = 20, PLC = 20
[a]Baseline scores are covariates. Greater improvement noted as X>Y.

Factor analyses were performed each week separately for Weeks 1, 5, and 6. The results were quite similar at each. Factors were operationalized by giving equal weights to variables loading on a factor, and were standardized across all periods to have an overall mean of 50 and a standard deviation (s.d.) of 10, scoring across all data. Change on this standardized measure is in s.d. units (×10). Higher scores indicate greater severity on the first factor and an excess of affective traits on the second.

Results

Sixty-four patients have entered protocol to date, 49 women and 15 men, with an age range of 16 to 53 (median age 25 years). Among this sample were 51 inpatients recruited from consecutive acute admissions and 13 outpatients who met all inclusion, exclusion, and continuation criteria but refused or did not require hospitalization. By DSM-III criteria, 43.8% are diagnosed as "pure" borderline disorder, 50% as mixed borderline and schizotypal disorder, and 6.2% as "pure" schizotypal disorder. (The "pure" SPD patients are included in the mixed BPD/SPD sample for analysis. It should be noted that these are DIB-defined borderline patients with prominent schizotypal symptoms in the context of otherwise typical borderline affect, impulse, and interpersonal relatedness. These patients are *not* the isolated affectless schizotypes related to the schizophrenia spectrum) (Soloff & Millward, 1983).

Random assignment resulted in 23 HAL trials, 20 AMI trials, and 21 PLC trials. Average daily medication dosage by Day 42 was 7.24±3.19 mg for HAL and 147.62±13.47 mg for AMI. Analysis of plasma levels indicated a mean (±s.d.) of 11.87 (±11.68 ng/ml) for HAL and 244.74 (±73.07 ng/ml) for AT+NT by Day 35 (i.e., after 4 weeks of treatment). Assuming a minimum therapeutic range of 160 ng/ml–200 ng/ml for AT+NT, all but one inpatient achieved minimum therapeutic range by Day 35.

Three patients terminated the study before completing 2 full weeks of medication (Day 21) which was defined as the minimum duration required for inclusion of data. Two patients terminated for adverse medication effects: extrapyramidal side effects in one inpatient, unwitnessed hives in an outpatient, both on HAL. One inpatient on PLC terminated the study before Day 21 for reasons of personal convenience and left the hospital despite remaining symptomatic. These three trials are not included in end-point analyses, reducing the sample to 61. An overview of preliminary pharmacotherapy outcomes is given in Table 1.

Significant medication effects (i.e., $p<.05$) with baseline scores as covariates were found exclusively on self-rated measures: SCL-90 Somatization, Interpersonal Sensitivity, Anxiety, Hostility, Paranoid Ideation, Psychoticism factors, and the SCL-90 General Severity Index. Near significance ($p<.1$) was achieved on SCL-90 Obsessive Compulsive, Phobic Anxiety and Additional factors, and the BDI. It is noteworthy that the *observer-rated* measures of depression, psychoticism, and global functioning—i.e., the HAM-D, IMPS, SSI, and GAS—did not demonstrate significant medication effects.

Between-group comparisons produced clear differences. HAL was significantly superior to PLC (i.e., $p<.05$) on a broad spectrum of symptom patterns including SCL-90 Somatization, Obsessive-Compulsive, Interpersonal Sensitivity, Anxiety, Hostility, Phobic Anxiety, Paranoid Ideation, and Psychoticism factors; the SCL-90 General Severity Index; and the BDI. (Trends were apparent on SCL-90 Depression; IMPS: Hostile Belligerence and Conceptual Disorganization; the SSI; and the Ward Scale of Impulse Action.) In contrast, AMI proved significantly superior to PLC only on one scale, the ill-named SCL-90 Additional factor, a scale defined largely by depression items (e.g., poor appetite, trouble falling asleep, early morning awakening, guilt, and thoughts of death and dying). Changes favoring AMI but short of significance were found on the BDI, SCL-90 Psychoticism, and IMPS Excitement factors. The SCL-90 Psychoticism factor contains several items common to depression (e.g., the idea that you should be punished for your sins, or feeling lonely with other people) while IMPS Excitement highlights arousal behavior (e.g., loud, overactive, hurried speech), perhaps responsive to the sedative effects of AMI.

Randomization resulted in no significant differences in severity or polarity factor scores across the three medication groups at baseline (Table 2). Following treatment, patients in the HAL group improved significantly more on the composite severity measure than those receiving AMI or PLC, with no difference between AMI and PLC. Post-treatment polarity factor scores reflect a trend toward differences among groups attributable to an increase in affective polarity in the PLC group and a decrease in affective polarity among patients treated with AMI. These effects are independent of severity.

In the comparison of severity and polarity factor scores by borderline subtype, increased severity is attributed to the mixed BPD/SPD group while increased affective polarity is associated with the pure BPD patients (Table 3). There was no significant interaction of medication group with polarity of symptom pattern (affective vs. schizotypal) on overall severity, leaving unsupported the hypothesis of significant differential efficacy

TABLE 2

Medication Effects on Severity and Polarity Scores[a]

[a] *N* decreased by six cases with inadequate data to compute factor scores (2 AMI, 1 HAL, 3 PLC).

[b] Pretreatment Severity as Covariate

Posttreatment Severity: HAL vs. PLC (*F* 5.782, *p* .022); AMI vs. PLC (*F* 0.713, n.s.)
AMI vs. HAL (*F* 3.974, *p* .054).

[c] Pretreatment Polarity, Posttreatment Severity as Covariates

Posttreatment Polarity: HAL vs. PLC (*F* 2.547, n.s.), AMI vs. PLC (*F* 6.687, *p* .015)
AMI vs. HAL (*F* 0.481, n.s.)

of medication by affective or schizotypal dimensions. Analysis of medication effect by borderline subtype produced similar results. There was no significant interaction of medication group with subtype diagnosis (BPD vs. BPD/SPD) on overall severity. Using this statistical strategy, we were unable to demonstrate a pharmacologic behavioral dissection of medication responsive borderline subtypes. To identify unique effects of medication independent of severity, the severity scores were factored out in an ANCOVA. With composite severity "partialled out," significant medication effects remained in measures of hostility (IMPS, SCL-90) and paranoid ideation (SCL-90) suggesting a specific effect for HAL, and on the Additional Factor of the SCL-90, reflecting an antidepressant effect for AMI. The pattern of change over time was striking—with most improvement occurring by Day 21 (e.g., 7 days med-free followed by 2 weeks of medication). This is well illustrated in the Figure indicating the course of response over the study on the self-rated General Severity Index of the SCL-90.

[a] ANCOVA: Pretreatment severity, pretreatment polarity as covariates; higher score implies greater severity/more affective polarity.

Summary

Although these are preliminary results of a study in progress, several important observations arise from our data. Significant medication effects are found consistently in self-rated measures—not interview based ratings. The sensitivity and relevance of our interview based measures to specific borderline symptoms warrant further study. There is a need for measures of change more relevant to this disorder. We are unable to determine

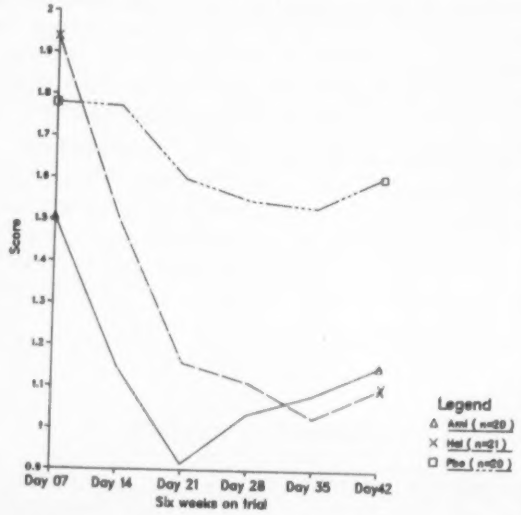

FIGURE. Comparison of SCL–GSI across three treatments.

if interviewer bias plays a role in minimizing reported effects, since expectation of clinical change is understandably modest given the degree of chronic impairment. Similarly, the interview setting may affect patients' willingness to report change.

The disappointing response to AMI in patients with strong depressive symptoms suggests that more attention be given to the atypical pattern of depressive presentations in borderline patients as a possible indication for future research with monoamine oxidase inhibitor antidepressants.

Despite these limitations, our preliminary results support the use of low-dose neuroleptics in borderline disorder and demonstrate significant efficacy against a broad range of symptoms including hostility, paranoia, anxiety, and depression. Despite the prevalence of affective symptoms in this population, AMI is no better than HAL against depression and little better than PLC against a wide range of associated borderline symptoms. Medication effects are modest in magnitude, generally attributable to decreased severity and occur early in the treatment course. Both unstable and schizotypal borderline patients demonstrate some improvement. We are unable to separate borderline subtypes by medication response or support the clinical prejudice predicting selective efficacy for HAL in schizotypal patients and AMI in unstable borderlines. Rather, we have shown that HAL is broadly effective while AMI adds little to the treatment of borderline disorder.

Open Trial of Buspirone in the Treatment of Major Depressive Disorder

Edward E. Schweizer, M.D.,[1] Jay Amsterdam, M.D.,[1] Karl Rickels, M.D.,[1] Myron Kaplan, D.O.,[1] and Marian Droba, M.D.[1]

The pharmacologic treatment of depression and anxiety rests on the clinical judgment, often difficult to make, as to which diagnosis is primary. Confidence in the essential therapeutic importance of this decision has been undermined recently by studies suggesting anxiolytic properties for antidepressants (Klein, 1964; Sheehan et al., 1980), and antidepressant properties for benzodiazepines (Rickels et al., 1985). Buspirone is a newer anxiolytic with a novel chemical structure and an atypical profile of pharmacologic activity (Riblet et al., 1982). It has demonstrated an anxiolytic efficacy comparable to the benzodiazepines (Goldberg & Finnerty, 1979; Rickels, 1981), despite having no apparent activity at the Bz-GABA receptor. The side-effect profile of buspirone, at doses in the anxiolytic range of 15 to 30 mg, compares favorably with benzodiazepines, with significantly less sedation (Newton et al., 1982).

Several studies (Feighner et al., 1982; Goldberg & Finnerty, 1979) using buspirone in anxious patients have noted concomitant improvement in associated depressive symptoms. This led us to undertake an open-label study of the efficacy of buspirone in major depression.

Methods

Thirty patients meeting DSM-III (Diagnostic and Statistical Manual—3rd ed., 1980) criteria for Major Depressive Disorder were entered in an open-label treatment protocol. Eligibility criteria required a score of at least 18 on the Hamilton Depression Scale (HAM-D), and at least 9 on the Raskin Depression Scale, with the Covi Anxiety Scale scoring less than the Raskin scale. Excluded from the study were patients with personality disorders, organic brain syndrome, schizophrenia, alcohol, drug abuse, or acute or unstable medical conditions. Also excluded were pregnant or lactating women, or women of child-bearing potential not taking birth control precautions. Concomitant medications were not permitted. A 1-week, single-blind placebo washout was employed prior to entry into a 4-week acute treatment phase. Initial dosing with buspirone was begun at 15 or 30 mg, given on a three-times-a-day (t.i.d.) schedule. Dosage adjustments were made every 3 to 4 days to a maximum dose of 90 mg, as tolerated by the patient and in light of clinical indications. At the end of 4 weeks' acute treatment, the patient had the option of entering a 3-month maintenance phase.

Participation in the study was voluntary and written informed consent was given. Table 1 shows the clinical characteristics of the patients. Notable are the duration of current illness, which averaged over 1 year for both melancholic and non-melancholic subtypes;

also the fact that most patients had had more than one previous trial of antidepressant treatment. Ten patients met melancholic criteria while 20 were non-melancholic. At intake, the mean HAM-D score for melancholics was 28.1±3.5, and for non-melancholics, it was 20.6±3.6. Weekly HAM-D, Hopkins Symptom Checklist, and a 6-point physician- and patient-rated global improvement scale were used to assess treatment outcomes.

Results

Of the 30 patients entering treatment, 18 completed the 4-week acute phase (3 melancholic and 15 non-melancholic). As indicated in Table 2, attrition was higher for the melancholic than for the non-melancholic group. Lack of therapeutic effect was most frequently cited as the reason for drop out.

Table 3 indicates percentages of patients reporting a given side effect. Overall, 11 patients complained of none or mild side effects and 19 complained of moderate to severe side effects. These figures must be understood in light of a dosing strategy that, in the absence of a known antidepressant dose range, called for incremental increases to 90 mg, or until significant side effects developed, whichever came first. As a result, the mean maximal dose for buspirone was 78 mg, which was well above the usual anxiolytic range. In retrospect, a dose of 40 to 60 mg appeared sufficient to produce the desired antidepressant effect and was well tolerated.

Table 4 gives the results for physician rated global improvement at the end of acute treatment. Moderate to marked improvement was seen for 55% of non-melancholic depressives as opposed to none of the melancholics. This is a significant treatment effect for non-melancholics (moderate and marked improvement vs. mild, none) at $p < .05$. There was virtual identity between patients evincing moderate to marked improvement, and those deciding to continue the trial of buspirone into a maintenance phase.

Tables 5 and 6 show the HAM-D scores for melancholic vs. non-melancholic patients at each of the study weeks, presented in two different ways. Table 5 presents "endpoint" data in which final HAM-D scores of dropouts are carried forward to final Week 4. This corrects for the artifactual improvement in HAM-D scores that results from deleting dropouts, who frequently have higher scores

TABLE 5

Weekly Endpointer HAM-D Scores (Mean ±SD)

and have failed to respond to treatment. To counterbalance this approach, Table 6 presents weekly HAM-D data on "completers" of the 4-week active treatment protocol. Repeated measures analysis of variance, conducted on endpoint and completer data, demonstrated a significant improvement in HAM-D scores over the 4 weeks of the study for the non-melancholic, but not the melancholic, subgroup.

To address the question of whether baseline levels of anxiety would predict treatment response, baseline Covi anxiety scores were examined in treatment responders vs. nonresponders. As can be seen (Table 7), baseline levels of anxiety were not significantly different for treatment responders vs. nonresponders.

Conclusion

A preliminary study of buspirone in the treatment of DSM-III Major Depression suggests a significant antidepressant effect for this novel compound for a non-melancholic subgroup. Further, antidepressant efficacy did not appear to be merely the result of an anxiolytic "halo" effect, since treatment response was not predicted by baseline levels of anxiety or its reduction. A daily dose in the range of 40 to 60 mg of buspirone appears sufficient to produce an antidepressant effect. The open-label nature of the study obviously makes any conclusions highly tentative. But given these preliminary results, and the favorable side-effect profile, a well-controlled, double-blind trial of buspirone in the treatment of non-melancholic depression would appear to be indicated.

TABLE 7

Baseline Anxiety

Depression Subtype	Treatment Response	Covi Score
Melancholic (*N* = 10)	Nonresponders	7.8
Non-Melancholic (*N* = 11)	Responders	5.9
Non-Melancholic (*N* = 9)	Nonresponders	6.0

A Review of Controlled Studies of Adinazolam Mesylate in Patients With Major Depressive Disorder

John P. Feighner, M.D.[1]

Introduction

At the NCDEU Annual Meetings in 1982 and 1984, some results of the dose-finding studies with adinazolam mesylate (DERACYN® Tablets, The Upjohn Company) in depressed patients, and two subsequent placebo-controlled antidepressant trials using the new triazolobenzodiazepine, were presented. Since then, a total of five studies controlled with placebo have been completed, and four larger studies controlled with both placebo and an active standard have also been completed or nearly completed. The latter were 6-week trials comparing adinazolam with imipramine in depressed outpatients and with amitriptyline in depressed inpatients. The purpose of this paper is to review the clinical data obtained in these Phase II and III trials.

In animal studies using assays known to predict anxiolytic activity, e.g., pentylenetetrazol antagonism, adinazolam was effective at doses similar to those for diazepam (Hester et al., 1980). Yet, in assays known to predict antidepressant activity, e.g., yohimbine toxicity potentiation, adinazolam was effective at doses similar to those for imipramine (Hester et al., 1980). Works by others also indicate that adinazolam shows typical antidepressant-like activities in animals. For instance, in rats, adinazolam inhibited reserpine-mediated upregulation of cortical β-adrenergic receptors (Lahti et al., 1984) and sensitized forebrain hippocampal neurons to applied serotonin (Turmel & deMontigny, 1984). The apparent key to the novel dual activity was the addition of a tertiary amino group to the 1-position of the triazolobenzodiazepine ring system.

The first clinical trials with adinazolam were done in patients hospitalized for severe depression. These trials indicated antidepressant activity with little or no anticholinergic activity. Perhaps greater novelty, however, rested in the rapidity of the responses. About half those responding to adinazolam responded markedly within 2 to 7 days after starting the new drug (Pyke et al., 1983).

Methods

The five Phase II double-blind, placebo-controlled studies with adinazolam were conducted in patients with DSM-III Major Depression. The two inpatient studies required a total score of greater than 25 on the 21-item Hamilton Rating Scale for Depression (HAM-D); the three outpatient studies required HAM-D scores greater than 20. In all five studies, patients had to be more depressed than anxious on Raskin and Covi scores, respectively.

The Phase III double-blind, placebo- and tricyclic-controlled studies also treated DSM-III Major Depression. Three studies required outpatients with HAM-D total scores of greater than 19; one study required inpatients with Melancholia and HAM-D total scores greater than 25.

Patients under age 18 or over age 65 were excluded, as were women not using reliable contraceptive methods. Patients with uncontrolled physical illness or those taking concomitant psychotropics, patients with a history of substance abuse or benzodiazepine sensitivity, and patients who had been treated with electroconvulsive therapy or investigational drugs within a month of the study were excluded. Patients with DSM-III diagnoses of bipolar, dysthymic, or atypical depression were also excluded, but bipolar II subjects

---

[1] Feighner Research Institute, La Mesa, CA 92041.

(atypical bipolar major affective disorder) were allowed in one Phase II outpatient study (6310, Dunner).

Study Design

During screening, for which up to 7 days were allowed, a placebo was given three times a day while physical examinations and diagnostic workup were completed. Patients who fulfilled entrance criteria were then randomized to receive either adinazolam or placebo tablets for 6 weeks. In Phase III studies, an additional group of patients received either imipramine (outpatients) or amitriptyline (inpatients).

Follow-up evaluations were conducted on day 3 or 4 and at weeks 1, 2, 4, and 6 after medication was initiated. Efficacy judgments were made on the basis of the rating scales shown in Tables 1 and 2. These included the HAM-D total score, the Physician's Global Impressions, and, at final evaluation, a Patient's Drug Evaluation Form. Tolerance was rated through a modification of the Treatment-Emergent Symptoms and Side Effects (TESS) Form (Guy, 1980). For analyses, all medical events were added to the TESS results.

Results

Phase II Studies

A total of 172 patients were treated with adinazolam and 171 patients were treated with placebo; of these, 164 adinazolam-treated patients and 158 placebo-treated patients completed more than 5 days of study medication and were considered evaluable. An analysis of patient enrollment and results by study is given in Tables 1 and 2. Except for study 6306 (Cohn), which predominantly enrolled males, female enrollees outnumbered males in Phase II by 64% to 36%.

Adinazolam (30 to 90 mg daily) was significantly superior to placebo on most or all measures in four of the studies (6306, Smith; 6309, Cohn and Feighner; 6310, Dunner), which cumulatively treated 140 patients with adinazolam and 140 patients with placebo. Of these, more than twice as many adinazolam-treated patients (63%) completed the 6-week study as compared with placebo-treated patients (31%). The predominant reason for dropping out was inefficacy of the placebo. The combined incidence of moderate or marked therapeutic effect at final evaluation in these four studies was 61% with adinazolam and 29% with placebo. The final incidence of 50% or greater decrease in HAM-D

total score was 60% with adinazolam and 28% with placebo.

The Figure shows the Physician's Global Impression of the therapeutic effect of the drug relative to length of treatment combining the two outpatient studies done under the same protocol (6309, Cohn and Feighner). Only those with a moderate or marked therapeutic effect are counted. By one-tailed Fisher's exact test, the difference between groups is already significant by day 2, the first follow-up evaluation. More than half of the eventual responders to adinazolam did so by day 4, and three-fourths, by day 7.

The only study not significantly favoring adinazolam on most measures was a study of 63 Veterans Administration Hospital patients, 32 given adinazolam and 31 given placebo (6306, Cohn). The results in this study were not significantly different for the two treatments except in response to the Patient's Drug Evaluation Form; significantly more patients (54%) who had taken adinazolam felt that the drug helped them moderately, much, or very much, as compared with patients who had taken placebo (25%).

Table 3 shows the side effects observed in 10% or more of the patients in either treatment group in the largest compilation made to date, that for studies 6306 (Cohn) and 6309 (Cohn and Feighner). The side effects reported at incidences higher with adinazolam than with placebo were mainly drowsiness, followed by lightheadedness, dizziness,

FIGURE. Number of patients with a Physician's Global Impression rating of moderate or marked therapeutic effect of the study drug.

or faintness; excessive dreaming was also more frequent with adinazolam than placebo, but only in one of the three studies. No hypomanic episodes, even in the bipolar II subjects, and no significant anticholinergic effects were observed.

Phase III Studies

Four 6-week comparisons with placebo and a tricyclic antidepressant, each with 40 subjects or more per treatment group, have been analyzed. Three single-center studies involved outpatients who were required to have DSM-III Major Depression and a HAM-D total score greater than 19; one multicenter study involved inpatients, required to have DSM-III Major Depression with Melancholia and a HAM-D total score greater than 25. The interim results from these Phase III studies are shown in Table 4.

In the outpatient studies, adinazolam (30 to 90 mg daily) was compared with imipramine (75 to 225 mg daily) and with placebo. Approximately 40 patients were enrolled per treatment per center; a majority of the patients enrolled completed the study in each treatment group at each center. Across the centers, the final incidence of moderate or marked therapeutic effect was 64% with adinazolam, 55% with imipramine, and 38% with placebo. The final incidence of 50% HAM-D total score reduction was 47% with adinazolam or imipramine and 30% with placebo.

The inpatient studies compared adinazolam (30 to 120 mg daily) with amitriptyline (75 to 300 mg daily) and with placebo in eight participating centers. Interim results with 54 patients given adinazolam, 46 given amitriptyline, and 41 given placebo, indicate that a majority of the patients completed treatment with adinazolam or amitriptyline (59% and 61%, respectively), but only 39% completed treatment with placebo. The incidence of moderate or marked therapeutic effect (50%, 56%, and 27%, respectively), that of HAM-D total score decrease to eight or less (30%, 33%, and 15%, respectively), and perhaps that of 50% symptom reduction on HAM-D (39%, 52%, and 27%, respectively), indicate that adinazolam is an effective antidepressant in severe depression, also.

The only side effects seen significantly more with adinazolam than with placebo in any Phase III study have been drowsiness and some confusion, decreased memory, etc., which were transient. Again, no significant anticholinergic effects were seen.

Discussion

In Phase II trials adinazolam was active as an antidepressant; it was superior to placebo in almost all measurements. It had a rapid onset of action, providing a significant antidepressant effect after 2 to 7 days in most eventual responders. Little dose titration was

[b] DSM-III diagnosis: Major depression with melancholia. Interim analysis across eight centers.

needed before the onset of efficacy (an initial dose of 30 mg daily was titrated to a final dose median of 45 to 80 mg daily).

Adinazolam alleviated the core symptoms of depression in these studies, as measured using HAM-D cluster scores, and it appeared useful in severe (inpatient) or moderate (outpatient) Major Depression, in chronic or relatively acute depression, and in drug-resistant depression. In addition, in studies done by Dr. David Dunner, 21 outpatients with bipolar II depression were given adinazolam with outcomes similar to those in patients with unipolar illness; none became hypomanic or manic. Since these were 6-week studies, only limited conclusions may be drawn regarding safety in bipolar II subjects.

Adinazolam was well-tolerated; the Phase II dropout rate for side effects was 4%, compared with 3% for placebo. The typical side effects observed were moderate and usually transient. Drowsiness was the most common and dizziness was the next most common. Anticholinergic effects were absent or equal to placebo. A tapered withdrawal period served to decrease side effects reported after extended use of benzodiazepines.

In the Phase III trials, interim analysis of the studies with larger enrollment appears to support the conclusion that adinazolam is an active antidepressant that is useful in both outpatients and inpatients. The side effects seen in Phase III were similar to those seen in the Phase II trials.

The overdose profile of adinazolam has so far been completely benign. Five suicide attempts using up to 500 mg produced no cardiovascular toxicity; in these patients cognitive impairment and oversedation were the only effects observed and these were rapidly reversible without neurologic sequelae.

In conclusion, adinazolam is a new triazolobenzodiazepine that appears to be an effective antidepressant, even for hospitalized patients with Major Depression with Melancholia. The therapeutic index of this drug appears to be extremely promising and warrants further study.

Acknowledgment: While my center performed two of these studies and is currently participating in a third, the other studies reviewed herein were performed under the supervision of Drs. G.C. Aden, S.C. Bhatia, J.D. Carman, J.B. Cohn, D.L. Dunner, W.E. Fann, R.H. Gerner, B. Hubbard, M. Morphy, E. Robins, W.T. Smith, S. Thein, and C.C. Weise. The editorial assistance of M.M. Wesley is also appreciated.

Chronic Depression: Demographic and Clinical Characteristics[1]

James H. Kocsis, M.D.,[2] Carlyle Voss, M.D.,[3] J. John Mann, M.D.,[2] and Allen Frances, M.D.[2]

Interest in states of chronic depression has recently been raised because of observations that these conditions may represent unrecognized and/or poorly treated forms of affective disorder (Weissman & Klerman, 1977), and do share clinical, familial, biological, and treatment response characteristics with acute or episodic affective illnesses (Akiskal et al., 1980, 1981; Kocsis et al., 1985; Rounsaville et al., 1980; Ward et al., 1979). Prior to 1980, patients having chronic depression tended to be seen as suffering primarily from personality disorders, and their chronic depression was viewed as an aspect of, or complication of, character pathology (Diagnostic and Statistical Manual—2nd ed., 1968; Schildkraut & Klein, 1975). Recently, Akiskal et al. (1980) proposed a reclassification of "chronic characterologic depressions" into two major subgroups, one which shares many features of typical affective disorders including response to antidepressant medication and a second, medication unresponsive type, with "unstable" personality disorders. An extension of this reconceptualization of chronic depressions was placement in DSM-III (1980), under the term Dysthymic Disorder, in the Affective Disorder section of that classification.

Chronic depression has been regarded variously as a complication of personality disorders, an attenuated form of affective disorder, or as a reaction to chronic stress (DSM-III, 1980). However, there have been few empirical studies which have reported data pertinent to these theories. Validation of meaningful subtypes of chronic depression along the suggested theoretical lines remains a goal of research.

The current study was undertaken for the purpose of systematic collection of data about concomitant affective and personality diagnoses, presence of psychosocial stressors, and family history of psychiatric disorders in a sample of patients with chronic depression and a comparison group of outpatients having episodes of acute depression.

Methods

Description of the Study: The study was conducted in two outpatient clinics (Department of Psychiatry, Maine Medical Center and Department of Psychiatry, New York Hospital-Cornell Medical Center) according to identical protocols and selection criteria. Patients were interviewed by research psychiatrists utilizing a semi-structured interview designed to elicit information which would allow diagnosis according to the DSM-III. Based on this interview, clinicians rated DSM Axis I, II (Personality Disorders), and IV (Psychosocial Stressors). Systematic inquiry about demographic material and family history of psychiatric disorders was also done and results were recorded at this time. Clinical symptom profile and severity were rated by use of the 24-item version of the Hamilton Scale for Depression (HAM-D; 1960). Information about prior treatments with psychotherapy or drugs was recorded and informed consent was obtained from all subjects.

Selection of Patients and Depressive Controls: Two patient groups were sampled, both drawn from the Affective Disorders clinics of the New York Hospital or Maine Medical Center. The chronic depression patients were included if they met DSM-III criteria for Dysthymic Disorders, i.e., had depressed or dysphoric mood for longer than 2 years and at least three associated symptoms of depression. Presence or absence of current Major Depression or Melancholia was systematically determined but patients were included

whether or not they had these associated or superimposed conditions. Patients with nonaffective DSM-III Axis I diagnosis (e.g., schizophrenia, drug or alcohol dependence, or organic brain syndromes) were excluded, as were patients with severe chronic or acute medical illness.

The sample of acute depressive controls included 26 age- and sex-matched patients who participated in one of two outpatient psychopharmacology studies of acute depression in the Affective Disorders clinic of New York Hospital. All had durations of the current episode under 1 year. They received the same battery of diagnostic and clinical evaluations at baseline with the exception of the evaluation of family psychiatric history.

Results

Comparisons of demographic and clinical characteristics between patients with chronic depression and the acute depressive control group are shown in Table 1. Age and sex did not differ significantly between the two groups. Significantly fewer acute depressives had ever married.

Thirty-seven of 39 (95%) chronic depressives fulfilled DSM-III criteria for Major Depressive Disorder in addition to their Dysthymic Disorder, and 23 (59%) also met criteria for Melancholia. Forty-seven percent of depressives were rated as having an Axis II diagnosis. Personality disorder diagnoses included: Dependent (*N* = 9), Avoidant (*N* = 4), Narcissistic (*N* = 3), Schizotypal (*N* = 3), Compulsive (*N* = 2), and five others which were given once each.

Axis I and Axis II diagnoses were similar for the acute depressive controls. All had Major Depressive Disorder by definition, 73% met criteria for Melancholia, and 40% were given an Axis II diagnosis. Moderate to severe psychosocial stress tended to be more prevalent in the acute depressives (62% vs. 47%). There was no significant difference in severity of illness in the two groups as measured by the 24-item HAM-D total score.

By definition, all patients in the chronic depressive sample had durations of illness greater than 2 years. In fact, this group reported remarkable chronicity of their depression. Fifty percent stated that depression had been continually present for more than 10 years. The chronic group showed a trend for earlier age of onset, with 65% reporting onset prior to age 25, as compared to 42% of the acute depressives.

Profiles of clinical symptoms as rated on the HAM-D in the two patient groups are compared in Table 2. Although chronic and acute depressives had similar frequencies of most items, acute depressives had significantly higher frequencies of four symptoms: loss of productivity, general somatic complaints of fatigue and body pains, diurnal variation of mood with morning worsening, and feelings of worthlessness. A history of suicide attempts was found in 19% of chronic and 10% of acute depressives. Only one patient had a history of more than one attempt.

Systematic family history data was collected in the chronic depressive sample. Fifty-five percent reported a history of depression in a first-degree relative, and 11% reported a history of mania.

A significant difference was noted in history of prior psychiatric treatment between

chronic depressive and controls. Fifty percent of the acute depressives had received at least one prior adequate trial of antidepressant medication, compared to only 18% of chronic patients. Seventy-six percent of chronic depressives had received prior treatment by psychotherapy. No comparison data were available for acute depressives.

Discussion

We report results of a study of clinical and demographic characteristics in 39 outpatients with Chronic Depression (DSM-III—Dysthymic Disorder). A group of 26 patients with acute Major Depressive Disorder was used as a comparison group.

Thirty-seven of the 39 chronic depressives also fulfilled DSM-III criteria for Major Depression and 59% also fulfilled criteria for Melancholia. Therefore, in this sample of patients there was clearly a good deal of symptomatic overlap between chronic depression and typical acute affective disorders as defined in DSM-III. The relationship between chronic depression and affective illness is further emphasized by the few differences seen in these two groups in other clinical and demographic characteristic and similarities in profiles of symptoms. These results and the high incidence of affective illness reported by the chronic depressives in their first-degree relatives support the notion recently advanced by Akiskal (1983) and Akiskal et al. (1980, 1983) that many states of chronic depression seen in psychiatric outpatients may represent attenuated or alternative forms of typical, acute affective disorders. Our previously reported preliminary results from a placebo-controlled trial of imipramine treatment conducted in this same chronic depression sample also supports similarity to acute forms of depression (Kocsis et al., 1985).

Another issue which has been raised by Akiskal et al. is the relationship of Dysthymic Disorders to Bipolar Illness (1981). In our sample of chronic depressives we indeed saw a larger than expected family incidence of bipolar illness, and one of our patients did develop a possible episode of drug-induced hypomania. Further data will be needed to address the relationship between these disorders, but it appears that a subgroup of dysthymic patients may be "sub-bipolar."

It has previously been suggested that some forms of chronic depression may result from the chronic presence of severe psychosocial or other kinds of stress (Schildkraut & Klein, 1975). The current study found a nonsignificant trend toward more current psychosocial stress in the acute depressives. However, prior studies have found interactions between stress, chronicity of depression, and non-response to antidepressant medications (Akiskal, 1982; Kocsis et al., 1984). We have not yet accumulated sufficient data to address such interactions in our chronic depressive sample. Some anecdotal experience suggests that chronic depression related to severe psychosocial stress may be a particular indication for psychotherapy or a combined treatment. It remains to be determined whether a meaningful subgroup of chronic depressives exists having chronic stress, a distinct clinical picture, and differential response to treatment.

Because of a long history of interest in relationships between chronic depression and personality disorder and the possibility that some forms of chronic depression may represent either a class of or complication of personality disorders, we have also examined the frequency of Personality Disorders in the two groups. Axis II diagnoses were given in 47% of chronic depressives and 40% of acute depressives, a nonsignificant difference. Because personality characteristics are known to be markedly influenced in a state-dependent fashion by depression (Akiskal et al., 1983; Liebowitz et al., 1979), evaluation of personality diagnosis in depressed patients is fraught with uncertainty. There may, in fact, not be an excess of personality disorders in chronic depressions and the apparent association may have resulted from the presence of depression itself on a chronic basis. However, further evidence that these patients have been seen previously by health professionals as being characterologic rather than affective is provided by our findings that chronic depressives have received frequent prior psychotherapy and little prior adequate antidepressant drug therapy. This has obvious important clinical implications in light of the increasing evidence that a substantial proportion of chronic depressions may respond to antidepressant drugs (Akiskal et al., 1980; Kocsis et al., 1985; Rounsaville et al., 1980; Ward et al., 1979).

Self-Rating of Personality Characteristics and Their Relationship to Treatment Response in Recurrent Unipolar Depressives: A Pilot Study[1]

Ellen Frank, Ph.D.,[2] David J. Kupfer, M.D.,[2] David B. Jarrett, M.D., Ph.D.,[2] and Miriam Jacob, ACSW[2]

Introduction

In their review of the relationship of personality to affective disorders, Akiskal et al. (1983) point out that personality variables have been hypothesized to relate to affective illness in at least four ways: 1) as predisposing factors to affective episodes, 2) as modifiers of affective episodes, 3) as a complication of affective illness, and 4) as an attenuated expression of affective illness. These authors point out that the predisposing factors hypothesis suggests that personality pathology may be etiologic with respect to affective illness. When personality variables are considered as modifiers of affective episodes there is no etiologic speculation, simply the observation that personality characteristics may have an effect on clinical presentation, course, treatment response, and outcome. Personality pathology may also be viewed as a complication of affective illness; it may be either state-dependent (i.e., present during the episode), or it may represent either a short-term or long-term complication observed following the remission of affective symptoms. Finally, personality pathology may represent an attenuated expression of affective illness. In this view, both personality features and affective episodes are considered to be expressions of the same underlying genetic or constitutional endowment.

Study Design

When we began the Maintenance Therapies in Recurrent Depression Study, we had no particular bias as to which of these views might be correct. However, we thought it would indeed be important to measure characteristics of personality in the patients being studied. The design of the Maintenance Therapies in Recurrent Depression Study has been described in detail elsewhere (Frank et al., 1984). Briefly, however, the study involves acute treatment of recurrent unipolar patients who present in at least their third episode of major depressive disorder. Patients must have a single-rater Hamilton ≥15 and a Raskin of ≥7. Prior to entering the study, all patients are evaluated with respect to sleep electroencephalograph (EEG) and neuroendocrine parameters after a 2-week drug-free period. Self-report and interview measures of clinical state and social functioning are taken at that time; however, personality is not assessed at baseline. Acute treatment combines imipramine (150 to 300 mg) and Interpersonal Psychotherapy offered weekly for 12 weeks, biweekly for 8 weeks, and then monthly. Patients remain in acute treatment until they achieve a Hamilton of ≤7 and a Raskin of ≤5 for 3 consecutive weeks. At this time, sleep EEG and all night neuroendocrine studies are repeated and self-report measures of personality are administered. Patients then enter a continuation treatment phase of 17 weeks, during which their symptoms are expected to remain stable and no changes are made in the treatment regimen. Following this 17-week period, patients receive a third evaluation including sleep EEG, neuroendocrine, and personality measures. They are then assigned on a random basis to one of five maintenance treatments (*see* Figure) which are continued for 3 years or until the patient experiences a recurrence of illness.

Subjects

The present report is based on the first 95 patients to finish the first 16 weeks of the Maintenance Therapies in Recurrent Depression protocol. The patient group consisted of 23 males and 72 females with a mean age of 40.6 ±10.8 years. The average length of the index episode was 23 weeks and the median was 19 weeks. Typically, age of onset was young (mean = 27.2±9.8 years; median = 24.0 years). Although the protocol requires only two previous episodes, the mean number of prior episodes was 6.1±5.8 and the median was 4.0. As we have reported elsewhere (Frank et al., 1984), a little over one third of the patients entering the Maintenance Therapies study have the expected treatment response. That is, they achieve remission within the first 7 to 8 weeks and remain well throughout the continuation period. A second third shows a more variable response, taking up to 16 weeks to achieve a stable remission. Finally, one third of the patients studied show only a partial response to the combined pharmacotherapy/psychotherapy treatment regimen. An algorithm was developed for assigning patients to these response categories on the basis of absolute Hamilton scores and percent change in Hamilton scores from baseline (Frank et al., 1984). When these three treatment response groups were examined, no differences were observed among them on age, sex, length of index episode, age at onset of illness, or number of previous episodes of affective illness. However, differences were observed in terms of baseline biological characteristics with the normal responders showing the most biological disturbance.

When we examined this larger cohort of 95 patients, we continued to observe the same kinds of differences between normal and slow responders in terms of sleep EEG and neuroendocrine changes. The present paper focuses on the differences in self-ratings of personality between the normal ($N = 35$) and the slow ($N = 32$) responders, and on the relationship between biological variables measured prior to treatment and personality variables measured once remission was achieved. The Hirschfeld-Klerman Personality Battery, a 436-item self-report inventory made up of a total of 17 scales taken from the Guilford-Zimmerman Temperament Survey, the Interpersonal Dependency Inventory, the Lazare-Klerman-Armor Personality Inventory (short version), the Maudsley Personality Inventory, and the Ego Control and Ego Resiliency Scales of the Minnesota Multiphasic Personality Inventory (MMPI), was used to assess personality.

Results

Since we had obtained personality ratings on patients at both Evaluation II (end of the 3-week stabilization period) and Evaluation III (end of continuation treatment) which, by design, are separated by 17 weeks, we examined the stability of scores on the Hirschfeld-Klerman battery over that time period.

TABLE 1

Hirschfeld-Klerman Battery:
Normal Versus Slow Responders

$^{*}p<.05$
$^{***}p<.001$

Abbreviations: GZTS = Guilford-Zimmerman Temperament Survey
IDI = Interpersonal Dependency Inventory
LKA = Lazare-Klerman-Armor Personality Inventory
MPI = Maudsley Personality Inventory

Test-retest correlation coefficients for the 17 scales ranged from .61 to .86, all $p<.001$.

When we compared normal responders with slow responders in terms of their personality characteristics, we found that on 7 of the 17 scales, normal responders showed significantly less personality pathology than did the slow responders. On no scale was the reverse true; the remaining 10 scales revealed no statistically significant differences between the two response types (*see* Table 1).

When comparisons were made between baseline biological characteristics and scores on the Hirschfeld-Klerman battery once patients had achieved remission, a complementary pattern emerged. Table 2 illustrates this pattern of relationships, indicating a dissociation between biological pathology and personality pathology.

Discussion

These pilot data suggest four preliminary conclusions. First, among outpatients with a history of recurrent unipolar illness, personality variables appear to remain relatively stable when the affective illness is in remission. Second, there appears to be a striking dissociation between biological disturbance (as measured when the patient is acutely ill) and the personality disturbance (as measured in remission). That is, the more disturbed the patient's baseline biology the less disturbed the patient's personality, and vice versa. Third, when recurrent unipolar patients are offered combined pharmacotherapy and psychotherapy as an acute treatment, those who show a relatively rapid response appear to have clear-cut biological disturbance, at least in terms of EEG sleep and neuroendocrine parameters, and little personality disturbance. Those who respond relatively slowly to this treatment regimen have little biological disturbance and considerably more personality pathology. Finally, with respect to the four hypotheses of Akiskal et al. (1983), whatever else personality may be, it does appear to function as a modifier of the affective episode in terms of the rapidity of response to combined pharmacotherapy/psychotherapy.

These preliminary studies suggest a number of interesting directions for further exploration. First, it would seem to be important to explore the personality characteristics of that group classified as partial responders, keeping in mind that this group needs to be subdivided further into those patients who ultimately went on to have a rapid response

to another treatment regimen (typically monoamine oxidase inhibitors) and those patients who, after being tried on several treatment regimens, continued to show only partial remission of their symptoms. Second, it will be important to explore the clinician ratings of personality features collected using the Personality Assessment Form at the same evaluation points as those used to administer the Hirschfeld-Klerman battery. Third, since the Maintenance Therapies in Recurrent Depression protocol also includes the evaluation of significant others using von Zerssen Personality Inventory (in press), it will be possible to examine the relationship between personality characteristics as perceived by a patient's significant other and the patient's biology and response to treatment. The questions of greatest interest, however, are how these biological and personality parameters might influence the risk of recurrence in a population at high risk for another affective episode and how each of these parameters interact with each of the five maintenance treatment conditions being studied. The answers to these final questions will have to await the completion of the 3-year maintenance phase.

The Suicide Assessment Scale: A Scale Evaluating Change in Suicidal Behavior[1]

Barbara Stanley, Ph.D.,[2,4] Lil Träskman-Bendz, M.D., Ph.D.,[3] and Michael Stanley, Ph.D.[4]

Introduction

Evidence increasingly points to a biochemical deficit associated with suicidal behavior (Åsberg et al., 1976; Stanley et al., 1982). As this body of evidence grows, it becomes more likely that pharmacologic studies designed to alter suicidal behavior will be conducted. In order to perform these studies, adequate means of evaluating change in levels of suicidality must be utilized. However, available measures of psychopathology and suicidality are inappropriate in this regard. There are several reasons for this lack of suitability. First, existing scales (Beck et al., 1979) focus principally on suicide ideation only. For treatment studies, it is vital that evaluation be linked to more than ideation, since ideation relies solely on verbal report. Suicidal thoughts can be denied or distorted and, thus, a rating that relies only on the patient's report can be faulty. While scales measuring other forms of psychopathology may have similar problems, this problem is particularly acute in assessing suicidality where patients may have greater motivation to conceal suicidal thoughts than other forms of symptomatology.

In addition to scales which evaluate suicidal ideation, another group of scales focuses on the prediction of suicide (Zung, 1974). These scales seek to identify individuals at risk for committing suicide and often combine demographic information with an assessment of psychopathology. These measures are also unsuitable for pharmacologic treatment studies because they focus on identification of future behavior. For purposes of treatment studies, current status and fluctuations in this status over time are of prime importance.

Some of the more widely used suicide scales which, while valid in many settings, would be limited in pharmacologic studies, include the following:

1. Scale of a Suicidal Ideation (SSI) (Beck et al., 1979)—This is a 19-item rating scale designed to assess suicidal ideation and includes items such as the wish to die;
2. Suicide Intent Scale (SIS) (Beck et al., 1974a)—This is a 20-item scale designed to characterize and describe a suicide attempt;
3. Index of Potential Suicide (IPS) (Zung, 1974)—The IPS is a 50-item scale combining psychopathology ratings with an index of level of social support to predict suicide potential;
4. Hopelessness Scale (Beck, 1974b)—This is a 20-item scale designed to evaluate pessimism in outlook toward life;
5. Reasons for Living Inventory (Linehan, 1983)—This is a 48-item scale which identifies reasons that individuals have to prevent them from committing suicide. It has been shown to differentiate suicide attempters from non-attempters.

An alternative to using suicide ideation scales would be to consider suicidal behavior as a symptom of a larger diagnostic entity. In most traditional psychiatric conceptualizations of suicide, suicidal ideation is viewed as a manifestation of depression. In this case, standard scales for depression treatment studies such as the Hamilton Depression Scale (HAM-D) (Hamilton, 1976) could be used. However, since both epidemiological and biochemical studies of suicide appear to point to a deficit that cuts across diagnoses

(Robins, et al., 1954), diagnosis-linked scales would be of only limited value.

Given that available scales were inappropriate for suicide treatment studies, the Suicide Assessment Scale, a scale assessing suicidality and related factors, was developed. Several criteria were established for this scale: 1) it was to evaluate both observable and reported symptomatology associated with suicidality; 2) the scale would not be linked to a specific diagnosis or weighted more heavily toward one diagnosis; and 3) the scale would be designed to evaluate current levels of suicidality and would be sensitive to change in suicide-related symptoms.

Method and Results

Scale Description

The Suicide Assessment Scale (SAS) contains 20 items each rated on a 5-point Likert-type scale. The ratings are performed in the course of a semi-structured clinical interview similar to an interview for the Brief Psychiatric Rating Scale (BPRS) (Overall & Gorham, 1976). The interview requires approximately 20 to 30 minutes to conduct. The items were developed by reviewing the relevant literature on differentiating suicidal and non-suicidal individuals. In addition, the authors of the scale independently generated items. Those items on which there was agreement among the raters as well as the literature were included in the scale. The scale items tend to be grouped in five areas: affect, bodily states, control and coping, emotional reactivity, and suicide thoughts and behavior. Table 1 shows the items on the scale.

Items 16 through 20 are the suicide ideation and behavior items. Item 1: sadness and despondency, Item 2: hostility, Item 9: anxiety, Item 12: low self esteem, conceptualized as a sense of failure, and Item 13: hopelessness are the items related to affect. Items 3: anergia, 8: tension, and 10: somatic concern are the bodily states items. Emotional reactivity is evaluated on items 4: hypersensitivity, 5: emotional withdrawal, and 14: inability to feel. The last grouping of items clusters around control and coping. These items are resourcefulness (6), perceived loss of control (7), impulsivity (11), and poor frustration tolerance (15).

Scale Development

In evaluating interrater reliability for total SAS scores, correlations among three raters (two for each patient evaluation) on a set of 37 ratings were computed. Interrater reliability was found to be adequate ranging from .78 to .88. In attempting to examine the validity of the SAS, we administered the scale to a group of 62 suicide attempters and 47 non-attempters who were hospitalized on a psychiatry service (Table 2).

The groups were matched for age and education. We had a higher proportion of males in the non-attempter category, principally as a consequence of the patient population at the time of data collection. Diagnosis did not differ significantly between the groups.

In examining the construct validity of the SAS, a comparison of scores for suicide attempters and non-attempters was made (Table 3). The results show suicide attempters scored significantly higher than non-attempters.

Table 4 differentiates between attempters and non-attempters on the other scales administered. The SSI, the HAM-D Scale, and the suicide item which assesses current suicidal state on the Hamilton Scale distinguished attempters from non-attempters. The BPRS and the Hamilton Anxiety (HAM-A) scale did not.

Table 5 shows the SAS scores for the three diagnostic groups represented in the study: Major Affective Disorder, Schizophrenia, and Personality Disorder. The diagnostic groups do not differ in SAS scores. This is consistent with the finding that suicide cuts across psychiatric diagnoses. Table 6 shows the correlation of the SAS with other scales. As can be seen, the SAS correlates moderately with depression as reflected by the HAM-D scores and moderately with suicide ideation as reflected by the SSI and the suicide item on the HAM-D. The scale shows somewhat of a correlation with psychotic symptomatology as measured by the BPRS. Furthermore, we find that the presence of suicide ideation within the past week and recent attempt in the past 6 months correlates with SAS scores.

TABLE 1

Suicide Assessment Scale

Item	Symptoms
1. Sadness and Despondency	Sad mood; low spirits; feels miserable
2. Hostility	Hostile; angry; belligerent; antagonistic; provoked to rage; easily provoked
3. Anergia	Lack of energy; weariness; tired; fatigued; worn down; harried; sense of weakness
4. Hypersensitivity	Sensitive to criticism; easily hurt; feels easily rejected; easily offended; touchy; takes things personally; suspicious; distrustful
5. Emotional Withdrawal	Lack of emotional contact; socially isolated; retreating; insulated; distrustful
6. Resourcefulness	Inability to solve problems effectively; lack of flexibility in coping with problems; sees few options and alternatives
7. Perceived Loss of Control	Feels lack of control over self or own destiny; feels at mercy of external events; feeling of lacking influence over environment
8. Tension	Physically tense; nervous; ill at ease; inability to relax; jumpy (exclude autonomic symptoms)
9. Anxiety	Worry; overconcern for present or future; fearfulness; dread; uneasiness (exclude autonomic symptoms)
10. Somatic Concern	Concern over physical health; preoccupation with physical symptoms (including aches and pains; sleeplessness; gastrointestinal and cardiovascular symptoms); generalized worries or delusions about body
11. Impulsivity	Acts on impulses; acts without planning or considering consequences; has irresistable urges; acts on spur of moment
12. Low Self Esteem	Low self esteem; feelings of worthlessness and inferiority; feels like a failure
13. Hopelessness	Feels hopeless and despairing; gloomy outlook; pessimistic; feels that the worst will happen; nihilistic thoughts
14. Inability to Feel	Depersonalization; lack of feelings; inability to feel emotions (not lack of empathy)
15. Poor Frustration Tolerance	Easily frustrated or irritated; readily discouraged
16. Suicidal Thoughts	Preoccupied with suicidal thoughts; thinks about being dead; thinks of reactions of others to suicide; finds it difficult to think of anything other than suicide
17. Purpose of Suicide	Suicide is a solution to the problem; suicide is the only alternative to problems; wants to relieve others of burden; reunion with someone who is deceased (as opposed to suicide attempt as attention-seeking and manipulative)
18. Wish to Die	Strong desire to die; feels that he/she doesn't deserve to live; feels that life isn't worth living
19. Lack of Reasons for Living	Feels that there is no one to live for; feels that no one cares; feels that there is no purpose to life
20. Suicidal Actions	Actively plans method for committing suicide; has written a note or informed others; needs to be supervised to prevent attempt

TABLE 2

Demographic Characteristics of Suicide Attempters and Non-Attempters

	Suicide Attempters ($N = 62$)	Non-Attempters ($N = 47$)	Significance Test^a
Age $\bar{X}$	33.1 ± 10.5	30.3 ± 7.6	1.53^{NS}

*$p < .05$
NS = Nonsignificant

Lethality and seriousness of the most recent attempt did not correlate with SAS scores nor did the level of aggressive behavior in the patient's past.

Table 6 shows the decline in SAS scores for a group of 8 suicidal patients who took part in a study using fenfluramine to treat suicidality. Although not a significant decline, possibly due in part to the small sample size, it appears that the scale will be sensitive to change and can reflect the effect of drugs on patients' conditions.

Discussion

The SAS is a measure that is designed to assess changes in level of suicidality for use in pharmacologic studies as well as other studies of suicidal behavior. The SAS may be useful to investigators studying suicidal behavior when it is important to use a rating that evaluates observable as well as reported symptomatology. The inclusion of observable symptoms on a suicide rating scale is particularly important for inpatient studies of suicidal behavior because suicidal ideation can be readily denied. Patients in psychiatric hospitals may be more motivated to deny suicidal thoughts than other psychiatric symptoms, since hospital privileges (e.g., passes) are often linked to a lack of suicidal ideation.

Furthermore, the development of the SAS represents an effort to identify and assess symptomatology associated with suicidal behavior (e.g., impulsivity and poor frustration tolerance) that go beyond suicidal ideation and diagnosis-specific symptoms. This effort parallels other scales that are commonly used in pharmacologic studies. These scales include the BPRS and the HAM-D and HAM-A scales.

The present study reports preliminary findings on the utility and validity of the SAS. Findings indicate that a high degree of reliability can be achieved in overall ratings. Furthermore, the scale appears to have construct validity, in that it correlates with suicidal ideation. In addition, those patients who have previously attempted suicide and are not cur-

rently suicidal tend to obtain somewhat higher scores on the SAS. This difference between those with and without a history of a suicide attempt may indicate that the scale is detecting some behavioral trait difference between suicide attempters and non-attempters. It may also be that patients with a previous history of a suicide attempt may be more likely to be hospitalized again for suicide-related reasons although not currently suicidal. While these speculations may be valid, additional research needs to be conducted to determine the reasons for the difference between those with and without a history of a suicide attempt.

In addition, several other analyses need to be performed on the scale to determine its usefulness. First, a large-scale follow-up study of suicidal patients over the course of their hospitalization should be performed. This analysis will determine whether the scale reliably detects changes in suicidality.

Secondly, a factor analysis of the scale items is yet to be performed. While the scale has been grouped by item clusters on an a priori basis, a factor analysis is required to determine whether the statistical analysis yields the same factor grouping.

The data for these analyses are in the process of being collected and, thus, the current findings on the SAS are preliminary. At this point, the SAS appears to be a promising instrument for use in evaluating the efficacy of pharmacologic treatments of suicidal behavior.

A Retrospective Clinical Analysis of the Overall-Rhoades Classification of Hamilton Depression Scale Profiles

Robert H. Lenox, M.D.,[1] Lelon A. Weaver, Ph.D.,[1] James E. Shipley, M.D.,[1] and Stephen Cohen, M.D.[1]

Introduction

Overall and Rhoades (1982a,b) described an empirical method of classifying depressed patients based on the profile of ratings on the Hamilton Depression Rating Scale (HAM-D). The profiles of 420 patients selected for participation in antidepressant medication trials were subjected to cluster analysis. Five phenomonological subtypes, designated "Anxious," "Suicidal," "Vegetative," "Paranoid," and "Somatizing" were identified. Discriminant functions were calculated to maximize the separation of the subtypes, resulting in five sets of weights for each Hamilton item. Classification was achieved by multiplying each Hamilton rating by these weights, summing algebraically within subtype, and assigning the patient to the subtype with the greatest positive sum. Rating profiles which result in only negative sums cannot be classified, i.e., the score profile does not fit any of the subtypes. No clinical validation data were included in their original publications.

The purpose of this study was to examine the distribution of the Overall-Rhoades classifications in the pre- and posttreatment data from depressed patients participating in clinical investigations of major depressive disorder. We examined two such groups of patients: an Inpatient population treated in our Clinical Research Center, and an Outpatient group followed in the ambulatory care setting at the University of Vermont College of Medicine.

Methods

Patients

The Inpatient group consisted of 24 patients, 7 males and 17 females, with an age range of 28 to 73 years; mean ±SEM = 53.8±3.0 years (Table 1). All patients were diagnosed as Major Depressive Disorder, Endogenous Subtype, in accordance with Research Diagnostic Criteria (Spitzer et al., 1977). This group was screened from a much larger sample of depressed patients referred for treatment to the psychiatric unit of a general hospital. All were returned to the community following treatment.

The Outpatient study group consisted of 13 patients, 4 males and 9 females, with an age range of 21 to 59 years; mean ± S.E.M. = 38.2±2.8 years (Table 1). These patients are selected from a larger group of physician and self-referrals. All were diagnosed as Major Depression according to DSM-III criteria. All patients completed the prescribed course of treatment without significant complications.

Measures

In both groups each patient was administered a battery of clinical assessment instruments. For our present purpose, the data for the pre- and posttreatment HAM-D and the

Physician's Global Impressions (PGI) scales will be considered. The latter instrument contains a 7-category scale (ranging from 1 = "Normal, not at all ill" through 7 = "Among the most extremely ill patients"). We have defined a patient as "Improved" if a final PGI rating of 1 or 2 ("Normal" or "Borderline ill") was given. In the Inpatient study, the ratings on both scales are the mean of two independent raters. The interrater correlations were +.91 for the HAM-D data and +.89 for the PGI. In the Outpatient study, all ratings on both scales were carried out by a single psychiatrist who did not participate in the Inpatient study and who was unacquainted with the Overall-Rhoades classification system.

Results

The first step was to determine the appropriate classification for each patient on the pre- and posttreatment Hamilton profiles according to the method detailed by Overall and Rhoades (1982b). Table 2 contains a sample output from our Inpatient group in which the highest positive score is underlined to indicate the category to which the patient was assigned. Thus, patient #629 was classified "Vegetative" during the pretreatment period and "Anxious" at posttreatment with an overall improvement of 67% in the HAM-D. On the other hand, patient #275 was classified "Suicidal" for both pre- and posttreatment with an overall improvement in the HAM-D of only 17%.

The results of the application of the method to our data are summarized in Table 3 which contains the distribution of the Inpatient and Outpatient groups across the six possible classifications for both the initial and final ratings. For ease of comparison, frequency data has been converted into group percentages. On the initial rating, the Inpatient group was heavily represented in the Vegetative and Suicidal classes with very modest frequencies in the other four categories. Following treatment, the final ratings showed a substantial increase in the Anxious and Not-Classifiable categories. These results are consistent with expectations for a group of moderately to severely ill patients, only some of whom responded to treatment.

For the Outpatient group, the initial (pretreatment) data showed a preponderance of patients classified in the Anxious category, some in the Vegetative, and a minor representation in the others; again consistent with expectations for a less severely ill group of patients. The final rating was heavily concentrated in the Not-Classifiable category, due largely to the reduction in the total HAM-D score and the substantial number of items rated zero.

A classification table using the Overall-Rhoades categories assigned to each patient for both initial and final Hamilton profiles was constructed. Each patient could be assigned to only one cell. In Table 4, the cell entries are the mean total Hamilton scale scores for the initial and final ratings of the Inpatient group. Each pair of entries represents a single patient. The table may be read as follows: The patient classified as Vegetative initially and Anxious finally had an initial Hamilton score of 30.0 and a final Hamilton score of 10.0.

There were 11 patients initially classified as Vegetative with a mean HAM-D rating of 30.1. At the time of final rating (posttreatment), 3 of the original 11 remained in the Vegetative category, while the others had shifted into Anxious (3) or Not-Classifiable categories (5). Here again, it is apparent that patients in the Inpatient study shifted from predominantly Vegetative/Suicidal/Somatizing categories pretreatment to Anxious/Not-Classifiable posttreatment. It is clear that those shifting into the Not-Classifiable category represented the patients showing the most improvement with a mean overall reduction in HAM-D of 81%.

Table 5 utilizes the identical format and contains the data for the Outpatient group. Three patients were initially classified as Vegetative with a mean HAM-D score of 24.8. Two of the three patients shifted into the Non-Classifiable category during the posttreatment rating with an overall reduction in HAM-D of 84%. As indicated in Table 2, the preponderance of patients were initially classified as either Anxious or Vegetative with the majority of these (77%) classified as Not-

Classifiable following treatment, with a mean score of 5.8.

Data shown in Tables 6 and 7 utilize the same format to show the initial and final PGI ratings for the Inpatient and Outpatient groups classified according to the Overall-Rhoades system. Patients were placed in the same cells as in Tables 4 and 5. A final rating that is underlined indicates that the patient was judged clinically "improved." Of the five patients in the Inpatient group classified as Vegetative or Suicidal both initially and finally, only one was rated as "improved" on the final PGI rating. Inspection of the HAM-D data (Table 4) for these patients indicated that this patient had the lowest final HAM-D rating, well below the mean of the other four patients. Similarly, only one patient initially classified as Vegetative and finally as Anxious showed significant improvement on the PGI, and the HAM-D rating reflected this improvement. Consistent with our findings in Tables 4 and 5, all patients found Not-Classifiable on the final HAM-D were found to be improved according to the PGI.

TABLE 3

Summary of Pre- and Posttreatment HAM-D Profile Classification by Groups

Overall-Rhoades Classification	Inpatient (*N* = 24) Initial	Inpatient (*N* = 24) Final	Outpatient (*N* = 13) Initial	Outpatient (*N* = 13) Final

Anxious	4	29	54	8
Not-Classifiable	4	42	8	76

(Cell Entries Are in Percent of Patient Groups)

As part of the design of the original inpatient study, the dexamethasone suppression test (DST) was administered to all patients pre- and posttreatment. Patients were administered the DST as described previously (Lenox et al., 1985). At the initial (pretreatment) period there were 11 suppressors and 13 non-

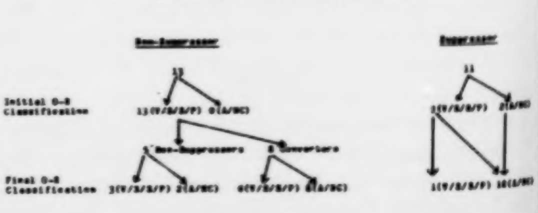

FIGURE. Flow diagram of changes in status on the DST as related to the Overall-Rhoades (O-R) classification system. Patients were administered the DST both during the pretreatment period (initial) and following at least 3 weeks of treatment (final). At the same time, HAM-D ratings were carried out and the O-R classifications were determined. (*See* text for definition of abbreviations.)

(Cell entries are the initial and final HAM-D ratings for each patient)

suppressors (*see* Figure). At the posttreatment (final) evaluation, of the 13 patients classified as non-suppressors pretreatment, 8 normalized while 5 continued to be non-suppressors. The 11 original DST suppressors remained suppressors at the final evaluation. For the purpose of examining the relationship of Overall-Rhoades classifications, we created two category groups, Vegetative/Suicidal/Somatizing/Paranoid (V/S/S/P) and Anxious/Not-Classifiable (A/N-C). It may be remembered that the Vegetative and Suicidal categories contain 19 of the 24 Inpatients classified during the pretreatment period. All 13 of the initial DST non-suppressors and 9 out of the 11 suppressors were found in the V/S/S/P categories while only 2 of the 24 fell into A/N-C group. Of the five patients designated DST non-suppressors posttreatment, 3 remained in the V/S/S/P classification and 2 in the A/N-C category. All 8 patients who normalized the DST posttreatment were in the A/N-C category. Of the 9 suppressors who were initially categorized in the V/S/S/P, 8 shifted into the A/N-C category at final posttreatment evaluation.

Discussion

First, it is important to point out that these data were collected as part of a psychopharmacological research program and hence cannot be regarded as a designed prospective validation study. Rather, it represents a retrospective study of the distribution of the Overall-Rhoades classification in pre- and post-treatment data from two groups of patients with diagnosis of major depressive disorder. Both Inpatient and Outpatient studies were carried out independently of each other and the Overall-Rhoades classification scheme.

We have noted several problems incidental to the Overall-Rhoades classification system which are worthy of discussion. It will be remembered that each HAM-D item rating is multiplied by a different positive or negative weight in each of the categories. The algebraically summed categories will thus be either positive or negative and the patient assigned to the category with the highest positive sum. But since the same item may have

TABLE 7

The Relationship Between the Overall-Rhoades Classification and the PGI Ratings for the Outpatient Group.

	Final							
	Vegetative	Suicidal	Somatizing	Paranoid	Anxious	Not-Classifiable	*N*	Mean
Vegetative	5/3					6/1 6/1	3	5.7/1.7
Suicidal						3/1	1	3.0/1.0
Somatizing						4/1	1	4.0/1.0
Paranoid							0	
Anxious	4/2				4/1	4/1 6/3 4/1 5/4 7/4	7	4.9/2.3
Not-Classifiable						6/2	1	6.0/2.0
N	2				1	10	13	
Mean	4.5/2.5				4.0/1.0	5.1/1.9		4.9/1.9

(Cell entries are initial and final PGI ratings. Underlining of final rating indicates patient was considered "improved") both positive and negative weights in the several categories, a patient rated high on several different items may cancel out the patterns, resulting in a high HAM-D total but fitting no specific category.

A still unresolved problem concerns the number of HAM-D items which are required to produce a valid categorization. The effectiveness of the discrimination of classification types depends upon the presence of both positive and negative weights; thus, if only a few items are non-zero rated, it is probable that no positive profile will emerge. Such a result, i.e., a finding of Not-Classifiable, is acceptable in logic, but a more serious question arises when a positive classification does emerge when only a few items are rated, since a chance combination of loaded items becomes more likely. This usually results when one or more of the rated items has a high positive loading in one category. Thus, even a rating of 1 on the HAM-D items #1 (Depressed Mood) and #4 (Early Insomnia) would ensure an Anxious categorization. Part of the problem is the dearth of negative offsetting scores when a large percentage of the items are rated zero. We have addressed these issues in this study by applying two decision rules:

1. If a profile results in "Not-Classifiable," it stands without regard to the number of items rated.
2. If a profile is categorized, the HAM-D must have at least one-third non-zero ratings for the categorization to be accepted as valid. If less than one-third of the items were rated, the profile was considered "Not-Classifiable."

The basic question is whether the Overall-Rhoades classification system results in clinically relevant data. Overall and Rhoades originally noted that the Vegetative type loaded onto items with symptoms of sleep disturbance, weight loss, and diurnal variation, consistent with endogenous features most responsive to somatic treatment intervention (tricyclics, ECT, etc.). The Anxious type is weighted for early (but not middle or late) insomnia, and psychic anxiety consistent with anxious depression or minor depression with anxiety, often responding to anxiolytics and thought to have a higher placebo response. The suicidal type was weighted heavily in the suicide item while the paranoid type was weighted heavily for paranoid symptoms and lack of insight. Both our Inpatient and Outpatient studies attempted to exclude psychotic depressions, but we would expect that the more seriously ill Inpatients would classify into the "sicker" categories, Vegetative and Suicidal. As shown in Table 3, 79% were so classified with high initial HAM-D (29.6) and PGI (5.2) ratings. Thus, the Overall-Rhoades classification did reflect the known severity of symptomatology in a carefully selected Inpatient group.

The Outpatient sample was not as severely ill as the Inpatient group since they were judged not to require hospitalization. There was a significant difference between the mean initial HAM-D scores of the Inpatient and Outpatient groups; 30.3 vs. 24.0, respectively. It is important to note that the same total score on the HAM-D can be produced by high ratings on different sets of items. From Table 3 it is apparent that this in fact occurred. Contrasting the Inpatient and Outpatient groups on the initial classification, the Vegetative and Suicidal categories comprised 78% of the Inpatient group but only 32% of the Outpatient group. For the Anxious and Not-Classifiable categories, the respective percentages were 8% and 62%. It can be concluded that the two groups of patients clinically judged to be different demographically (Table 1) and in degree of illness were differentially and properly categorized by the Overall-Rhoades classification.

Another question concerns the ability of the Overall-Rhoades classification scheme to reflect a change in clinical status. If a patient is judged to have improved significantly in terms of clinical criteria, this change should be reflected in posttreatment categorization. As noted in Table 3, the Inpatient group underwent a marked shift from Vegetative/Suicidal categories to Anxious/Not-Classifiable categories, with a similar shift occurring in the Outpatient group from Anxious to Not-Classifiable. The predominant shift in the Inpatient group would appear to be consistent with the suggestion of an affective spectrum, i.e., that patients with Vegetative/Suicidal depression profiles may pass through the stage described as an "Anxious Depression" prior to clinical recovery. These data might also suggest that some of the patients designated "Anxious" during pretreatment in the Outpatient study may represent an early stage of the Vegetative/Suicidal disorders treated in the Inpatient group.

Inspection of Table 4 shows that the final HAM-D rating of the patients remaining in the Vegetative/Suicidal categories did not differ from those moving into the Anxious category. Those moving into the Not-Classifiable category, however, had a significantly lower final HAM-D rating. There is, of course, an element of circularity present: patients with low HAM-D ratings are likely to fall into the Not-Classifiable category since there may not be enough non-zero item ratings to permit establishment of any pattern. However, inspection of the detailed PGI data of Table 6 confirmed the HAM-D data: all eight patients with a final classification of Not-Classifiable were judged "Improved" on the PGI scale. While it may be argued that since the HAM-D and PGI ratings were carried out by the same raters, agreement is only to be expected; cell-by-cell comparisons of the HAM-D and PGI ratings on the same patients showed numerous discrepancies.

It is concluded that the Overall-Rhoades classification reflects the clinical changes seen in both the HAM-D and PGI ratings. A shift into the Anxious category is not necessarily accompanied by a significant change in the HAM-D but movement into the "Not-Classifiable" is. Clinical improvement on the PGI is no more frequent in the Anxious category than in any other, but all patients rated "Not-Classifiable" showed significant clinical improvement. The data for the Outpatient group shows substantially the same trend.

We examined the possibility that the DST response might segregate according to the Overall-Rhoades classification scheme. Our findings would seem to indicate that patients classified into the "sicker" categories of Vegetative/Suicidal/Somatizing/Paranoid were as likely to be suppressors as non-suppressors. However, there was an indication that patients showing improvement by shifting into Anxious or Not-Classifiable categories were more likely to be the same patients whose DST converted to suppression. These data would be consistent with evidence showing a link between clinical improvement and DST conversion (Greden et al., 1980; Nemeroff & Evans, 1984). However, one must be cautious in light of our recent report that normalization of DST may be dependent upon long-term factors affecting the ability of the hypothalamic-pituitary-adrenal axis to revert to normal homeostatic control (Lenox et al., 1985).

In a recent study reported by Overall (1984), he examined the classification of patients enrolled in a series of 11 studies examining the clinical efficacy of nomifensine. Interestingly, while the initial classification type did not predict response reliably, it was apparent that patients in the Somatizing category appeared to be more responsive to placebo. However, the investigators did not study changes in classification profile as a function of treatment response.

The utility of the Overall-Rhoades classification scheme to prospectively screen and follow patients in psychopharmacological/behavioral/or even psychotherapeutic studies requires further investigation. These studies might address the early exclusion of placebo responders from major drug trials; the predictive value of suicidal classification; or the selection of patients more likely to respond to psychotherapy versus pharmacotherapy. Since the HAM-D is an instrument widely accepted and utilized in clinical studies, the potential application of this classification system requires further study.

Understanding the Response Lag to Tricyclics. I. Application of Pulse-Loading Regimens With Intravenous Clomipramine[1]

Bruce G. Pollock, M.D.,[2,3] James M. Perel, Ph.D.,[3] Michael Shostak, M.D.,[3] Seymour M. Antelman, Ph.D.,[3] Barbara Brandom, M.D.,[4] and David J. Kupfer, M.D.[3]

The slow, gradual therapeutic onset of tricyclic antidepressants (TCAs) is difficult to explain by their reuptake-blocking properties alone, because these effects occur acutely. Recent research on the mode of action of TCAs has focused primarily on chronic modification of rat postsynaptic β-adrenergic receptors manifesting decreases in density (Sulser, 1983) and dopamine autoreceptors displaying subsensitivity (Chiodo & Antelman, 1980). These time-dependent phenomena may help to explain the enigma of the therapeutic delay in antidepressant treatment. Conversely, the explanation might be pharmacokinetic. Retrospective analyses of plasma level/response data have revealed that optimal effects are observed within 5 days after attaining adequate steady-state levels of orally administered antidepressants (Perel, 1983). Furthermore, it has been found that continuous intravenous infusions of TCAs in rats produce β-receptor down-regulation within 16 to 48 hours as opposed to intraperitoneal (i.p.) or oral routes which produce changes after 10 days (Sethy & Day, 1985).

The variable, extensive hepatic pre-systemic clearance and relatively long half-lives of TCAs militate against the rapid achievement of therapeutically effective steady-state blood levels via the oral route. Intravenous (i.v.) medication circumvents this limitation and, in addition, provides an opportunity to test whether continuous medication is necessary after the administration of a sufficiently large initial dose. The relative contribution of pharmacokinetic versus pharmacodynamic factors in the therapeutic onset of TCAs was examined using a pulse-loading dose strategy with i.v. clomipramine (CMI). I.V. clomipramine is a commonly employed treatment in many European centers. Treatment, however, is typically initiated with 25 to 50 mg in a morning dose, and gradually increased to 150 to 200 mg over a 7- to 10-day period, with an attendant therapeutic lag, thereby precluding observations of more rapid onset of action. Pulse-loading may be defined as the rapid attainment of transient therapeutic plasma concentrations.

Methods

Those studied were inpatients on the Clinical Research Unit at Western Psychiatric Institute and Clinic. All patients had a minimum duration of their current illness of 2 weeks and a maximum current episode duration of 1 year prior to hospitalization. A psychiatric interview and physical examination were carried out at admission, and collateral information was obtained from the families and records of prior treatment. During a 2-week drug-free period, patients underwent routine tests, including blood chemistry, EEG, and EKG, and any other tests suggested by their history and physical examination. They were then evaluated by two independent psychiatrists to ensure criteria of the Diagnostic and Statistical Manual (3rd ed.) for either Major Depressive Episode with Melancholia or Bipolar Disorder, Depressed, were met. If patients met these diagnostic criteria and were not delusional, were physically

healthy, had a minimum rating of 15 on the 17-item Hamilton Depression Rating Scale (HAM-D) at the end of the 2-week drug-free period, and gave written informed consent, they entered the protocol.

An overview of the protocol is shown in the Table. EEG sleep and cardiac rhythm were recorded via remote cable while patients slept in their own rooms on 11 nights during the protocol. The first 2 nights of EEG sleep were considered as facilitating adaptation to the procedure while data for the next 2 nights were averaged and represent baseline sleep. EEG sleep was recorded on the nights of clomipramine or saline infusions and 7, 8, and 10 nights after the infusions and for 2 nights at the start of any additional infusions. All sleep records were scored independently without knowledge of the clinical diagnosis or drug status of the patient. In addition to the standard classification of sleep into stages, automated delta analyses were performed according to methods previously described (Kupfer et al., 1981a). Patients were rated by an independent observer with the HAM-D at the start of the protocol, the day following the second infusion of CMI or saline, and twice weekly thereafter.

On the fifth evening of the protocol, at 9:30 p.m., 75 mg of CMI diluted in 250 cc of normal saline was administered via a butterfly cannula. This procedure lasted approximately 45 minutes. The following evening 200 mg of CMI in 500 cc of saline was administered over a 90-minute period. No additional medication was given for 11 days. Ten patients completed the above protocol. Four patients received i.v. saline only, in a double-blind fashion, on protocol nights 5 and 6. These patients were then offered active CMI infusions on nights 11 and 12. A minimum of six timed plasma samples were taken up to 80 hours after the second CMI infusion for pharmacokinetic analysis and twice weekly thereafter. Plasma samples were analyzed by radioimmunoassay and high performance liquid chromatography using methods developed in our laboratory (Stiller et al., 1985). Pharmacokinetic treatment of plasma level data was performed utilizing curve fitting by our version of the computer program ESTRIP (Brown & Manno, 1978) for the Hewlett Packard 9836, followed by nonlinear regression analysis (Yamaoka et al., 1981). Half-lives were calculated using a modification of a program written by Niazi (1977). Paired *t*-tests and Wilcoxon's signed rank test (two-tailed) were used in the statistical analyses.

Results

One male and 9 females (mean age 40.6 s.d. ± 11.2 years) with an average duration of illness of 7.5 months, were admitted to and completed the protocol. The infusions of clomipramine were well tolerated. All patients experienced a pleasant sedation during these infusions, but were kept awake until the infusions were completed because of the sleep studies. Six patients experienced mild to moderate nausea on receiving the first infusion of 75 mg CMI, while 3 of these patients subsequently had milder nausea with the second infusion of 200 mg. Two patients experienced myoclonic jerks and 4 complained of a transient restlessness shortly after the initation of the infusions. Three patients complained of mild headache on the morning af-

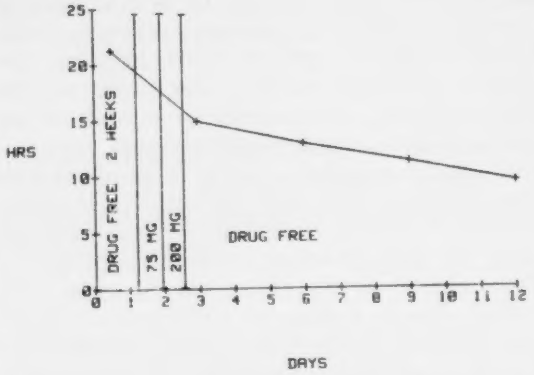

FIGURE 1. Mean Hamilton rating scale for 10 patients treated with IV clomipramine pulse-loading.

ter the second infusion. There was one report of blurred vision and three of dry mouth from patients receiving CMI, while 2 patients who received saline initially also complained of these side effects. Blood pressure remained stable throughout the infusions and there were no cardiographic changes post-infusion.

The HAM-D means changed over the course of the protocol as shown in Figure 1.

The mean HAM-D for the 10 patients just prior to the first CMI infusion was 21.5±SEM 2.8, as compared to 14.8±SEM 3.9 on the day (protocol day 7) following the second infusion ($p = .02$, Wilcoxon's signed rank test). Ten days after the second infusion of CMI (protocol day 16), the mean HAM-D had dropped further to 9.5±SEM 3.5 ($p < .02$ relative to protocol day 7). The immediate reduction in the HAM-D after the second infusion was primarily due to all patients reporting an improvement in their sleep. Eight patients, however, continued to report attenuation of their depressive symptoms over the ensuing 10 days. This progressive improvement occurred despite the fact that no additional medication was administered over this time. Only 2 of the 10 patients failed to clinically improve after the CMI infusions. Interestingly, one of these nonresponders became worse when sleep deprived for a pre-protocol EEG. At the conclusion of this study period, patients were placed on differing regimens of tricyclic therapy (either CMI or imipramine). Two of the 8 patients who had achieved near remission of their depression with i.v. CMI relapsed on oral CMI but improved again when lithium was added.

To control for the increased attention and nonspecific effects due to the procedures, 4 patients initially received two infusions of i.v. saline in a double-blind fashion. As shown by Figure 2, their mean HAM-D score slowly changed by 19% over a 10-day period following the second saline infusion. When these patients then received two CMI infusions, in an open fashion, their mean HAM-D score dropped rapidly by 43.4% within the ensuing 10 days.

Changes in EEG sleep were remarkable. The first REM period latency, after 2 weeks drug-free in hospital, was short (mean 40.5 SD±32.1 minutes); and sleep efficiency, the ratio of the time spent asleep to the total recording period, was less than expected for this age group (mean 73.5 SD±22.9%). Both these parameters are stigmata of moderate depression. Rapid-eye-movement (REM) sleep was completely suppressed on the 2 nights CMI was infused and then returned to the pre-infusion baseline over the ensuing 8 nights (Figure 3).

There was no significant change in sleep efficiency with the two CMI infusions ($p > .2$, $< .3$, paired *t*-test). This suggests that the considerable improvement which all patients reported in their sleep, after the CMI infusions, was due to a fundamental change in the quality of their sleep, rather than merely due to sedation. Delta sleep, subsequent to the CMI infusions, was not significantly altered.

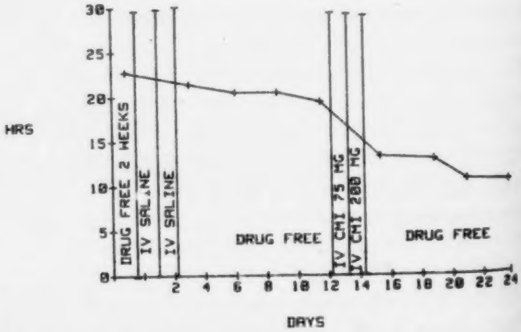

FIGURE 2. Mean Hamilton rating scale for 4 patients treated initially with IV saline.

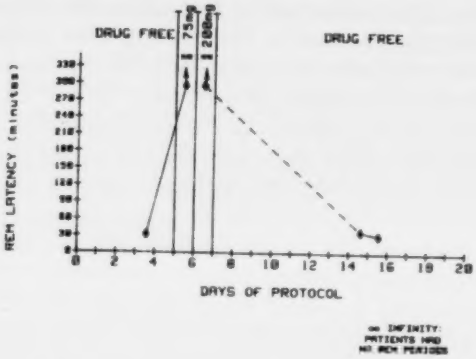

FIGURE 3. REM latency before and after treatment with IV clomipramine pulse-loading.

The saline infusions did not induce any significant changes in EEG sleep parameters.

Withdrawal pharmacokinetics performed after the second CMI infusion revealed a mean elimination half-life of 34 SD±3 hours, Concentration of zero time was 353 SD±127 ng/ml. Importantly, no significant amounts of desmethylclomipramine (>20 ng/ml) could be detected after the second infusion of CMI for at least 36 hours.

Discussion

Routine oral treatment with TCA's requires a minimum of 2 to 3 weeks at substantial doses to manifest optimal therapeutic effect (Hollister, 1983). It is well known that the extensive hepatic first-pass metabolism of orally administered TCAs prevents the rapid achievement of therapeutically effective blood levels (Evans et al., 1980). It is thus puzzling, as Klein et al. (1980) have noted, that there is such a paucity of studies on parenteral administration of these drugs. With respect to the i.v. administration of CMI, there have been several anecdotal reports and open studies attesting to its safety and superior efficacy in depression (Collins, 1970; Escobar et al., 1976; O'Flanagan, 1973; Symes, 1973), refractory depression (Dudley, 1980), and obsessive-compulsive disorder (Warneke, 1984).

There have been two double-blind controlled studies published in the English literature, comparing oral and i.v. routes of administration (Escobar, 1973; Faravelli, 1983). Both of these studies failed to show a significant difference in percent reduction in Hamilton ratings between i.v. and oral treatment groups. There is some cause, however, for caution in interpreting both of these studies. In the case of Escobar's 1973 study, there was considerable heterogeneity of diagnoses, e.g., only 43% of the i.v. group were diagnosed as suffering from endogenous depression versus 76% of the oral group. In spite of this, the authors concluded that there was a mean onset of action of 4 days for the i.v. group and 5 days for the oral. The same researchers in a subsequent paper (Escobar et al., 1976) commented on the importance of diagnostic criteria, and concluded "The results of this open trial, where specific diagnostic criteria were used, suggest i.v. administration of CMI to be a safe and feasible procedure, providing rapid therapeutic effects almost exclusively on unipolar and bipolar depressions, and a poor response in secondary affective disorders."

With regard to the more recent Faravelli paper, patients were begun at .5 mg/kg CMI, in a single a.m. dose, and raised to a maximum dose of 2 mg/kg after 10 days. At the end of 4 weeks, 30% of the patients had not achieved steady-state; combined plasma levels for CMI and its desmethyl metabolite were the same for both i.v. and oral groups and, thus, it is perhaps not entirely surprising that therapeutic response was equivalent. The authors suggest that a minimum, mean combined plasma level of 175 ng/ml is necessary for therapeutic improvement. Since it took 3 weeks to achieve these minimum levels in both groups of their patients, the important question still remained: If therapeutic levels are reached earlier, do patients improve earlier? Our data would appear to answer this question in the affirmative.

The evidence for impaired indoleaminergic functioning in subtypes of depressed patients, while not conclusive, remains as a highly viable hypothesis (Van Praag, 1984a). CMI, of all the TCAs, has consistently been shown to be the most potent inhibitor of the serotonin carrier pump in vitro (Tuck & Punell, 1973) and in vivo (Åsberg et al., 1977). Clinically, however, the significance of this has been obscured by the fact that the major metabolite of CMI, desmethylclomipramine (DCMI), is usually present in much greater concentrations (DCMI/CMI = 2.0–5.0) than CMI after oral administration and is a potent inhibitor of noradrenaline uptake (Mulgirigama et al., 1977). It has been suggested that increasing the serotonicity of orally administered CMI through the addition of 5-HTP and a peripheral decarboxylase inhibitor may shorten the latent period before a therapeutic response is observed (Van Praag, 1984b). Pulse-loading with i.v. CMI creates a system of moderate serotonicity, through the virtual absence of DCMI, and with extensive bioavailability to the central nervous system. It is also of interest to compare the results achieved by giving oral CMI at a dose of 225 mg/day (Van Praag, 1984b) as opposed to a total i.v. dose of 275 mg (Figure 4). Although there are obvious limitations to such a comparison, the effect nonetheless is striking and impels us to further investigation.

The magnitude of suppression of REM sleep by antidepressants may be predictive of clinical response (Kupfer et al., 1981b). Consistent with earlier preliminary work (Lacey et al., 1977), we found a profound suppression of REM sleep with parenteral CMI. The return of REM parameters to their pre-infusion state during the drug-free interval may herald an impending worsening of the patient's clinical status, which was aborted by initiating maintenance treatment. Alternatively, as has been suggested in sleep deprivation studies (Vogel et al., 1980), the buildup of REM pressure, i.e.. rebound itself, may be associated with clinical improvement. Of considerable interest is the finding that patients who respond to sleep deprivation have a greater likelihood of response to CMI infusions (Wirz-Justice, 1976). It is possible that this procedure may delineate a group of patients requiring serotonergic agents (Fahndrich, 1983).

Eight of the 10 patients in our pilot study began to evidence clinical improvement after achieving transient supra-therapeutic plasma levels of clomipramine, while their plasma levels were, in fact, declining. This paradox may be a manifestation of the activation of a time-dependent cellular process, as has been suggested for similar findings in animals (Chiodo & Antelman, 1980). Alternatively, it may represent a well-articulated pharmacodynamic process, anticlockwise hysteresis (Holford & Sheiner, 1981). This process occurs when there is an equilibration delay between systems (blood) concentrations and the effects (receptor) sites. The pattern of response observed in our patients seems to mirror that seen after the achievement of steady-state levels in patients treated with imipramine (Perel, 1983). This leads to the tentative conclusion that pharmacokinetic processes occuring in TCA therapy are mostly, but not entirely, the major determinants controlling the response lag time. Definition of the role of each factor awaits findings from a large-scale study currently underway.

Pharmacology of Combined Antidepressant/H_2-Blocking Drug Therapy

Stephen H. Curry, Ph.D.,[1] C. Lindsay DeVane, Pharm.D.,[1] and M. Michael Wolfe, M.D.[1]

Introduction

It has been observed that before the advent of antagonists of histamine-induced gastric acid secretion (H_2 blocking drugs), the treatment of ulcers with centrally acting drugs was common: nowadays, with H_2 blocking drugs available there is a tendency to treat psychiatric conditions with cimetidine. While this statement is clearly too broad to be universally true, it reflects increasing interest in two-pronged attack on human disease, and the combination of tricyclic antidepressants, and H_2 blocking drugs is an important component of this approach (Abernathy et al., 1984a; Somogyi & Gugler, 1979).

Little is currently known about the effects of individual tricyclic antidepressants and H_2 blocking drugs on each other. This is in spite of the well established fact that cimetidine inhibits hepatic microsomal enzymes and reduces hepatic blood flow (Puuronen & Pelkonen, 1979). Cimetidine is known to affect a wide variety of other drugs, including oral anticoagulants (Hetzel et al., 1979; Silver & Bell, 1979; Wallin et al., 1979; Willoughby, 1979), antipyrine (Roberts et al., 1981), phenytoin (Hetzel et al., 1981), ethanol (Feely & Wood, 1981), diazepam (Klotz & Reimann, 1980), chlordiazepoxide (Desmond et al., 1980), caffeine (May et al., 1982), theophylline (Campbell et al., 1981; Reitberg et al., 1981; Roberts et al., 1981), propranolol (Feely et al., 1981; Reimann et al., 1981), and lidocaine (Feely et al., 1982). In contrast, ranitidine appears less likely to affect other drugs (Abernathy et al., 1984a).

In one study with two oral antidepressants, administered separately, cimetidine decreased maximum plasma levels of imipramine, which is primarily metabolized by demethylation, but had no effect on plasma concentrations of nortriptyline, which is primarily metabolized by hydroxylation (Henauer & Hollister, 1984). With imipramine, the area under the curve of plasma levels against time was increased by cimetidine, implying inhibited metabolism. In another study, with imipramine only, after intravenous doses the elimination half-life of imipramine was increased, with no change in volume of distribution (Abernathy et al., 1984b). There was also no change in protein binding. After oral doses, the peak concentration, the area under the curve, and the half-life were all increased by cimetidine.

Methods

A recent study conducted at the University of Florida involved pretreatment with cimetidine or placebo for 2 days, amitriptyline test doses of 25 and 50 mg, blood samples for assay of amitriptyline and nortriptyline, measurement of blood pressure and pulse rate, and application of a digit symbol substitution test and a battery of visual analogue scales. Plasma concentrations were evaluated for time of maximum recorded concentration (T_{max}), maximum recorded concentration (Cp_{max}), half-life from 8 to 48 hours past amitriptyline dosage ($T_{1/2}$), and area under the curve (AUC). The AUC for amitriptyline included extrapolation to infinity using the formula $Cp_{(48)}/\beta$ where $Cp_{(48)}$ is the 48-hour concentration and β is the terminal phase rate constant for amitriptyline (AUC_{∞}). This was not done for nortriptyline, for which $AUC_{(0-48)}$ was calculated. Statistical analysis employed analysis of variance designed to identify differences between treatments, times, and subjects, and *t* tests for unrelated samples to determine significant differences between means. A level of $p<0.05$ was taken to indicate significance throughout. The methods and results of this work are presented in detail in two papers submitted for publication (Curry et al., in press; submitted, 1985).

Results

In a pilot experiment, it was shown that Cp_{max} and AUC were linearly related to amitriptyline dose for both amitriptyline and nortriptyline, with both measurements higher after higher doses. T_{max} and $T_{1/2}$ were similar for both 25 and 50 mg doses. Digit symbol substitution showed a dose-dependent depression in performance, with the greater depression after the 50 mg dose. Visual analogue scales recording sedation were similarly affected, but with no difference at the two dose levels.

In the interaction experiment, pretreatment with cimetidine apparently doubled Cp_{max} and AUC for amitriptyline, but halved these two measurements for nortriptyline. T_{max} and $T_{1/2}$ data were not affected. Mean concentration data are in the Table. Digit symbol substitution results correlated with plasma amitriptyline changes, and visual analogue scale data correlated with plasma nortriptyline changes. Blood pressure and pulse rate changes were consistent with plasma amitriptyline changes.

Discussion

At the commencement of this experiment, a cimetidine-induced slowing of amitriptyline metabolism was anticipated, and this was expected to affect plasma concentrations of amitriptyline and nortriptyline. The observations support this hypothesis. There was no reason to expect changes in volumes of distribution, protein binding, or rate of transfer of amitriptyline from the gastrointestinal tract to the general circulation. Furthermore, there was no reason to expect a detectable effect on nortriptyline kinetics. Since T_{max} and $T_{1/2}$ stayed unchanged, and Cp_{max} and AUC were much affected, we consider that this impairment is primarily of presystemic metabolism of amitriptyline (first-pass effect) such that the fraction of the dose reaching the general circulation as unmetabolized amitriptyline increased.

Since this study was conducted with single doses in healthy volunteers, caution must be exercised in extrapolation to long-term treatment in patients. However, it is reasonable to predict that this interaction will occur in patients, with doubled steady-state amitriptyline concentrations and halved steady-state nortriptyline concentrations predicted. This clearly has implications for patient management, especially in regard to plasma level monitoring, and a need for a clinical study of the importance of this interaction is indicated.

Acknowledgments: We are grateful to our subjects for their participation in this project, to the staff of the Clinical Research Center of the J. Hillis Miller Health Center of the University of Florida for their supervision of dosing and blood sampling, and to Mrs. Sandy Sundlof and Mr. Ron Miller for their skilled technical assistance in the drug assays.

Methylphenidate: Rate-Dependent Effects on Hyperactivity

Mark D. Rapport, Ph.D.,[1] and George J. DuPaul, Ph.D.[1]

Hyperactivity is currently viewed as an Attention Deficit Disorder (ADD) characterized by a short attention span, impulsivity, and excessive, nongoal directed activity which is pervasive over time and across settings (American Psychiatric Association, 1980). In recent years, there has been an increasing urgency in establishing effective treatment protocols for ADD children owing to the relatively high prevalence rate (i.e., 3% to 5% of school-age children) and protracted nature (Satterfield et al., 1982) of the disorder.

The most popular treatment for this disorder over the past decade (Rapport, 1983) involves the prescription of psychostimulant medication (e.g., methylphenidate, dextroamphetamine and, more recently, pemoline), which improves the performance of most ADD children on laboratory tests of sustained attention (Sykes et al., 1973), reflection-impulsivity (Brown & Sleator, 1979; Rapport et al., 1985a), and short-term memory (Rapport et al., 1985b; Sprague & Sleator, 1977), as well as their classroom on-task and academic completion rates (Rapport et al., 1980, 1982, 1985b). Despite the widespread use of psychostimulants with this population (Safer & Krager, 1983), there remains a dearth of information regarding the underlying mechanisms and/or specific overt variables which may contribute to their effectiveness.

Conversely, studies of central nervous system (CNS) stimulant effects in animal species have consistently shown that the drug effect often depends upon the rate of occurrence (the control rate) of a given behavior in a drug-free state, i.e., that the behavioral effect of the drug is rate-dependent (Dews, 1977; Dews & Wenger, 1977).

The results of laboratory investigations examining the existence of the rate-dependency phenomenon with human adults have been equivocal thus far (Dews & Morse, 1958; Stitzer & Domino, 1974). Recent investigations, however, have shown preliminary evidence of rate-dependent effects of methylphenidate and/or D-amphetamine upon the in-seat activity (Robbins & Sahakian, 1977) and operant key-pressing (Rapport et al., 1985) behaviors of ADD children. Unfortunately, examinations of rate-dependent effects of stimulant medication have been confined thus far to behaviors exhibited under contrived conditions and/or laboratory settings, thus limiting the applicability and external validity of the findings.

The present investigation sought to extend previous findings by examining the effects of several doses of methylphenidate upon a behavior which is integrally related to the measurement of an attention deficit (viz., the frequency of on-task behavior) in a setting which is especially problematic for most ADD children: The classroom. The purpose of the study was to determine the extent to which an overt behavioral variable (i.e., the rate of on-task behavior in the absence of medication) contributes to the medication effect upon the frequency of classroom on-task behavior or, stated differently, whether stimulant effects upon an exigent behavior in *esse situ* could be explained via a rate-dependency analysis.

Materials and Methods

Children with chronic problems of inattention, impulsivity, and overactivity were referred to the Children's Learning Clinic (CLC) of the University of Rhode Island by local pediatricians and school system personnel. A total of 20 (18 males and 2 females) children (weight range = 18.9 to 38.25 kg; median = 24.3 kg) between the ages of 6 and 11 years (mean = 8.1 years) participated in the study after obtaining informed consent from their parents and meeting each of the following criteria: a) an independent diagnosis by the child's pediatrician and CLC's directing clinical psychologist using DSM-III (American Psychiatric Association, 1980) criteria for Attention Deficit Disorder with Hyperactivity (ADD-H); b) a maternal report of a developmental history consistent with hyperactivity (Barkley, 1981); c) a maternal rating of at least two standard deviations above the mean for the child's age on the Werry-Weiss-Peters Activity Scale (Routh et al., 1981); d) a teacher rating on the Abbreviated Conners Teacher Rating Scale (ACTRS) above 15, the designated cutoff score for hyperactivity (Werry et al., 1975); e) performance on the Matching Familiar Figures (MFF) Test (Kagan et al., 1964) characteristic of a "fast-inaccurate or impulsive" responder, i.e., faster than average responses and higher than average error rates for the child's age; and f) free from any gross neurological, sensory, or motor impairment and not presently taking medication.

All children were of average or above average intelligence (mean IQ = 105; SD = 10.8) as assessed by the Peabody Picture Vocabulary Test-Revised, Form L (Dunn & Dunn, 1981), from families of low to middle socioeconomic status (Hollingshead, 1975), and "favorable responders" to methylphenidate according to recently defined criteria (Rapport et al., 1985a,b).

A double-blind, placebo-controlled, within-subject (crossover) design was used in which all children received each of the four doses following baseline measures. Order of drug administration was determined by randomly assigning each child to one of 24 possible counterbalanced drug orders. Methylphenidate was prescribed by each child's respective pediatrician in the following doses: placebo, 5 mg (range = .13 to .26 mg/kg), 10 mg (range = .26 to .53 mg/kg), and 15 mg (range = .39 to .79 mg/kg). Fixed doses (vs. mg/kg) were prescribed to reflect normal pediatric practice in the United States (Physician's Desk Reference, 1985) and because optimal dose has been shown not to depend on a child's body weight (Kinsbourne & Swanson, 1979; Rapport et al., 1985a,b). The methylphenidate was packaged in colored gelatin capsules by the pharmacist to avoid detection of dose and taste. Capsules were placed in individually dated envelopes to insure accurate dose administration.

Children were seen weekly at the CLC for individual testing using a battery of cognitive, learning, impulsivity, attention, and motor tasks during an intensive 8-week study period, which is detailed elsewhere (Rapport et al., 1985a,b). Only the classroom measures will be described herein.

The classroom phase of the experiment involved 5 consecutive weeks of observation. Following baseline data collection (1st week), parents were given a week's worth of medication in pre-dated envelopes at one dose level (i.e., placebo, 5, 10, or 15 mg methylphenidate). This procedure continued until a child received each dose for 7 consecutive days. All weekly dosage changes (e.g., switching from 15 mg to 5 mg) occurred on Saturdays to control for potential rebound effects. Parents were instructed to give their children a medication capsule each morning, 1/2 hr prior to breakfast, and to tell them it was a vitamin supplement (i.e., to help control for expectancy (Rapport et al., 1982). Both used and unused envelopes were returned to control for medication compliance.

Children were observed in their regular classrooms for 20 min intervals, 3 days per week across the 5-week evaluation period. Classroom observations began 1 1/2 to 2 hrs after the children's morning medication in an effort to improve upon previous dose response studies (Sprague & Sleator, 1977) by controlling for time after medication. Children completed in-seat academic work assigned by the teacher during this time and were unobtrusively observed by trained undergraduate and graduate students for 60 continuous intervals during each observation period throughout the study. Each interval was divided into 15 sec of observation followed by 5 sec for recording. Classroom teachers and observers were blind to both when medication was administered and specific doses.

A child's behavior was categorized as either on-task or off-task in a manner identical to that used in earlier studies (Rapport et al., 1980, 1982, 1985b). A response was defined as a discrete 15-sec interval in which a child was observed to be on-task. Response rate was obtained for each child by calculating the mean number of responses per 20 min interval (maximum daily response rate = 60 per 20 min) over the 3-day observation period within each experimental condition. Interobserver reliability checks of child behavior were taken on 33% of the observation days for all children, and at least once during each experimental phase. Obtained reliability estimates (Hopkins & Hermann, 1977) were computed for occurrence (mean = .95), nonoccurrence (mean = .88), and overall agreement (mean = .95) (Bijou et al., 1968), with a mean Kappa value of .83 obtained for all observations.

Results

The mean on-task response rates (responses per 20 min) and standard deviations for baseline, placebo, and the three methylphenidate (5, 10, 15 mg) conditions are presented in the Table. A one-way analysis of variance with repeated measures across the five conditions was significant ($F = 24.92$; d.f. = 4,76; $p < .001$), with a follow-up Newman-Keuls test revealing significantly greater mean on-task response rates in all three methylphenidate conditions compared to baseline and placebo ($p < .01$). The mean on-task response rate in the 15 mg condition was significantly greater than those in 5 ($p < .01$) and 10 ($p < .05$) mg. No further significant differences were found.

TABLE

Mean On-Task Response Rates (Responses per 20 min) and Associated Standard Deviations (SD) for Baseline, Placebo, and Three Active Methylphenidate Conditions (5, 10, 15 mg) in a Sample ($N = 20$) of ADD Children

Condition	On-Task Response Rate	
	Mean	SD
Baseline	32.37	12.32
Placebo	32.40	15.68
5 mg	41.90	11.21
10 mg	46.18	11.26
15 mg	51.96	4.63

Note: The maximum daily on-task response rate = 60.00.

Rate-dependent effects of psychostimulants upon behavior have been classically analyzed by examining the relationship between the control response rate (response rate under placebo) and the output ratio (the ratio of response rate after medication to control response rate) (Dews & Wenger, 1977). In keeping with tradition, Figure 1 was drawn with log control rate plotted on the abscissa and log output ratio (drug rate/control rate × 100) on the ordinate with regression lines for each dose fitted by the method of least squares. Correlations between the two variables were −.96, −.98, and −.99 for 5, 10, and 15 mg, respectively, with all three significantly different from zero ($p < .001$). Thus, a negative linear relationship was found between control rate and output ratio at all three doses. A test for equality of slopes, with control rate as the covariate and each dose treated as a separate group, revealed that the 15 mg slope was significantly steeper than both the 5 and 10 mg slopes ($F = 11.28$; d.f. = 2,54; $p < .001$).

A final analysis was performed owing to the controversy regarding whether fixed-dose or milligram per kilogram (mg/kg) plots

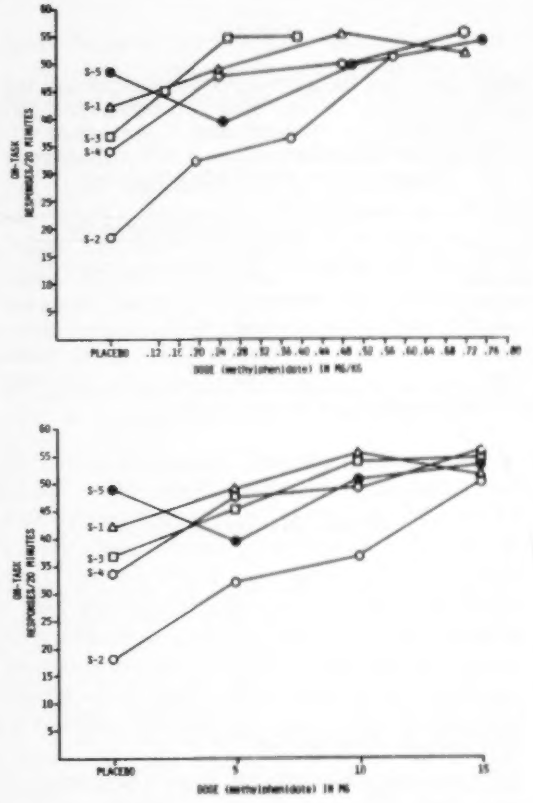

FIGURE 1. Log output ratio (drug rate/placebo control rate × 100) as a function of log placebo control rate for on-task response rate (responses per 20 min). Regression lines were fitted by the method of least squares for each dose. Individual scores across doses are represented by closed circles (5 mg), triangles (10 mg), and squares (15 mg).

should be used in evaluating dose effects in children receiving methylphenidate (Rapport et al., 1985a,b). Consequently, the on-task response rates of five children randomly selected from the participant group ($N = 20$) were plotted using both fixed-dose and mg/kg plots (*see* Figure 2). This procedure was used to facilitate graphical illustration and interpretation (i.e., drawn curves using all 20 children were too difficult to visually follow). A test of equality of the regression lines showed no signficant differences between the slopes of the dose-response curves obtained from the random subsample and the remaining 15 children, indicating that the former were representative of the total sample.

In examining the curves shown in Figure 2, it appears that children's on-task response rates show similar dose-related changes using both fixed-dose and mg/kg dose-response plots. Four of the five children (S-2, S-3, S-4, & S-5) performed optimally at the highest dose (compared with lower doses) regardless of whether fixed-dose or mg/kg plots were used; thus, corroborating the results of previous investigations showing individual responsivity to psychostimulant medication (Rapport et al., 1985a,b). Furthermore, weight calculated on a mg/kg basis does not appear to account for the obtained individual differences (e.g., note the differences in on-task behavior between S-2 and S-3 at .38 mg/kg).

Discussion

Our data have implications for both pediatric psychopharmacological research and the clinical practice of monitoring psychostimulants in ADD children. A review of the psychopharmacological research on ADD indicates that there have been no prospective empirical investigations which systematically assess whether a child's drug-free rate of behavior contributes to drug responsiveness (Reatig, 1984). The data presented herein establish this relationship by showing drug-induced proportional changes in ADD chil-

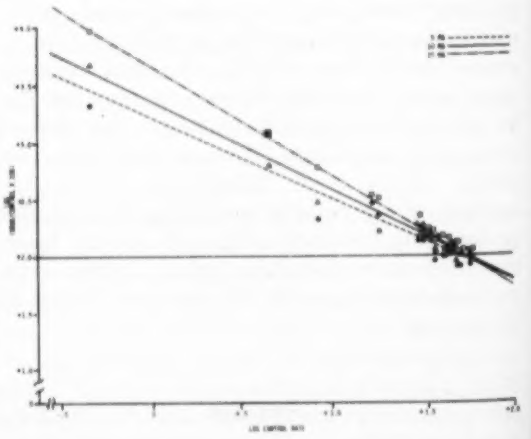

FIGURE 2. The mean on-task response rate per 20 min interval for five hyperactive children randomly chosen from the total group ($N = 20$) on placebo and three doses of methylphenidate. The top panel depicts dose-response curves in mg/kg. The lower panel shows dose-response curves in mg for comparison.

dren's attention which are consistent with the rate-dependency phenomenon found with lower species (Dews, 1977; Dews & Wenger, 1977). Thus, the rate of a child's overt behavior in a drug-free state clearly contributes to the effect of CNS stimulant on that behavior. The strength and shape of this relationship are affected by dose and the child's unique reaction to the drug, yet appear unrelated to body weight. Dosage should be directly manipulated in pediatric psychopharmacological studies and the cumbersome practice of using mg/kg dosage schedules may no longer be necessary (Rapport et al., 1985a).

The CNS stimulant methylphenidate is the most widely studied and prescribed medication for ADD children in the United States (Safer & Krager, 1983). Physicians typically use the titration method (Physician's Desk Reference, 1985) of increasing dosage until favorable reports are obtained by the parents and/or teacher. Both of these sources tend to base their judgments on the child's social behavior, which generally necessitates higher dosages for improvement than does cognitive performance (Sprague & Sleator, 1977). In order to assess the effects of methylphenidate on classroom performance, our data indicate that physicians need to obtain information regarding the child's rate of academic behavior both before and during clinical drug trials. School-based paraprofessionals may need to be recruited to provide this information to the pediatrician. The contribution of other variables (e.g., an individual's past history) and/or specific behaviors (academic completion and accuracy rates) to CNS stimulant effects in ADD children will need to be explicated in future studies.

The Therapeutic Effect of Clonidine in Attention Deficit Disorder With Hyperactivity: A Comparison With Placebo and Methylphenidate

Robert D. Hunt, M.D.,[1] Ruud B. Minderaa, M.D.,[2] and Donald J. Cohen, M.D.[1]

Introduction

Attention Deficit Disorder with Hyperactivity (ADD-H) has been estimated to affect approximately 250,000 children in the U.S.A. It is characterized by impulsivity, inattention, and hyperactivity (Hunt et al., 1982: Safer & Allen, 1976) which impairs academic learning, disrupts social and peer relations, and can greatly disturb functioning within the home and at school (Cantwell, 1975a: Halperin & Gittelman, 1982: Levy & Hobbes, 1981: Silver, 1981: Weiss & Hechtman, 1979). Recent evidence has established the persistence of this disorder into adolescence (Lerer & Lerer, 1977; Mendelson et al., 1971) and adulthood (Amado & Lustman, 1982: Weiss et al., 1979: Wood et al., 1976). ADD-H children may have an increased risk of developing anti-social behavior (Satterfield et al., 1982) and alcoholism and substance abuse (Eyre et al., 1982).

A genetic component to this disorder has been described (Cantwell, 1975b; Deutsch et al., 1982; Mendelson et al., 1971), which may suggest that it has a biological substrate. Altered noradrenergic functioning has been suggested by the low levels of urinary 3-methoxy 4-hydroxyphenylglycol (MHPG) (Shekim et al., 1979, 1982), and in increased human growth hormone (hGH) response to a clonidine challenge (Hunt et al., 1984).

Need for Alternative to Stimulant Medication

In spite of the excellent response of many children with ADD-H to stimulant medications such as methylphenidate and D-amphetamine, a substantial percent do not respond to or develop significant side effects from stimulants. Approximately 40% of well-diagnosed children have no response or exhibit a decrement in response on paired associate learning tasks following an acute dose of methyphenidate or cylert (Swanson & Kinsbourne, 1976). Their cognitive and social behavior may become exceedingly constricted and rigid. Although stimulant medication improves performance on selected cognitive laboratory tasks, the medication alone does not improve academic grades nor substantially alter other outcome measures (Gittelman-Klein, 1976, Quinn & Rapoport, 1974). Coupled with psychotherapy and special education, stimulants may improve academic adjustment and performance (Satterfield et al., 1979).

However, stimulant medications have multiple side effects and some specific contraindications for use. Transient side effects include anorexia, insomnia, stomach aches, afternoon withdrawal, and explosiveness (Cantwell, 1975a). Long-term side effects of stimulants may include growth suppression (Greenhill et al., 1980; Millichap, 1978), development of tics (Lowe et al., 1982), and hallucinosis (Young, 1981). Compliance with methylphenidate treatment is frequently low (Firestone, 1982; Sleator et al., 1982). There is a need for an alternative medication that would have the following characteristics: 1) fewer side effects and a more consistent duration of action; 2) therapeutic benefit for children whose ADD-H is associated with explosiveness, motor tics, personality rigidity; 3) safety in ADD-H adolescents who are at risk for substance abuse; 4) improvement in patient acceptance and compliance; and 5) more effective enhancement of academic performance.

Clonidine

Clonidine is an alpha-adrenergic stimulating agent which acts preferentially on presynaptic alpha-2 neurons to inhibit noradrenergic activity (Aghajanian & Bunney, 1977; Cedarbaum & Aghajanian, 1977; Titeler & Seeman, 1980). It stimulates release of hGH (Gold et al., 1979; Hunt, 1984), and inhibits norepinephrine (NE) release which decreases the level of the NE metabolite MHPG in the urine (Charney, 1982; Hunt, in press). Clonidine is useful as an antihypertensive agent (Manheim et al., 1982), an inhibitor of opiate withdrawal (Gold et al., 1980), and it may have some short-term antianxiety effects (Redmond, 1979).

Many patients with Tourette's Syndrome (TS) frequently share with ADD-H children problems of impulsivity, inattention, and motor restlessness (Cohen et al., 1980). Children with TS demonstrate decreased tics and improved calmness and attention on clonidine (Cohen et al., 1980; Leckman et al., 1983).

Following good results with an open pilot study of 7 ADD-H boys treated with clonidine (4 ng/kg/day), we performed a double-blind placebo-crossover in 10 children.

Method

Subjects

Ten children, ages 11.6±0.54 (mean±SE) years, participated in 12 weeks of active treatment with clonidine.

All of the children had received special education; half were predominantly treated in this fashion. Four of the children had one or more first-degree relatives with a distinct history of ADD-H or learning disabilities. The families in this study were in the 3.2±0.4 socioeconomic status (Hollingshead, 1965).

Seven (70%) of those completing the study had previously been treated with stimulant medication for 3.2±.7 (mean±SE) years at a dose of 0.35±.12 mg/kg. Three of the parents reported that the stimulant medication had been beneficial; four had discontinued stimulants because of significant side effects.

Subject Selection

To be eligible for the study, a child had to meet DSM-III criteria for ADD-H and score at least 2.0 standard deviations (s.d.) above normal on the Hyperactivity Index (Barkley, 1981) of the Connors Behavior Rating Scale (C-BRS) as rated by either parent or teacher (Conners, 1969). All subjects had an IQ greater than 80 and had no symptom of psychosis or primary mood disturbance. All were medically healthy with no cardiac, endocrine, or neurological disorder.

An additional baseline assessment included two weekly ratings on the Parents' and Teachers' version of the Parents' Child Behavior Checklist (Achenbach, 1978), a standardized psychiatric interview using the Diagnostic Inventory for Children and Adolescents (DICA) by Herjanic and Weiner (1981), and a developmental and personal history (Personal Data Inventory developed by Shaywitz, 1982). Academic and behavioral records describing academic performance, behavior, and psychological and educational testing were obtained from their schools. Physical and neuromaturational exams, a complete blood count, thyroid indices, lead levels, ceruloplasm, electrolytes, blood urea nitrogen, and an electrocardiograph were also performed. The children were either drug-naive or were drug-free for 1 month prior to beginning clonidine. Informed consent from parents and assent from the children was obtained after they received a detailed description of the study.

Double-Blind Treatment Design and Implementation

Since the effects of clonidine require several weeks to stabilize, active clonidine was administered for 8 consecutive weeks. After 2 weeks of baseline assessment, subjects were randomly assigned to begin with either active clonidine or placebo for 2 weeks. The group initially treated with placebo ended their treatment with 2 additional weeks of placebo; the group initially treated with clonidine ended with 4 weeks of placebo. Subjects were randomly assigned to a treatment group by a research assistant, leaving clinicians blind to the treatment sequence. Parents were given coded tablets with computer-generated instructions specifying the tablet to be taken for each dose. Parents, teachers, children, and one clinician rater remained blind to the study design.

Medication Dose and Rate of Increase

The dose of clonidine was increased by 0.05 mg every other day until a dose of 4-5 µg/kg/d (about 0.05 four times a day) was achieved. Clonidine was tapered off gradually when children were returned to placebo in order to avoid a hypertensive reaction. Blood pressure and pulse were measured monthly at each clinic visit.

Evaluation of Therapeutic Response

Every 2 weeks parents and teachers completed the revised Conners Parents' Behavior Rating (48-item) and the Teachers' Behavior Rating (28-item) scales, respectively. *Every month* parents and children had a videotaped interview and repeated behavioral ratings. Two clinicians blind to the treatment condition rated the children using a scale which quantitatively scores the DSM-III specified symptoms for ADD-H; all raters also completed a global rating of improvement. A brief neuromaturational assessment battery was repeated monthly to monitor visual-motor coordination as evidenced by: sequential finger tap, the peghole test, the marble sorting, printing, and the Coding and Digit Symbol tasks from the Wechsler Intelligence Scale for Children—Revised (WISC-R). Auditory attention was assessed using Digit Span (forward and backwards). The Kagan Matching Familiar Figures Test provided an index of impulsivity, visual scanning, and frustration tolerance.

Data Analysis

Behavior and neuromaturational rating scores were compared at baseline, 1 month, 2 months, and during placebo withdrawal using a one-way analysis of variance with repeated measures. Comparisons between baseline and final week of clonidine (2 months) and clonidine and placebo were analyzed using a two-tailed t test.

Results

Clonidine's Effect On Conners' Behavior Ratings (*See* Table 1, Figures 1 and 2.)

Composite Ratings: Eight of the 10 children were rated as at least mildly (10 to 24%) improved by one observer. Seven children were rated as at least moderately (25 to 49%) improved by two observers; this rating was considered the minimal criteria for definite improvement. Six showed a substantial (50 to 74%) improvement as rated by at least one observer; 5 were rated as at least 50% improved in the classroom. Four subjects were reported to be substantially improved in two settings.

Teachers' Ratings

Before treatment with clonidine, teachers' total behavior rating on the Conners' 28-item scale for the group was 49.00±5.20 (mean±SE). After 8 weeks of treatment with clonidine the bi-weekly average of the teachers' behavior ratings demonstrated progressive improvement, with a final rating of 25.79 ±1.31 ($p = 0.001$). Similarly, the teachers' "Hyperactivity Index" (Barkley, 1981) dropped from pretreatment level of 1.99±0.16 to 1.12±0.06 at the end of active clonidine treatment ($p = 0.001$). Significant changes in conduct ($p = 0.4$) and inattention

TABLE 1

Overall Improvement for Individual Subjects During Treatment

Subject No.	Rater		
	Parent	Teacher	Clinician
1	1	2	1
2	2	3	1
3	4	3	3
4	2	2	2
5	2	3	3
6	2	0	1
7	3	2	3
8	0	NA	—
9	2	2	2
10	2	NA	2

Key:
0 = no significant change (less than 25% improvement or deterioration)
1 = mild improvement (10 to 24%)
2 = moderate improvement (25 to 49%)
3 = substantial improvement (50 to 74%)
4 = extreme improvement (more than 75%)
— = 25% overall deterioration
NA = not ascertained

BASELINE - CLON 2 mo	0.003	0.001	0.01
CLON 2 mo - PLACEBO	0.02	0.05	0.04

FIGURE 1. Total scores. Behavioral response to clonidine and placebo (crossover).

($p = 0.5$) were also noticed by teachers. Five of the 8 children on whom ratings were completed demonstrated at least moderate (25%) improvement in overall behavior ratings; 5 were substantially (75%) improved. During the post-clonidine placebo period, the teachers observed at least a moderate (25 to 50%) deterioration in all but one child. Teachers' written comments indicated that children appeared "more relaxed," and had much more "on-task activity" during clonidine treatment and exerted more purposeful effort at school. They reported that children seemed less easily distracted or frustrated. Teachers described these children as being "better accepted by peers" and "less aggressive and explosive."

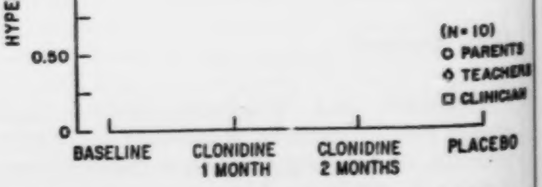
Parents' Ratings

Parents documented a similar response to clonidine treatment. Parents' overall behavior ratings (Conners' 48-item scale) for the group declined from a pretreatment level of 66.85±5.75 to 43.00±6.29 ($p = 0.003$) after 8 weeks of clonidine. Parents rated significant improvement in the following areas: "Hyperactivity Index" (2.03±0.16 to 1.34±0.21; $p = 0.004$); "Conduct Problems" (1.38±0.16 to 0.99±0.10; $p = 0.01$); and improvement in "Learning Problems" (2.36 ±0.17 to 1.53±0.28; $p = 0.007$); but no significant improvement occurred in factor scores for Anxiety or Psychosomatic problems.

During clonidine treatment, 3 children demonstrated a substantial decrease (50%), while 4 had a moderate (25%) decrease, in ADD-H symptoms. Three of the children, including both girls, showed no overall change according to their parents. Parents' ratings of children's overall behavior on subsequent *placebo* showed a substantial deterioration in 4 children, a moderate deterioration in an additional 2 children, and a mild deterioration in 2 more children; 1 child demonstrated slightly improved behavior. Ratings for "Hyperactivity" deteriorated to about the same degree during placebo.

Clinicians' Ratings

Based on direct clinical interviews and a review of the behavioral ratings, the clinicians reported a significant improvement in 8



p-VALUES	PARENTS	TEACHERS	CLINICIAN
BASELINE - CLON 2 mo	0.004	0.001	0.03
CLON 2 mo - PLACEBO	0.002	0.04	0.12

FIGURE 2. Hyperactivity index. Behavioral response to clonidine and placebo (crossover).

subjects in the primary DSM-III symptoms of ADD-H. Three children improved moderately and 5 improved mildly in overall symptoms of ADD-H.

On withdrawal from clonidine, clinicians also reported that 7 of 10 children developed more severe ADD-H symptoms, which were extreme in 4 subjects and moderate in 1. Ratings of "Hyperactivity" showed deterioration in 6 subjects; inattention and impulsivity worsened in 7 subjects on placebo. Clinicians' ratings of "Impulsivity" showed a similar response to placebo.

By direct clinicians' observation, these children were more cooperative during interviews while taking active clonidine. They performed the neuromaturational and cognitive tasks with less resistance and protest. Their mood appeared improved. They frequently described experiences of feeling more in control of anger and irritability, and having greater ability to solve problems. They expressed increased pride in their achievements and experienced less conflict and oppositionality at home and at school. They described an increase in their efforts to resolve conflicts and solve problems. They appeared more thoughtful, psychologically minded, and self-confident. This was most impressive in 3 children who otherwise had experienced minimal therapeutic benefit from their prior treatment with methylphenidate.

Placebo Withdrawal

When subjects returned to the placebo condition, their behavior rapidly deteriorated; symptoms usually returned within 2 to 4 days. Three of the children were unable to remain off medication for the full 4 weeks due to profound worsening of behavior that threatened to disturb classroom performance and placement. A significant deterioration in overall behavior for the group was noted by teachers ($p = 0.05$), parents ($p = 0.02$), and clinicians ($p = 0.04$).

Neuromaturational Testing

The scores for the neuromaturational tests showed that clonidine tended to improve performance in some tests beyond the effect of practice, but none of these changes reached significance. Clonidine's main effect on neuromaturational tasks was to diminish variability. This may indicate reduced distractibility and off-task behavior on clonidine. Clonidine did not impair subjects' performance of psychomotor tasks.

Side Effects

The main side effect was *sleepiness*, which occurred primarily for 30 to 60 minutes beginning about 1 hour after clonidine administration. In all but one child, this sleepiness subsided after 3 weeks and was dose dependent. For this child, sleepiness limited clonidine's usefulness. The mean *blood pressure* decreased 10% on clonidine; this produced no subjective symptoms other than occasional light-headedness immediately after standing or strenuous exertion. One child who had symptoms of mild *depression* prior to clonidine became more tearful and unhappy on clonidine. Children without prior symptoms of depressive disorder did not become depressed on clonidine.

Discussion

Clonidine significantly improved the overall behavior ratings of "Hyperactivity," "Impulsivity," and "Inattention" in children with ADD. Two children improved moderately (10 to 25%) on clonidine, while 5 improved substantially (25 to 50%). One subject showed no change or a slight deterioration on clonidine. The two girls were among the three poorest responders.

Clinical Impressions

Clonidine seemed to facilitate a maturational development characterized by increased reflectivity, heightened purposeful, goal-directed behavior, and less oppositional behavior. Clonidine enhanced children's frustration tolerance and enabled them to sustain effort toward age-appropriate objectives without feeling overwhelmed, inadequate, or incompetent.

Clinical Differentiation of Good and Poor Responders to Clonidine

The ADD-H children who responded best were those who had been overactive and lacked inhibition. Their capacity for social-relatedness and purposeful activity appeared intact but had been under-utilized due to their impulsivity. One child who did not benefit from clonidine met DSM-III criteria for both ADD-H and schizoid personality disorder. While this child was calmer on clonidine, he also became more disorganized, passive, and undirected. The poor response of two ADD-H girls may suggest a slightly different clinical or neurochemical process in these individuals.

Noradrenergic Mechanisms in ADD-H

The finding of therapeutic benefit from clonidine in ADD-H is of heuristic as well as practical significance, since it may advance our understanding of the role of noradrenergic mechanisms in this disorder.

Clonidine not only directly inhibits noradrenergic excitation, as evidenced by decreased firing of the locus coeruleus (Aghajanian & Bunney, 1977; Starke & Altman, 1973), and by diminished MHPG production (Cedarbaum & Aghajanian, 1976, 1977; Hunt et al., 1984; Leckman et al., 1980). Clonidine also has a modulating effect on the firing of dopaminergic neurons under conditions of stress (Antelman & Caggiula, 1977). Clonidine's effect in children with ADD-H may reflect both direct noradrenergic effects on cognition and anxiety—leading to improved frustration tolerance and performance—and secondary modulating effects on other monoamine systems. Chronic administration of a noradrenergic agent such as clonidine may alter the sensitivity of non-adrenergic receptors, such as dopamine, to their neurotransmitters (Cooper et al., 1978).

Norepinephrine (NE) mediates the expression of anxiety which may occur during phobic or panic states or during opiate withdrawal. NE activity of the locus coeruleus as measured by implanted electrodes in unanesthetized cats increased during arousal from sleep to wakening and in response to the introduction of a novel stimulus (Aston-Jones & Bloom, 1981; Foote & Bloom, 1979). This NE activation increased arousal and external vigilance of the animal. The symptoms of ADD-H may suggest a state of increased arousal that causes stimuli to seem excessively novel and engaging.

Biochemical factors may distinguish these children from normal, and may eventually contribute to predicting medication response. Clonidine may be preferentially useful in a biologically definable subgroup of noradrenergically over-responsive ADD-H children, who may be identified by levels of urinary MHPG or by response to a clonidine or yohimbine challenge.

Clonidine may be preferable to methylphenidate in children who have chronic tics, decreased appetite (anorexia), sleep disturbance (insomnia), excessive afternoon withdrawal, or growth retardation. It may also be beneficial to ADD-H children who are primarily impulsive, unreflective, and easily emotionally overwhelmed.

Further subtyping of ADD-H according to diagnosis of conduct disorder (Satterfield et al., 1982), aggression (Milich et al., 1982), degree of motor activity (Porrino et al., 1983), the presence of specific learning disabilities (Andrulonis et al., 1982; August and Stewart, 1982; Kupietz et al., 1982; O'Brien, 1982), and the extent of affective lability, explosiveness, or depression may clarify clinical or biological differences in ADD-H children.

We are performing an open-ended comparison of methylphenidate and clonidine on an additional 20 ADD-H children using similar behavioral and neuromaturational measures. Our clinical impressions support our earlier observations that clonidine treatment improves compliance, task orientation, and frustration tolerance, and reduces oppositional behavior. Parents especially appreciate the fact that clonidine can be given in the late afternoon or evening without interfering with the child's appetite or sleep. In some cases of extreme distractibility a combination of clonidine and low doses of methylphenidate appears safe and effective.

Further research is needed to compare clinical response of ADD-H children to clonidine and methylphenidate and to identify biochemical and clinical predictions of differential response.

The Use of MK-801, a Novel Sympathomimetic, in Adults With Attention Deficit Disorder, Residual Type

Fred W. Reimherr, M.D.,[1] David R. Wood, M.D.,[1] and Paul H. Wender, M.D.[1]

Introduction

Attention Deficit Disorder (ADD) is one of the most frequently treated psychiatric disorders of childhood. However, of the diverse treatment approaches available, only the stimulant medications, particularly methylphenidate and dextroamphetamine, are generally accepted as effective. Unfortunately, treatment with stimulants presents several very significant problems.

One of the most serious is the risk of abuse. This is particularly true with adolescent or adult patients and makes physicians reluctant to consider clinical trials of stimulants if ADD is suspected. In the younger patient with ADD, parents may use the medication intended for their children. As a result, many patients who might be strongly responsive to medication are not treated with stimulant medication.

A second problem is the partial or complete unresponsiveness to stimulants of a significant percentage of patients with ADD. Although unexplained, this variability in response may reflect "artificial" factors such as misdiagnosis, poor compliance, or social conditions. Conversely, a significant percentage of these patients may represent "true" pharmacologic failures.

Finally, even when they are effective, the stimulants have a number of undesirable features. The requirement that they be taken two to four times per day promotes noncompliance. Pemoline, an alternative longer acting stimulant, is associated with liver problems, is a difficult medication to start, and has questionable long-term efficacy. Many patients or their families are not comfortable with regular use of stimulant medication. In children there is the possibility that all three medications will lead to diminished growth.

In the past it was felt that ADD disappeared with the onset of adolescence and did not occur in adulthood. Recent evidence suggests that it may continue through adolescence and into adulthood. The American Psychiatric Association has officially recognized this possibility by including ADD, Residual Type (ADD,RT) in the DSM-III (Diagnostic and Statistical Manual—3rd ed., 1980). This development facilitates conducting clinical trials of experimental medications in ADD, since it allows one to avoid the special requirements attached to the use of experimental medications in children.

Collectively, these factors have led us to seek new pharmacologic approaches to the treatment of ADD. Preliminary work with a novel experimental compound developed by Merck Research Laboratories, MK-801, suggested that it merited testing in patients with ADD. Chemically, it is considered a dibenzocycloalkenimine, but it cannot be classified as a member of any accepted family of pharmacologic agents. In preliminary animal studies it is unique among chemical agents in possessing anticonvulsant, sympathomimetic, and anxiolytic actions. No other chemical is known to possess this cluster of properties.

In studies of radio-ligand binding, MK-801 does not compete with apomorphine, spiroperidol, serotonin, LSD, WB 4101 (measuring norepinephrine binding sites), quinuclidinyl benzilate (QNB) (measuring scopolamine binding sites), muscimol (measuring GABA binding sites), or 2-chloroadenosine. It does compete with diazepam binding acutely, but not chronically.

Central sympathomimetic activity has been assessed by measuring the induction of rota-

tion in rats with unilateral nigrostriatal lesions produced by 6-hydroxydopamine (Clineschmidt, 1982b). MK-801 produced ipsilateral rotation which is usually produced by indirect dopamine agonist agents such as amphetamine, amfonelic acid, or methylphenidate. This effect was reduced by pretreatment with haloperidol, clozapine, prazosin (an alpha adreno-receptor antagonist), and alpha-methyl-paratyrosine. It was blocked completely by reserpine.

MK-801 also produced an increase in locomotor activity similar to that observed in animals treated with amphetamine, amfonelic acid, and methylphenidate (Clineschmidt, 1982b). Reserpine blocked this effect when it was produced by MK-801, methylphenidate, and amfonelic acid, but only partially inhibited the increase in activity produced by amphetamine. Alpha-methyl-para-tyrosine markedly reduced the increase in locomotor activity seen with amphetamine, but did not change the effect occurring with MK-801, methylphenidate, and amfonelic acid. All were blocked by haloperidol. Prazosin only blocked MK-801 and amphetamine.

Its anxiolytic properties have been examined in two different studies with rats (Clineschmidt, 1982c). Animals were taught to obtain food by pressing a lever; this response was then punished with electroshock. The rate of lever pressing following food deprivation was measured after treatment with diazepam, MK-801, and placebo. Both MK-801 and diazepam produced an increase in the rate of lever pressing. In a second study, fluid-deprived rats were given electrical shocks when they took sips of water. The number of sips of fluid was measured in rats treated with placebo, MK-801, and chlordiazepoxide. Both active agents produced an increase in the number of sips of water that the rats took. In a similar experiment done with squirrel monkeys, MK-801 produced no anxiolytic effect.

MK-801 has shown significant anticonvulsant activity in mice, preventing seizures induced by bicuculline and with electroshock (Clineschmidt, 1982a). This effect occurred at a dose of MK-801 that was lower than any of the comparison medications [clonazepam, phenobarbital, diazepam, phenytoin, (Y)-acetylenic GABA (gamma-aminobutyrate), sodium valproate, or trimethadione]. MK-801 also blocked seizures induced in rats with electroshock, pentylenetrazol (Metrazol), strychnine, or bicuculline. In this second set of studies with rats, MK-801 showed a spectrum of activity similar to phenytoin and unlike clonazepam. The anticonvulsant action of MK-801 was not affected by anticholinergics, antihistamine H1 receptor blockers, cimetidine, or antiserotonin agents (cyproheptadine, cinanserin, methylsergide, or methergoline). The action was antagonized by naloxone, theophylline, and haloperidol (most strongly). Its anticonvulsant action was completely reversed by HEAT and phenoxybenzamine, alpha-adrenoceptor blockers. Its anticonvulsant action was potentiated by propranolol.

Several small, open trials have been conducted in human subjects. In patients with seizure disorders, MK-801 appears to have anticonvulsant activity. Additional studies are being conducted. In 14 patients with anxiety disorders, a majority reported that it aggravated their symptoms and produced feelings of agitation. In a small number of patients with retarded depressions, one patient developed a confusional state and the others showed only modest improvement before termination of treatment.

Methods

This study was an open 6-week, outpatient trial limited to 10 patients. Treatment for more than 6 weeks with MK-801 was not available under any conditions. This project was approved by the Institutional Review Board of the University of Utah Medical Center.

Potential patients had to meet the following inclusion criteria:

1. ADD in childhood as defined by DSM-III;
2. Presence of attention difficulties as an adult;
3. Presence of hyperactivity as an adult; or
4. Two of the following:
   a. Quick or excessive temper,
   b. Poor organization or difficulty completing tasks,
   c. Over-reactivity to stress,

d. Excessive mood lability with dysphoric episodes, or

e. Impulsivity.

5. Females were required to be infertile;

6. Ages 21 to 65;

7. Five days drug-free; or

8. History of positive response to stimulant medication.

Potential patients were rejected if they met any of the following exclusion criteria:

1. Recent use of neuroleptics;

2. Major medical or neurological disease;

3. Recent history consistent with alcoholism, antisocial personality disorder, or drug abuse;

4. Significant abnormality on entry electrocardiogram (ECG), complete blood count (CBC), urine analysis (UA), blood chemistry, or physical examination;

5. History of allergic reaction to multiple drugs; or

6. Current or past history of major mood disorder, schizophrenia, psychotic symptoms, borderline personality, schizotypal personality, organic brain syndrome, or mental retardation.

Patients meeting these criteria were given a copy of the informed consent agreement containing a detailed description of the study. This document had been approved by the Institutional Review Board of the University of Utah Medical Center. Patients were instructed to review this document carefully and an appointment was made in 4 to 7 days to begin the study.

Patients initially received 7 days of placebo and then continued in the study if they still met the criteria for inclusion. Visits were at 1, 2, 3, 4, and 6 weeks. The following psychiatric rating instruments and medical measures were used:

1. Physician's global ratings of improvement (CGI) was obtained at each visit. This scale is a 7-point scale ranging from very much improved to very much worse.

2. Physician's global ratings of severity (CGS) was obtained at each visit. This is a 7-point scale ranging from no sign of illness to extremely symptomatic.

3. The Attention Deficit Disorder Scale (TADDS), a weighted scale of hyperactive behavior, was obtained at each visit. This scale assigns the following points for each area of symptoms:

12 points for inattention,
8 points for overactivity,
8 points for temper,
4 points for emotional reactivity, and
4 points for mood instability.

4. The Global Assessment Scale (GAS) at 0 and 6 weeks.

5. Vital signs at each visit.

6. Physical examination at 0 and 6 weeks.

7. ECG, UA, blood chemistry, and CBC at 0, 1, 2, 4, and 6 weeks.

The starting dose of MK-801 was .025 mg three times a day (t.i.d.). Maximum dose was .150 mg t.i.d. A flexible dosing schedule was followed.

Results

Ten adults, 6 males and 4 females, with ADD,RT were treated with MK-801. The average age of the subjects was 33. No patients were dropped during the placebo washout period and 8 completed the entire 6 weeks. Two dropped out at the third week because of an inadequate response to the medication.

We used TADDS, the CGI, and the CGS to classify patients as either responders or nonresponders. On the CGI, patients had to be rated as moderately or markedly improved to be considered treatment responders. On TADDS they had to show a 50% or greater improvement. On the CGS, they had to be rated no more than mildly ill. (We were unable to use the GAS to categorize the response of our patients.)

All three measures (TADDS, the CGI, and the CGS) produced similar results. For instance, on the CGI patients fell into two groups. Five of 10 patients were consistent responders. They improved and maintained their improvement for the full duration of the study. Five of the 10 patients were transient responders. These patients (including 2 who dropped out after 3 weeks of treatment) responded for 1 to 3 weeks in the beginning of the study, but did not maintain their improvement. The other two measures (TADDS and the CGS) produced the same groups, but the numbers of patients in each group changed by plus or minus 1 patient.

Three characteristics of the pattern of response are noteworthy. First, although our sample sizes are quite small, women responded better to MK-801. Three out of the 4 women (75%) in the study were rated as consistent responders. Conversely, only 2 out of the 6 men in the study (33%) were consistent responders.

Second, our patients showed a response within 1 to 2 weeks. This is similar to the effect observed with other stimulant medications which produce their response with no latency. The percent of symptoms on TADDS remaining each week is presented in Figure 1. The total score has been corrected to give equal weighting to each of the five factors on TADDS (concentration, hyperactivity, temper, mood, and emotional over-reactivity) because the raw score gives relatively greater weighting to concentration. Zero represents complete remission of all symptoms measured by TADDS. Within a week of treatment most patients had obtained a steady state of improvement.

Third, there seemed to be differences in the relative amount of improvement occurring in each of the symptoms measured by TADDS. Mood was most strongly affected. Concentration was least improved while hyperactivity, temper, and emotional reactivity fell in between. This is illustrated in Figure 2 which shows the average improvement at weeks 2, 3, 4, and 6. A 68% improvement occurred in mood. Hyperactivity, temper, and emotional reactivity averaged a 57% improvement. Concentration showed only a 43% improvement.

Medication side effects were minor. Six subjects maintained the same weight while two lost and two gained weight. There were no changes on the ECG or in pulse rate. Mean diastolic blood pressure dropped from 80 to 76. Mean systolic blood pressure dropped from 121.5 to 115.4. All side effects were mild to moderate in intensity. Additional side effects included dizziness (reported on four occasions), headache (reported on two occasions), diarrhea (reported on two occasions), increased appetite (reported on two occasions), insomnia (reported on two occasions), jitteriness (reported on two occasions), and confusion, memory loss, difficulty with ejaculation, fatigue, tinnitus, heart burn, and itching (all reported once). At the final visit, 5 patients reported side effects and 5 reported none. One patient had his dosage reduced to a relatively low level due to side effects. In this patient the trial was terminated at the third week due both to the presence of these side effects and the lack of a therapeutic response to MK-801.

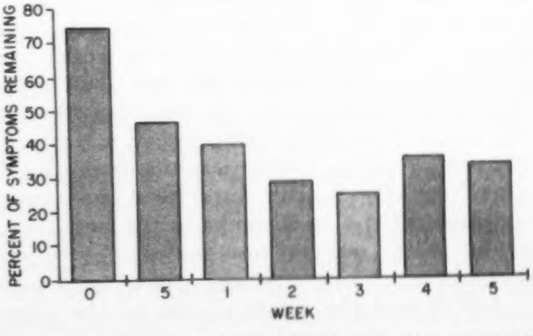

FIGURE 1. Percent of symptoms remaining at each visit as measured by the TADDS.

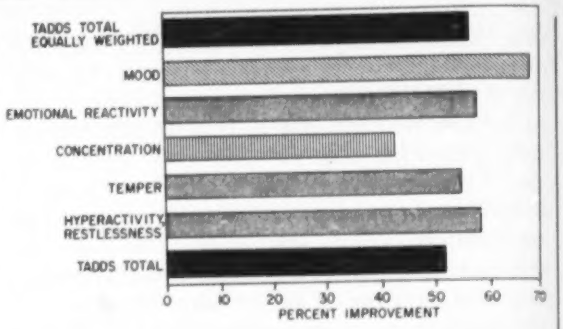

FIGURE 2. Percent improvement reported at weeks 2, 3, 4 and 6.

Although the dosing schedule was flexible, the majority of the patients were on .15 mg to .3 mg per day in three divided doses. Figure 3 contains a plot of the distribution of the total daily doses of MK-801 reported at weeks 2, 3, 4, and 6. The darker bars show the frequency of a particular dosage range in the patients classified as consistent responders with the CGI. The median dosage of the responders was .2 mg per day. The median dosage of the nonresponders was .225 mg per day. This plot shows that although most responders were in the .1 to .3 range, several responders were well above this range. A dosage plan that may be used in future studies will be discussed below.

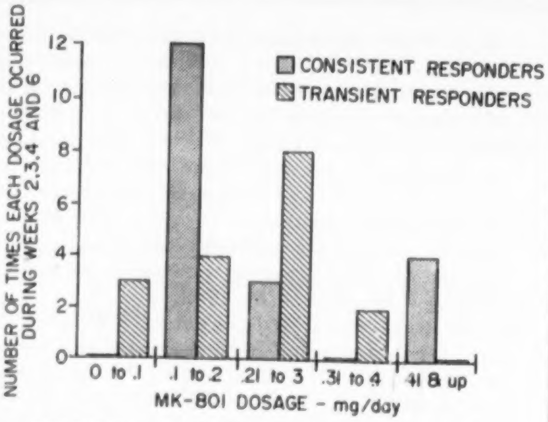

FIGURE 3. **Dosage distribution of MK-801.**

Conclusion

Several factors encourage optimism about the possible therapeutic value of MK-801, although the findings of this open, uncontrolled investigation must be interpreted with caution. First, there was no evidence that the patients abused or increased the dose of MK-801. Nor did they report any feelings of euphoria or increased energy.

Second, MK-801 appeared "different," not merely a less effective substitute for dextroamphetamine or methylphenidate. If one views ADD as having both a cognitive and an emotional component, MK-801 would appear to be more effective on the emotional component.

Third, several of our patients were outspoken in favor of MK-801. Even months later, several felt that they did better on MK-801: that with it they were more calm, in better control, and less reactive. As noted above, this was particularly true among our women patients. Two would not return to stimulants after being on MK-801.

Finally, in recent years we have conducted a number of open trials and controlled trials with small numbers of patients testing potential alternative medications for the treatment of ADD. These trials have focused on two classes of drugs: the monoamine oxidase inhibitors and metabolic precursors (Wender, 1983; Wood, 1985). This trial of MK-801 has been one of the most encouraging of these investigations.

The inclusion criteria that we adopted for this study present an important question concerning methodology in future drug studies of ADD. Should one select potential patients with ADD who are drug naive or should one select patients who have in the past been treated with stimulant medications? This question is more complex than it might appear initially. One would normally feel more confident about the diagnosis in a patient whom he had known for a significant period of time and had treated successfully in the past. Conversely, taking a patient off a medication which is producing a significant positive response is not easy. Research protocols usually require a drug-free interval of at least 1 week before starting the experimental treatment. However, it is difficult to know if this is an adequate period of time to allow a potential patient to recover from the lingering effects of past treatment with a psychoactive medication.

What dosage of MK-801 should be used in later studies? There appeared to be a bimodal dosage distribution among the consistent responders. One tenth of an mg per day in divided doses would be a reasonable starting dose. This should be raised very slowly to .25 mg per day over the next several weeks. If there has been no response after 3 weeks at this level, and if the patient can tolerate a higher dose, then a 1-week trial at a substantially higher dose such as .4 mg per day should be tried. This scheme would allow patients to be tried on both dosage levels which produced successful results in this study.

In light of a response rate of at least 50%, we feel additional studies with this agent in ADD,RT and normal childhood ADD are indicated. There might also be a role for this compound in other illnesses characterized by excessive temper, emotional reactivity, or impulsivity, such as borderline personality disorder or other personality disorders, particularly in women.

In summary, this was a short-term, open trial of MK-801. Half the patients were considered to be positive consistent responders to MK-801. The other half demonstrated a transient positive response to MK-801. Among the specific symptoms we monitored, mood showed the greatest relative improvement with MK-801. Temper, emotional reactivity, and over-activity all improved more than concentration. MK-801 appeared to be effective in the treatment of ADD,RT and its response appeared to be qualitatively different from that observed with the normal stimulant medications.

The Prevalence of Tardive Dyskinesia in a Mentally Retarded Population[1]

Mary Ann Richardson, Ph.D.,[2] Gary Haugland, M.A.,[2] Raymond Pass, Ph.D.,[2] and Thomas J. Craig, M.D., M.P.H.[3]

Introduction

Mentally retarded (MR) patients comprise a nonpsychiatric population that has routinely been exposed to long-term neuroleptic treatment as a behavioral control measure. Rates of neuroleptic use among MR patients have been substantial in the past (25 to 60%) and, though in recent years there has been a trend to reduce dosage or discontinue treatment, these agents are still commonly used in these patients (Davis et al., 1982; Lipman et al., 1978). Unfortunately, there is a scarcity of data concerning the true prevalence of tardive dyskinesia (TD) and risk factors for its development across the full range of the MR. One study reported a 20.4% rate of the disorder among institutionalized MR children (ages 11 to 16) (Paulson et al., 1975). In that investigation the presence or absence of TD was not studied in relation to other patient characteristics. Another report, of parallel studies in two locations ($N = 95$), reported a 33% prevalence of TD (Gualtieri et al., 1982). However, that study dealt with a patient population that was highly restricted since subjects were all referred by treating physicians who felt a trial neuroleptic withdrawal should be attempted, and further used inclusionary criteria such as an educational or workshop placement. A multiple regression analysis was performed on the data collected at one of the locations ($N = 38$). The patients at that location were characterized by a mean age of 19.4 years, a mean treatment duration of 8.3 years, a mean IQ of 31.2 and a mean chlorpromazine (CPZ) equivalent dose of 239.9 mg. The analysis used moderate to severe TD as a dependent measure and isolated three significant independent variables; total lifetime exposure to neuroleptics, IQ, and the age at which neuroleptic treatment began. A review of TD studies in the MR including the report just described, with a total subject pool of 122, found rates for TD prevalences ranging from 29 to 36% (Kalachnik, 1983). The present study sought to add to this literature by a large-scale investigation in an institutionalized MR population. The investigation was also undertaken to study the presence or absence of TD in relation to risk variables that are peculiar to the MR and others that are shared with psychiatric patient populations. The facility studied provided a unique opportunity to evaluate the effect of drug discontinuation on TD prevalence because a policy had been instituted during the years prior to study initiation which encouraged the discontinuation of neuroleptics. The research team used criterion measures and methodology refined through several studies in psychiatric populations to help in the definition of commonalities and distinctions across these two neuroleptic-treated populations which might provide new information about the pathophysiology of the disorder itself.

Methods

A point prevalence study of TD was carried out among the residents of a state facility

The authors wish to acknowledge the assistance of Frances Simpson and Ida Summers at the Nathan S. Kline Institute and the staff of the Staten Island Developmental Center.

[2] Nathan S. Kline Institute for Psychiatric Research, Orangeburg, NY 10962.

[3] State University of New York at Stony Brook, Stony Brook, NY 11794.

for the developmentally disabled with a total resident population of 721 individuals. All patients who had received a minimum of 1 year's neuroleptic treatment in the 5 years prior to study initiation ($N = 299$) were eligible to be included in the study, providing consent could be obtained. The TD evaluation was performed by using the Simpson Abbreviated Dyskinesia Scale (ADS) (Simpson et al., 1979) and the Abnormal Involuntary Movement Scale (AIMS) (Guy, 1976). The primary criterion measure of TD for the study was a dichotomy based on a global score derived from a subset of ADS items (lip chewing and lateral jaw movements, bon-bon sign, tongue protrusion, choreoathetoid movements of the tongue, cheek puffing, and choreoathetoid movements of the finger/wrists and ankle/toes). This score, which has been described previously (Richardson & Craig, 1982), classified subjects as having TD if they demonstrated evidence of the disorder in the mild-severe range. Other dependent measures employed were a restricted dichotomous global score based on the same ADS subset as above, which classified subjects as having TD only if they achieved a moderate-severe score, a total TD score which was a summation of the scores for the items rated in the global score, and a criterion measure for TD (RD-TD) based on the AIMS scale which required the presence of at least moderate movements in one body area or mild movements in two body areas for a positive TD score (Schooler & Kane, 1983).

Additionally, three data collection instruments were specifically developed for studying this population. The first was a checklist of 66 conditions known to produce mental retardation (Brain, 1977; Robinson & Robinson, 1976) which was completed during the review of the patients' medical records prior to the TD rating. The second was a listing of 19 conditions known to cause retardation whose phenomenology includes neuromuscular symptoms. These conditions were also identified at the time of record review, and descriptions of their associated symptoms were used by the raters during the TD evaluation sessions to aid in differential diagnosis. The third was a checklist of 29 stereotyped movements (such as rocking) and mannerisms reported to be seen in the MR (Baumeister et al., 1980; Meir-Koll & Pohl, 1979; O'Gorman, 1979) for which the patient was rated during the course of the TD evaluation.

A computerized drug-ordering system in place at the facility for approximately 5 years prior to study initiation was used to extract the variables of total number of days on neuroleptics and days off neuroleptics immediately prior to rating day. The complete facility record was studied for each patient, and patient characteristics were extracted and studied as independent variables. These characteristics included: IQ; sex; age; length of time since first facility admission; abusive to self; abusive to others; nonverbal/speech problems; hyperactivity; epilepsy; and neurological problems other than epilepsy. Also included were the DSM-II MR etiological categories of: Infection and/or Intoxication; Trauma or Physical Agent; Disorders of Metabolism, Nutrition or Growth; Gross Brain Disease (postnatal); Unknown Prenatal Influence; Chromosomal Abnormality; Prematurity; Major Psychiatric Disorder; and Psychosocial Deprivation.

A reliability study on the Simpson ADS and the AIMS was performed between the first author and the primary rater (G.H.) among psychiatric inpatients ($N = 25$) with satisfactory results (Kappas .633–.744; Pearson r's .788-.925). The first phase of the project consisted of a pilot study ($N = 19$) during which the first author rated concurrently with the primary rater. During this phase, it was determined that the validity of the ratings would be enhanced by observing the patients in their usual settings (i.e., dayroom, classroom) with an evaluation session of approximately 30 minutes. During the course of the study, 55% of the study population were rated twice; first, by the primary rater alone and then at a second session by both raters with the first author blind to the first rating, and with a consensual rating of both raters obtained at that second session.

Statistical methods used to analyze the data included chi-square analysis for categorical variables and the t-test statistic for continuous variables. Multivariate analyses were carried out using stepwise linear discriminant function analyses for the dichotomous dependent variables (Dixon et al., 1981; Nie et al., 1975) and a multiple linear regression was used for the continuous TD measure.

Results

Consents were obtained for 211 of the 299 eligible patients (70.6%). Chi-square analyses performed comparing the study population to the 88 clients for whom consents were not obtained on the variables of sex, age and DSM-II categories of retardation levels (mild, moderate, severe, or profound) revealed no significant differences. Of the 211 clients studied, 65.9% were male ($N=139$) and 34.1% female ($N=72$). The mean age of the subjects was 35.2 years with the mean length of time since first admission being 27.3 years. The mean IQ for the group was 15.5.

The prevalence of TD using the ADS mild-severe criterion measure was 29.9%. Using this measure, the TD positive group was characterized by a 92% rate of buccolingual-masticatory movements and an 80% rate of mild abnormal movements in at least two body areas or a moderate movement in at least one body area. The ADS moderate to severe criterion measure yielded a prevalence rate of 15.6% and the AIMS RD/TD, a rate of 48.8%. This latter criterion was highly correlated with the stereotypy, rocking (chi-square = 23.00, $p<.001$) which inflated the prevalence while the other two criterion measures were not affected by these movements (mild-severe, chi-square = 0.22, NS; moderate-severe, chi-square = 1.21, NS). The designation of TD-YES and TD-NO used for the remainder of this paper is based on the ADS mild-severe criterion measure.

The TD-YES group was significantly older than those without TD and significantly more likely to be female (*see* Tables 1 and 2). Residents with TD had experienced longer periods of institutionalization which was primarily an age-related phenomenon as the correlation between age and length of time since first admission was highly significant ($r=.63, p=.0001$).

Variables having to do with neuroleptic use on the day of TD evaluation were significantly associated with TD, while those having to do with neuroleptic history up to that day were not so associated. The rate of neuroleptic use at evaluation was significantly lower for the TD-YES group as was CPZ equivalent dose at evaluation (*see* Tables 1 and 2). These two drug-use variables were significantly correlated ($r=.47, p<.001$). However, the number of days receiving neuroleptics in the 5 years prior to evaluation, and the number of days continuously off neuroleptics prior to rating day for those not receiving medication at evaluation, were not significantly associated with the presence or absence of TD. The time interval off neuroleptics was also studied as a categorical variable with the following breakdown (months): 0-12, 12-24, 24-36, 36-60. There was no significant difference in TD status found for these breakouts (chi-square = 1.915, NS). Of the 84 residents not being treated with neuroleptics at evaluation, 57% had not received that class of drugs for 2 years or more.

The prevalence of TD varied according to DSM-II categories of retardation classified by etiology as shown in Table 1. Two of the categories showed a significant association with TD, one in a positive direction—Disorders of Metabolism, Nutrition, and Growth—and the other in a negative direction—Psychosocial Deprivation.

There was no association between the TD designation and epilepsy, and the category of other neurological problems.

The behavioral characteristics studied also showed no association with TD (abusive to self or others, nonverbal or having speech problems, hyperactivity, and the presence of the stereotyped movements rated).

The results of the stepwise discriminant function analysis carried out on the ADS mild-severe measure as shown in Table 3 indicated that the following variables were significant discriminators for TD (in order of entrance): Age (positive); Disorders of Metabolism, Nutrition, or Growth (positive); Psychosocial Deprivation (negative); and with a marginal association, Sex (female). Group membership was significantly predicted—F $(2.206)=20.28$ $p<.01$, and the resulting canonical correlation was—$R=.53$. Table 3 also shows the classification matrix. This represents the accuracy (77.3%) in classifying each case into either TD-YES or TD-NO groups, compared to actual group membership when using the resultant classification function. A jackknifed procedure was used for internal cross-validity checking which produced an accuracy rate close to the original at 76.3%. Variables that did not reach significance as discriminators in this analysis, though they did show a significant association with TD in the bivariate comparisons were: neuroleptic use at evaluation, CPZ dose at evaluation, and length of time since first admission.

Discussion

The prevalence rate of 30% in this population, using the same phenomenological criteria applied in psychiatric patients, casts doubt on the assertion made by some investigators that TD is closely associated with the disease process of schizophrenia (Crow et al., 1983; Owens & Johnstone, 1982).

This study presents the first reported significant association of TD and age in an MR population. Age has been positively associated with TD in psychiatric inpatients by the current authors with the same criterion measure (Richardson et al., 1984) and by several other investigators in both psychiatric inpatients and outpatients (Kane & Smith, 1982). The commonality of this risk factor between these MR patients and psychiatric populations suggests a similar age factor in the TD vulnerability of both groups.

The status of the risk factor of female sex in this study presents still another similarity to the TD psychiatric literature in which female sex is an acknowledged risk factor but possibly secondary to age (Kane & Smith, 1982). While female sex was significantly associated with TD status in a bivariate comparison, sex entered only as a marginally significant variable in the multivariate analysis where age was highly significant. The sex designation, however, did add to the power of the linear combination to discriminate TD status, and for that reason was kept in the analysis despite its marginal association.

The two diagnostic categories that significantly contributed to the TD discrimination in the multivariate analysis deserve careful study. The category that was positively associ-

ated with TD (Disorders of Metabolism, Nutrition, and Growth) ($N = 12$), was composed primarily of females (75%), had a mean age of 39.9, a mean IQ of 9.2, and a 50% rate of neuroleptic use at a 127.8 mg mean CPZ equivalent dose. The modal medical condition ($N = 7$) in this category was phenylketonuria (PKU). The TD prevalence among the PKU patients was 86% while the prevalence in the remainder of the study population was 27%. All of the 6 PKU patients given a positive TD rating displayed buccolingual/masticatory movements, such as tongue protrusion, choreoathetoid tongue movements, lip movements (pouting, puckering, or smacking), and chewing movements. These patients also displayed other abnormal motor behaviors which were not counted toward the TD designation. These included: rocking, fidgeting, trunk-twisting, self-biting, toe-walking, tension spasms, and surface stroking. Some of these behaviors have been described as part of the symptom picture of PKU (Knox, 1966; Walton, 1977). Despite the small sample size,

TD-YES	28 (44.4%)	35 (55.6%)

this particular vulnerability of PKU cases to develop TD is of interest since it is the first report of a single medical condition being associated with TD. This finding may have heuristic value in terms of the pathophysiology of TD and deserves further study.

The other diagnostic category related to TD, psychosocial deprivation, carried a significant negative association. None of the 16 patients in this category manifested symptoms of TD. The characteristics of this group differed markedly from the prior group (Disorders of Metabolism, Nutrition, or Growth) in that there was a lower rate of females (31%), a younger mean age (32.9), a higher mean IQ (19.3), and a higher rate of neuroleptic use (93.8%) at a higher mean CPZ dose (445.9 mg). Patients were most likely given this diagnosis in the absence of any physical cause for their retardation and in the presence of evidence of nurturance deprivation. This finding could be read as a weak organic risk factor for TD, as this was the category least likely to contain patients with structural brain deficits. The fact, however, that TD was not significantly associated with any of the diagnostic categories indicative of neurological trauma and/or neurological structural deficits such as infection or intoxication, trauma or physical agent, gross brain disease (postnatal), chromosomal abnormality, and prematurity, or medical conditions such as epilepsy or other neurological problems, argues against a strong association of TD and structural neurological impairments.

The lack of association between the primary TD designation (ADS mild-severe) and stereotypies was due to the highly specific phenomenological approach of the criterion measure, the simultaneous rating of well-specified stereotypical movements known to occur in untreated MR patients, and by the rigor of the rating session.

In summary, this study establishes a 30% prevalence of TD in a medically heterogeneous mentally retarded population. Risk-factor analyses demonstrated similarities to the TD psychiatric literature and provided information on the disorder not possible within psychiatric populations.

Neuroleptic-Induced Tardive Dyskinesia and Parkinsonism: Changes During Several Years of Continuing Treatment[1]

Daniel E. Casey, M.D.,[2,3] Uffe J. Povlsen, M.D.,[3] Birgit Meidahl, M.D.,[3] and Jes Gerlach, M.D.[3]

Tardive dyskinesia (TD), a syndrome of abnormal involuntary hyperkinetic movements, usually involves the mouth, tongue, and face, but may also cause choreoathetoid dyskinesias in the limbs and trunk. It occurs in predisposed individuals during or following the cessation of long-term neuroleptic treatment (Casey & Gerlach 1984). Since this disorder may occur in 15% of patients receiving extended neuroleptic therapy—and at even higher rates in the elderly—there is appropriate concern about the proper indications for using these highly effective antipsychotic drugs (Casey, 1985).

Difficult clinical choices must be made when managing patients with TD who benefit from neuroleptic drugs. Since these agents are the purported cause of TD, it is widely believed that they will also inevitably worsen TD if neuroleptic treatment is continued. However, there are few data either to corroborate or refute this commonly held belief. Reports about the natural history of TD noted several possible outcomes, including improvement, stabilization, or aggravation, either with or without continued treatment, but these evaluations tended to be of short duration (Pyke & Seeman, 1981; Schonecker, 1957; Smith et al., 1981; Urhbrand & Faurbye, 1960).

The long-term (5 years or more) outcome of TD has seldom been evaluated. In the few available studies, it was not always possible for the investigators to quantify or monitor the effects of adjustments in drug treatment, such as decreased, stable, or increased dose. Furthermore, changes in other neuroleptic-induced symptoms, such as parkinsonism, were not simultaneously assessed to account for the possible interaction of these two treatment-induced side effects. Therefore, this study evaluated long-term changes in TD and neuroleptic-induced parkinsonism in chronically ill psychiatric patients who required neuroleptic treatment for control of psychosis.

Methods

Patients

Thirty-three patients (6 females, 27 males) with chronic psychiatric illnesses and living in an institutionalized setting were assessed. The mean age was 65.6 years (range, 31 to 99 years).

Medications

The neuroleptic dose for each patient was recorded at the beginning of the evaluation and at 6-month intervals. Drug treatment was tailored to the individual patient's psychiatric needs. Neuroleptic doses were converted to chlorpromazine equivalents (CPZE) (Baldessarini, 1977). Mean daily dose at the end of the study period was 316 mg/day of CPZE (range, 0-1500 mg/day).

Design and Evaluation

Patients were evaluated at the time of entry into the study (baseline) and at one of 3-, 5-, 8-, 10-, or 11-year follow-up assessments in May 1984. A standardized examination for TD and parkinsonism was videotaped at the beginning and end of follow-up assessments. These tapes were randomly sequenced and scored by experienced raters who were blind to the year of assessment and drug treatment. TD was scored on the Abnormal Involuntary Movement Scale (AIMS) (Guy, 1976) and parkinsonism was evaluated with the Sct. Hans Dyskinesia Scale (Gerlach, 1979). TD was defined by the recently proposed research criteria (Schooler & Kane, 1982). Data are presented as changes in group mean total scores.

Results

Over the follow-up period, a consistent pattern of outcome emerged. In the whole group of 33 patients, TD decreased 27% and parkinsonism increased 34% (*see* Table). There was a significant ($p<.05$) positive correlation between length of follow-up and TD improvement. Neuroleptic dosages increased modestly from 265 mg/day to 316 mg/day CPZE (*see* Table). Variable degrees of symptom changes were evident when the treatment was categorized by dosage changes of decreased, stable, and increased. In those patients whose neuroleptic decreased (from 646 mg/day to 230 mg/day) TD was unchanged and parkinsonism increased minimally by 9%. In patients receiving a stable neuroleptic dose (±100 mg/day CPZE average daily dose increased by 9% from 195 mg/day to 214 mg/day); TD decreased 24% and parkinsonism increased 31%. Increased dose (from 128 mg/day to 681 mg/day) was necessary to control psychotic symptoms in some patients. This group showed a 55% decrease in TD and a 21% increase in parkinsonism. In summary, TD remained stable or improved in most patients continuing neuroleptic treatment. No systematic or generalized increase in TD was observed. Furthermore, parkinsonism increased in about the same proportion as TD decreased.

Three of the 33 (9%) patients showed increased AIMS scores, but these were modest changes of +1 to +2 in the total AIMS assessments. These changes were unrelated to treatment status: medicines were discontinued in one patient, dosage was increased by 100 mg/day CPZE in another, and decreased by 75 mg/day in the third. None of these increased scores was of clinical significance and no patient had an increase in global ratings from mild or moderate categories.

Discussion

This study of the long-term outcome of TD indicates that this syndrome remains stable or gradually improves in the majority of patients receiving extended low to moderate neuroleptic dosage. These results are consistent with other studies which have evaluated changes in TD over periods of 5 years or more (Casey & Toenniessen 1983; Gardos et al. 1985; Yagi & Itoh 1984). Furthermore, the few patients who experience increases in TD show only modest changes in symptoms.

The lack of TD aggravating effect by neuroleptics is seen in all the treatment groups. The decreased dose group would be most likely to show an increase in TD, as reduced neuroleptic dose would further unmask existing symptoms and lead to the appearance that TD increased. This was not the case. However, the lack of substantive change in TD at the study end point may be accounted for by offsetting effects of unmasking which would tend to increase symptoms and gradual improvement which would have the effect of decreasing symptoms. The stable dose group provides the best opportunity to evaluate the effects of continuing neuroleptic therapy because the masking or unmasking effects are minimized. The decrement in AIMS scores refutes the proposal that continued neuroleptic treatment will inevitably aggravate TD. Finally, the increased dose group might be expected to show more TD in later years after the initial masking or suppressive effect of neuroleptics was subsequently unmasked by "breakthrough" phenomena. However, this again was not the case.

Some caveats must be emphasized. Most importantly, these conclusions cannot be extended to groups of patients which are substantively different from this study cohort. It is not possible to predict the outcome of a similar study if much higher neuroleptic doses were employed. Similarly, different age groups may have different outcomes. Though increasing age is generally correlat-

TABLE

Changes in Drug Dose, AIMS, and Parkinsonism

ed with decreasing improvement in TD (Casey & Toenniessen, 1983: Smith & Baldessarini, 1980), this group of patients, averaging 65.6 years of age, still showed considerable symptom amelioration over many years. Thus, irreversible TD may not be as pervasive as is widely believed. This time course suggests that combining the concepts of gradually resolving and persisting TD are worthwhile, as TD improvement correlated with length of follow-up.

The role of drug-induced parkinsonism in TD requires further discussion. Other long-term TD investigations have not concomitantly evaluated these syndromes, so opportunities for comparing and contrasting these findings are not yet available. The large majority of patients in this study had coexisting TD and drug-induced parkinsonism, though this point is seldom discussed (Richardson & Craig 1982). The hypothesis that dopaminergic function occurs along a unidimensional continuum of a relative deficit (parkinsonism) to relative excess (TD) is insufficient to explain these coexisting syndromes. However, the inverse changes of TD decrease and parkinsonian increase do support the proposal that these disorders share, at least in part, some reciprocally functioning or dysfunctioning mechanisms. Perhaps the decreased TD is due to a masking bradykinetic effect of parkinsonism.

Increasing age may be an important contributor to the decreasing TD and increasing parkinsonism, as idiopathic parkinsonism occurs with increasing age. Though it is not possible to distinguish whether patients had idiopathic or drug-induced parkinsonism, it must be assumed that patients had at least the drug-induced syndrome because they were receiving neuroleptics. Some of these patients might currently have or eventually go on to develop idiopathic parkinsonism. Furthermore, it may be that the addition of neuroleptics is sufficient to increase subclinical parkinsonism to the level of clinically obvious symptoms, which would subsequently revert to subclinical phenomena if drugs were discontinued.

In summary, TD remains stable or gradually improves in patients receiving long-term, low to moderate dose neuroleptics. TD seldom increases—and then only moderately in this treatment setting. Neuroleptic therapy as an "aggravating agent" of existing TD is unproven. These drugs, at least in conservative doses, are not contraindicated in TD patients with psychosis that is responsive to neuroleptic therapy. TD and parkinsonism change reciprocally, though slowly, over several years. Further study of these coexisting and covarying syndromes is required.

Integrating Incidence and Prevalence of Tardive Dyskinesia[1]

John M. Kane, M.D.,[2] Margaret Woerner, Ph.D.,[2] Michael Borenstein, Ph.D.,[2] James Wegner, Ph.D.,[2] and Jeffrey Lieberman, M.D.[2]

Introduction

Epidemiologic studies of tardive dyskinesia (TD) are important in clarifying the scope of the problem and identifying potential risk factors with the ultimate aim of prevention, i.e., reducing the incidence of the condition.

Considerable difficulty remains, however, in integrating available information. We have previously reviewed the wide range of prevalence estimates in the literature and suggested possible explanations for the degree of variation (Kane & Smith, 1982). Prevalence estimates appear to vary enormously from population to population, and most explanations for this have focused on putative risk factors for the development of the condition. In addition, however, it is also important to consider risk factors contributing to the persistence of the condition once it has developed, since variations between populations in the course of TD will also have an important impact on point prevalence.

In this report we will discuss our current findings with regard to incidence and prevalence in the same population and present some findings with regard to risk factors which might influence the incidence and/or persistence of TD.

Incidence of TD

We have previously reported preliminary findings from an ongoing prospective study of TD development (Kane et al., 1982, 1984). This report presents more recent data analyses for the first 616 neuroleptic-treated patients from the main sample in this study, and for 52 patients entered into the study specifically because they had shown severe extrapyramidal side effects (EPS) to neuroleptic drugs upon examination by the research team.

The Table presents the demographic characteristics of the two groups. The most important feature is that these patients are relatively young and have been followed from early in their treatment course (the median exposure to neuroleptics at study entry is 12 months for the main sample, 5 months for the EPS sample).

Figure 1 displays the results of life-table analyses which present the incidence of TD as a function of time on neuroleptics for the main sample. Three survival curves are plotted on this figure. The first shows the incidence of any TD; the second shows the incidence of TD which persisted for 3 months or more; the third shows the incidence of cases which persisted for 6 months or more.

TABLE

Prospective Study of Tardive Dyskinesia Characteristics of the Neuroleptic-Treated Samples at Study Entry

		Regular Sample ($N = 616$)	EPS Sample ($N = 52$)
Sex:	Male	57%	65%
	Female	43%	35%
Age:	Mean	28	27
	S.D.	10	11
	Range	14-72	16-76
Diagnosis:	Affective Disorder	19%	25%
(Hospital)	Schizoaffective	11%	10%
	Schizophrenia	58%	56%
	Other	12%	9%
Total Months Exposure to Neuroleptics:			
	Mean	22	15
	S.D.	26	20
	Range	0-143	0.25-72
	Median	12	5

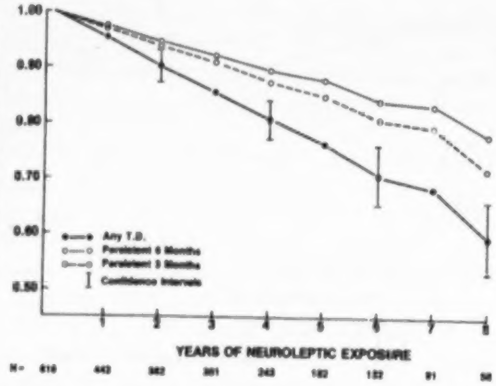

FIGURE 1. Tardive dyskinesia over eight years of neuroleptic exposure.

The overall TD incidence (and 95% confidence intervals) is 18.5% (±4.5%) following 4 years of cumulative exposure to neuroleptics, and 40% (±7%) following 8 years of exposure. The incidence of TD which persists for at least 3 months is 13% (±3%) at 4 years and 29% (±7%) at 8 years. The incidence of TD which persists for at least 6 months is 11% (±3%) at 4 years and 22% (±6%) at 8 years.

The incidence figures presented here are somewhat higher than those we have presented in the past. This is primarily because these figures include data from patients who had TD the first time they were seen (Baseline TD). In the past we had eliminated these cases on the grounds that they had not been followed prospectively, and the point at which they had actually developed TD was not known. However, if we include cases that have *no* TD at baseline and exclude those that do, we will invariably underestimate the incidence. For this reason we have elected to include the Baseline TD cases in the current analyses, and have used their neuroleptic exposure prior to baseline as an estimate of the exposure prior to TD. This does include some error, making the curve higher than it should be. However, we estimate that the amount of this error is small since the Baseline TD cases make up only a third of the TD cases and therefore have a small impact on the total curve.

It is important to note that the hazard rates for any-TD and for persistent-TD appear to be proportional to each other; i.e., there is no evidence that the cases which develop after short exposure are all nonpersistent, while the cases which develop after long exposure are persistent.

Risk Factors for TD

We have conducted a number of analyses with the goal of identifying factors related to the incidence of TD. Except as noted, all analyses were conducted with the 616 patients who either had TD at baseline or were at risk (treated with neuroleptics) while under observation in the prospective study. These analyses are preliminary in nature; in particular, some of the relationships presented here could be due to confounds with other variables which may emerge as the data base increases.

Age. For any given level of exposure to neuroleptics the incidence of TD is higher among older than among younger patients (chi-square = 12.86, $df = 1$, $p = .0003$ by the Wald test). The relationship between age and TD is curvilinear: the risk of TD appears to remain fairly stable through ages 20 to 40, but then rises dramatically with increases in age (chi-square for curvilinear component = 3.72, $df = 1$, $p = .05$). Following 2 years of exposure, the likelihood of TD is about 10% for a 20-year-old and 18% for a 50-year-old patient. Following 4 years of exposure, these figures are 18% for a 20-year-old and 30% for a 50-year-old patient. The value of age as a predictor of TD remains significant when we control for sex (chi-square = 10.13, $df = 1$, $p = .0015$).

Sex. The hazard rate is slightly (but not significantly) higher for women than it is for men (chi-square = 2.20, $df = 1$, $p = .14$). The interaction of sex by age is not significant.

Diagnosis. The incidence of TD was significantly higher among patients diagnosed as affective disorders than it was among either schizoaffectives, paranoid schizophrenics, or other schizophrenics (DSM-II, hospital diagnosis). The most significant distinction was between the pure affective disorders versus the paranoid/other schizophrenics combined. The increased risk associated with the affective disorders in this case remained significant even when we controlled for sex, history of treatment with lithium, electroconvulsive therapy, and age (chi-square = 9.77, *df* = 1, *p* = .002).

Lithium. Within diagnostic category (affective disorder vs. any schizophrenic), prognosis was better for patients who had taken lithium at some point than for those with no history of lithium treatment (chi-square = 5.89, *df* = 1, *p* = .02). Note that lithium use was more common among the affective disorders (43% with history of lithium vs. 9% for schizophrenics), and the affective disorder patients in general appear to have a poor prognosis. Therefore, when we look at lithium without taking diagnosis into account, we find no relationship to incidence (chi-square = 0.61, *df* = 1, *p* = .43).

EPS. The 52 patients who had been entered specifically because of their severe EPS ratings on examination by the research team were compared with the 369 "at-risk" patients who had no history of EPS in their charts (Baseline TD cases were excluded). The TD incidence for the EPS patients is markedly higher than that of the comparison group. Overall the hazard rate for the EPS patients is 2.32 times that of the others (chi-square = 6.64, *df* = 1, *p* = .01), and there is some evidence that the risk ratio could be even higher (3.60) during the first 2 years of exposure. Following 4 years of exposure, the rate of TD is 15% in the comparison group and 37% in the EPS group (Figure 2).

Outcome of TD

Preliminary analyses on the course of TD have been conducted employing data from 96 patients who developed TD during the prospective study.

On the basis of the entire follow-up course, each patient was classified as either remitted, masked, or persistent. A patient was classified as remitted if his global TD ratings were less than 2 (mild TD) for at least two consecutive ratings encompassing at least a 3-month period. A patient could be classified as remitted if these criteria were met, even if the TD later re-emerged. The patient was classified as a "persistent remission" if these criteria were met and the patient never subsequently met criteria for TD. Patients were classified as masked if they met the criteria for remission only following an increase in medication dosage and were classified as persistent if they never met the criteria. In the analyses presented here, the masked cases were treated as persistent.

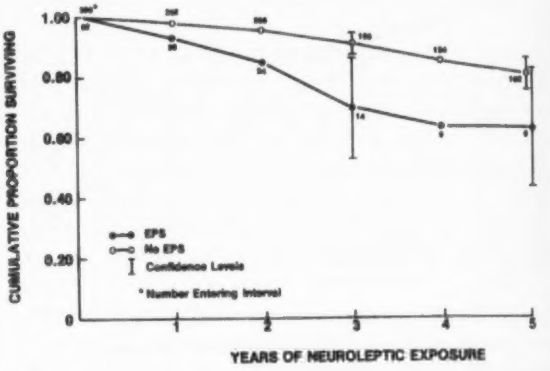

FIGURE 2. EPS as a risk factor for T.D.

Figure 3 presents TD outcome over 2 years of follow-up. When we look at any remissions (ignoring the possibility of a later re-emergence) a total of 32% (95% confidence interval ± 10%) of the patients remit over the first year, and a total of 47% (± 12%) remit over the first 2 years. When we look at persistent remissions only, these figures are 23% (± 10%) for the first year and 33% (± 14%) over the first 2 years.

Exploration of factors related to TD outcome indicate that, as reported based upon earlier analyses (Kane et al., 1984), prognosis is better for patients who develop TD following short-term exposure to neuroleptics than for those who developed TD following long-

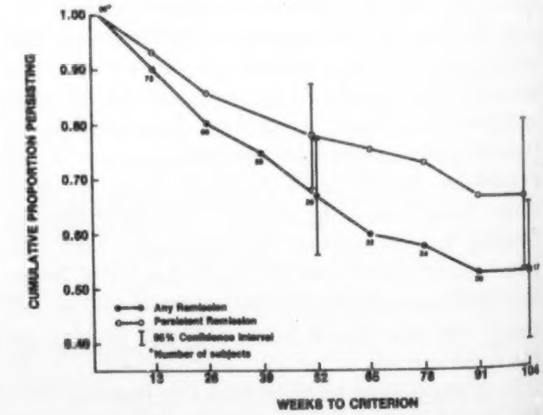

FIGURE 3. Tardive dyskinesia outcome.

er exposure ($p = .05$). There is a suggestion that the importance of prior exposure is greater for women than for men, but gender by itself is not significantly related to TD outcome.

Two measures of treatment after the development of TD have been found to predict outcome: prognosis is better for patients treated with neuroleptics for a smaller proportion of the follow-up period ($p = .05$), and for those treated with lower modal doses during follow-up ($p = .009$). These predictors of outcome are confounded with each other, and with the current sample size it is difficult to identify the unique contribution of each. Thus far, our analyses suggest that modal dose during follow-up is a critical variable with an impact over and above the effect of prior medication history. Proportion of time on medication during follow-up may be more critical for older than younger people; the former appear to have little chance of remitting if maintained on medication after TD develops.

Prevalence of TD

We have recently completed a large-scale survey of the prevalence of TD involving more than 2,000 subjects from two geriatric and three psychiatric populations, including Hillside Hospital. The methodology and some preliminary results were presented previously (Kane et al., 1985; Lieberman et al., 1984a,b). In this report we are focusing on the Hillside sample since the incidence figures discussed above are derived from this population.

Preliminary exploration of variables related to the presence of TD indicated that within each of the psychiatric samples the TD rate increases with increasing age. Further analyses revealed that the impact of age on TD prevalence varies as a function of sex, and of length of exposure to neuroleptics. Figure 4 illustrates the interaction of age and sex in relation to TD prevalence for the Hillside sample. Among women, TD is more prevalent among older than younger people ($r = .42$, $p = .001$). For men, there is a trend in the same direction ($r = .11$, $p = .12$). The fact that this correlation is smaller than the correlation for the women appears to reflect a real fact of risk; that it fails to reach significance for the men reflects in part the relatively narrow age range in the Hillside sample.

The other side of this coin is that sex is more important as a risk factor in older people than it is in younger people. Whether or not sex will prove significant as a risk factor depends upon the age range of the sample; in the Hillside sample it is significant. The following p values were obtained using multiple regression analysis: main effect for sex, $p = .036$; main effect for age, $p = .001$; interaction, $p = .012$.

Figure 5 graphs TD prevalence as a function of the interaction of age and length of neuroleptic exposure in the Hillside sample. It is evident that for the younger people (age<30) there is only a small increase in the probability of getting TD with longer expo-

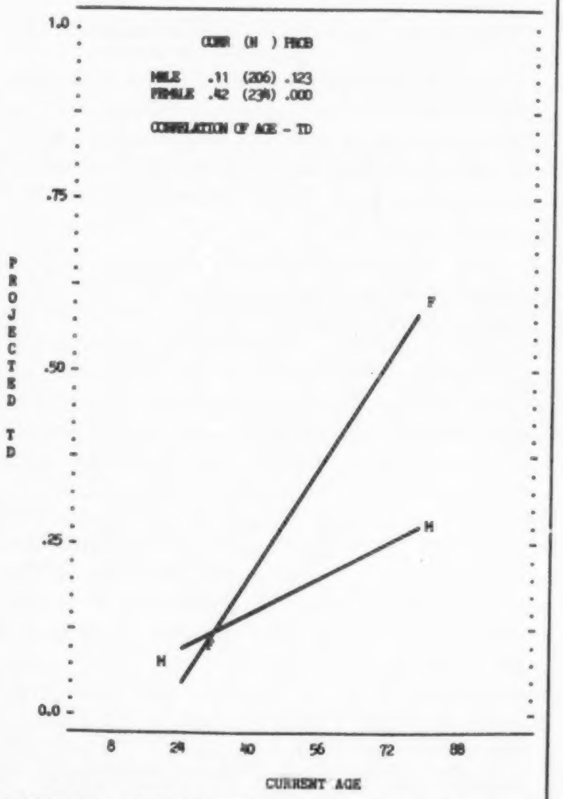

FIGURE 4. Hillside: TD as a function of age and sex.

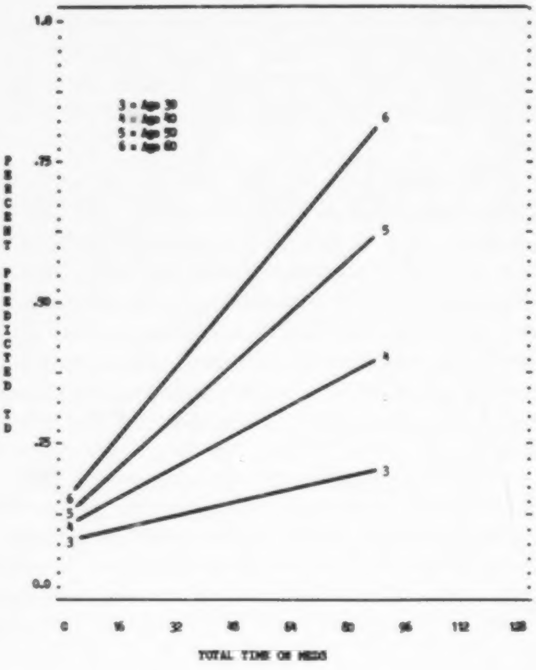

FIGURE 5. TD as a function of duration and age.

sure to neuroleptics, while for the older people TD prevalence increases sharply with increased exposure. The regression analysis yielded the following *p* values: main effect for age = .001; main effect for exposure = .019; interaction = .016.

It seems likely that the interaction reflects, in part, the fact that duration of exposure is truly a more important factor in TD development among older, than among younger people. However, this interaction could also partly reflect the findings presented above, from our study of outcome of TD among patients in the incidence study. Since the data under discussion stem from a prevalence survey, we do not know how long the individuals have had TD; i.e., how old they actually were when TD developed, and what length of drug exposure preceded it. However, it is clear that the duration of exposure employed in the analyses includes not only neuroleptic treatment *prior* to TD, but also some treatment *following* TD development. Our preliminary findings with regard to TD outcome suggest that treatment with neuroleptics following TD development is a more critical factor in TD persistence among older, than younger people. Thus, we would expect that even if the impact of neuroleptic exposure on the *development* of TD were equal across all ages, the TD would be less likely to remit, and *prevalence* would therefore be higher, among the older people.

Discussion

Our data suggest that the integration of incidence and prevalence requires knowledge about risk factors for the development of TD and risk factors for the persistence of TD once it develops. Certain findings are of particular clinical importance. Older individuals are not only more vulnerable to developing TD but also more likely to have it persist if neuroleptic medication is continued. Prognosis of TD is better for those patients treated for a smaller proportion of time during the follow-up period and for those treated with lower modal doses during follow-up.

By developing strategies to reduce the risk of TD in vulnerable individuals, and to increase the likelihood of a favorable outcome in those who have developed TD, we may be able to make meaningful progress in reducing the extent of this problem.

A Five-Year Follow-up Study of Tardive Dyskinesia

Guy Chouinard, M.D., M.Sc.(Pharmacol), F.R.C.P.(C), F.A.P.A.,[1,2,3] Lawrence Annable, B.Sc., Dip.Stat.,[1,2] Pierre Mercier, Ph.D.,[1,2] and Andree Ross-Chouinard, M.D.[1,2]

Introduction

Prevalence studies of tardive dyskinesia (TD) in neuroleptic-treated patients have investigated factors associated with the presence of the disorder. The most reliable finding is that TD is more prevalent in older patients. In 1975, we carried out a cross-sectional study of TD in all 256 schizophrenic patients receiving neuroleptic maintenance treatment in the outpatient clinic of the Allan Memorial Institute (Chouinard et. al, 1979b). At that time, we reported the prevalence of TD in the clinic to be 31% (in fact, 23% met the recently proposed Schooler and Kane research diagnostic criteria for TD) (1982). Stepwise multiple logistic regression analysis suggested the following risk factors for TD (in order of statistical significance): advanced age, long records of hospitalization, poor therapeutic response to neuroleptics, and fluphenazine medication [oral or intramuscular (i.m.)]. There was also an inverse relationship between parkinsonism and TD, patients tending to have one or the other disorder but usually not both.

We now report a 5-year follow-up of these patients, focusing in particular on an investigation of factors related to the subsequent development of TD in a cohort of 131 patients who did not present the disorder in 1975.

Method

In 1975 TD and parkinsonism were assessed by a neurologist (A.R.-C.) in all 256 schizophrenic outpatients receiving maintenance antipsychotic medication in the Special Follow-Up Clinic of the Allan Memorial Institute. The scale used was the Extrapyramidal Symptom Rating Scale (ESRS) of Chouinard and Ross-Chouinard (Chouinard et al., 1979a, 1980), and the presence of TD was determined according to the Schooler and Kane Research Criteria (1982) which require at least moderate dyskinetic movements in one body area or mild dyskinetic movements in two body areas. The presence of parkinsonism was also determined on a similar basis. Psychopathology was assessed by one of the authors (G.C.) who conducted a psychiatric interview. The schizophrenic illness of patients was classified as good or poor prognosis using the World Health Organization (WHO) scale for prognosis. Data were collected on demographic characteristics, treatment history, neuroleptic type and dosage converted to chlorpromazine equivalents (Davis, 1980), and antiparkinsonian drugs. Patients with a history of meningitis, brain trauma, neurosyphilis, or an abnormality on neurological examination associated with a neurological disease were classified by the neurologist as having brain damage.

In 1980, 169 of the original cohort of 256 patients (65%) were reassessed by the same neurologist and psychiatrist after 5 years of further neuroleptic treatment, using the same rating scales and criteria as before. At this time it was confirmed that all patients met the DSM-III criteria for schizophrenia. Eighty-seven of the original 256 patients (35%) were lost to follow-up because of either failure to return to the clinic, transfer elsewhere, or death. Table 1 compares the characteristics of patients lost to follow-up with those of patients who were reassessed in

1980. Patients lost to follow-up were more likely to be male ($p = 0.07$), younger (mean difference = 3 years, $p = 0.06$), treated for a shorter period of time (mean difference = 2.5 years, $p = 0.001$), less likely to have brain damage ($p = 0.05$), and more likely to be receiving antiparkinsonian medication ($p = 0.10$). There were no significant differences between the two groups, however, with respect to prevalence of TD or parkinsonism in 1975.

TABLE 2

Patient Characteristics: Cohort of 131 Patients With No TD in 1975

	1975		1980
Men/Women		61/70	
Age	40 (23-67)[a]		45 (27-72)[a]

i.m. only	18%		60%
p.o. and i.m.	16%		5%
Antiparkinsonian medication	53%		68%

[a] Median (minimum - maximum).

The characteristics of the cohort of 131 patients who did not present TD in 1975 and who were reassessed in 1980 are shown in Table 2. During this period the policy in the clinic was to switch patients from daily oral (p.o.) neuroleptics to long-acting i.m. neuroleptics (mostly fluphenazine enanthate or decanoate) if feasible. Antiparkinsonian medication was prescribed only if necessary and not prophylactically. Polypharmacy was avoided as far as possible. The principal changes in treatment may be summarized as follows: 1) there was a switch from p.o. to i.m. medication in 45% of patients; 2) a reduction in neuroleptic dosage (chlorpromazine equivalents) (Davis, 1980) in 48% of patients;

and 3) an increase in antiparkinsonian dosage in 45% of patients.

Results

Prevalence of TD in all reassessed patients (N = 169). Table 3 shows the prevalence of TD (Schooler & Kane, 1982) and parkinsonism in the 169 patients assessed in both 1975 and 1980. The prevalence of TD increased from 22% to 44% ($p<0.001$, McNemar's test) and that of parkinsonism from 33% to 72% ($p<0.001$, McNemar's test). There was no significant ($p<0.05$) difference between the sexes with respect to the prevalence of either TD or parkinsonism on either occasion. There was, however, a tendency ($p<.10$, $\chi^2 = 3.65$) for more parkinsonism in men than women in 1975, but not in 1980.

Development of TD in reassessed patients (N = 131). In the cohort of 131 patients who did not present TD in 1975, 46 patients (35%) developed TD, while the prevalence of parkinsonism increased from 32% to 71%. Stepwise multiple logistic regression analysis (Kleinbaum et al., 1982) was used to predict the development of TD (coded 0,1) during the period 1975 to 1980. The exploratory variables included for selection were of two types: those thought to be of possible etiological significance in the development of TD, and those known or suspected to uncover covert TD. The etiological variables included were: sex, age, duration of neuroleptic treatment (dichotomized and coded as follows: 0 = <5 yrs. 1 = ≥5 yrs), schizophrenic prognosis (0 = good, 1 = poor), brain damage (0 = none, 1 = present), and parkinsonism score (1975); the uncovering or confounding variables were: reduction in neuroleptic dosage, switch from daily p.o. to long-acting i.m. neuroleptic (the uncovering mechanism may be through a decline in blood level at the end of the injection interval when all patients were assessed), and an increase in antiparkinsonian dosage.

The model building strategy used was to start with all main effects in the model and then carry out forward selection to add any significant second-order product (i.e., interaction) terms (Kleinbaum et al., 1982). Second-order product terms were considered because we were unable to obtain a good fit with main effects only. An alpha level of 5% was used throughout. Because there were nine main effects and 36 second-order interaction terms as candidates for selection, this analysis should be regarded as exploratory, particularly where variables of marginal statistical significance were selected.

The results of the stepwise logistic regression analysis are shown in Table 4. Three main effects were significant at the 5% level: parkinsonism score (1975), poor schizophrenic prognosis, and treatment duration (>5 years). Also, two variables were significant at the 10% level: a switch from p.o. to i.m. medication and a neuroleptic dosage reduction. In addition to these main effects two interac-

TABLE 4

Variables Related to Development of TD (1975–1980): Results of Stepwise Logistic Regression Analysis ($N = 131$)

Variable	Coefficient	S.E.	χ^2	p
Intercept	−5.07	1.43	12.58	0.0004
Parkinsonism score (1975)	0.13	0.06	4.68	0.03
Poor schizophrenic prognosis	1.09	0.53	4.31	0.04
Treatment duration	1.42	0.73	3.75	0.05
p.o. to i.m. switch	1.12	0.61	3.37	0.07

[a] Negative coefficient indicates that effect of presence of both risk factors is less than sum of each main effect (lack of additivity).

TABLE 5

Predictive Ability of Multiple Logistic Regression Model

		Predicted (1980)		
		No TD	TD	Total
	No TD	75	10	85
True	TD	23	23	46
(1980)	Total	98	33	131

Sensitivity (true positives) = 50%
Specificity (true negatives) = 88%

tion terms were added to the model: 1) that between the medication switch and parkinsonism score with a negative coefficient ($p = 0.008$), indicating that the risk of TD with both factors present is less than the sum of their separate risks and, more specifically, that the patients most at risk for developing TD were those with high parkinsonism scores in 1975 who remained on the same medication type (either p.o. only or i.m.) in 1980; and 2) that between an antiparkinsonian dosage increase and brain damage with a positive coefficient ($p<0.05$), indicating that brain-damaged patients were more vulnerable to the effect of antiparkinsonian increase. The effects of age and sex were not significant ($p>0.10$), although it is worth noting that age and duration of treatment were correlated somewhat ($r = 0.44$, $p<0.001$). We examined the goodness-of-fit of this model by comparing the predicted cases ($p>0.5$) with the true cases of TD (Table 5): sensitivity (true positives) was 50% which is fair, and specificity (true negatives) was 88%, which is good.

Because the 1975 parkinsonism score appeared to be the best predictor of subsequent TD development, we repeated the stepwise logistic regression analysis including the change in parkinsonism score (1975 to 1980) as an additional variable. The results of this analysis were that the new variable, change in parkinsonism score, became the best predictor of TD development ($p = 0.001$) with 1975 parkinsonism score second. The new model increased the sensitivity of prediction to 54% while the specificity remained at 88%.

Annual incidence rate of TD. The 5-year cumulative incidence rate of TD in the cohort of 131 patients who did not present TD at the 1975 assessment was 35% (46/131). This is equivalent to a mean annual incidence rate of 8.4% (Kleinbaum et al., 1982). However, this does not consider remissions (or misclassifications) among patients who presented TD in 1975 but not in 1980 of which there were 9/38 cases representing a 5-year cumulative remission rate of 24% or a mean annual remission rate of 5.5%. Thus the mean annual incidence rate of TD corrected for remissions was 2.9%.

Discussion

These results suggest that three etiologic factors may be important in the development of TD. The presence of severe parkinsonism which cannot be suppressed by antiparkinsonian medication appeared to be a precursor of TD development. There was also evidence that worsening of parkinsonism was associated with TD development. Whereas in 1975 we observed an inverse relationship between parkinsonism and TD, in 1980 both disorders were commonly present simultaneously. During this interval the patients had both grown older and been exposed to more neuroleptic treatment, so that a more advanced stage of extrapyramidal movement disorder had probably been reached. One contribution to the changed relationship may have been the decrease in dopamine synthesis with aging, especially in male patients, as found in PET scan studies.

The second risk factor for TD was poor schizophrenic prognosis, which tends to confirm our earlier finding (Chouinard et al., 1979b) of an association between poor therapeutic response to neuroleptics and TD. Duration of neuroleptic treatment also appeared to be a risk factor with 5 to 10 years of exposure being a critical period. This finding has intuitive appeal but has not generally been substantiated in prevalence surveys. The correlation between treatment duration and age in the present population probably explains why we failed to find age an important predictor here, although it was the first variable selected in our 1975 prevalence survey (Chouinard et al., 1979b). Another factor to be considered is that these patients may constitute a special subgroup inasmuch as they were those patients in the clinic who did not present TD in 1975, despite presence of risk factors in some cases.

Three variables that may perhaps be characterized as uncovering or, in statistical terminology, confounding factors rather than etiologic factors were also identified as associated with the manifestation of TD: a switch from p.o. to i.m. medication in those without parkinsonism, a neuroleptic dosage reduction, and an increase in antiparkinsonian medication in brain-damaged patients. The explanation for the appearance of the medication switch as a risk factor may be that blood levels tend to decline toward the end of the injection interval (when all these patients were assessed), and a decline in dopamine receptor blockade at this point would tend to uncover any covert dyskinesia. This may be the explanation for our previous finding of an association between fluphenazine treatment and TD (Chouinard et al., 1979b) as many patients were receiving i.m. fluphenazine. A study in two patients using neuroleptic radioreceptor assay measurements of neuroleptic blood levels at different points during the injection period supports this view (Chouinard et al., 1982). The uncovering effect on TD of neuroleptic dosage reduction is well-known: that of anticholinergic antiparkinsonian dosage increase has also been documented (for example, Chouinard et al., 1979c), but the finding of increased vulnerability of brain-damaged patients in this respect is new. In our earlier prevalence study of TD (Chouinard et al., 1979b) in this population, we found that brain-damaged patients tended to have more severe forms of TD than those without brain damage. Thus, there seems to be some evidence to suspect that brain-damaged patients are at greater risk for the disorder.

The estimated 2.9% annual incidence rate of TD corrected for remissions is similar to that reported by Kane et al. (1982) from a prospective study of TD development, although the latter study is of a younger and heterogeneous population of patients with schizophrenia or manic-depressive disorder.

We believe that a large-scale prospective study of TD development in a homogeneous population of newly-treated schizophrenic patients would clarify further the risk factors.

Plasma Fluphenazine Levels in Patients Receiving Two Doses of Fluphenazine Decanoate[1]

Stephen R. Marder, M.D.,[2] John W. Hubbard, Ph.D.,[3] Theodore Van Putten, M.D.,[2] Edward M. Hawes, Ph.D.,[3] Gordon McKay, Ph.D.,[3] Jim Mintz, Ph.D.,[2] Philip R.A. May, M.D.,[2] and Kamal K. Midha, Ph.D.[3]

Plasma level monitoring has the potential for being particularly useful in maintenance treatment. One of the serious problems in selecting a maintenance dose is that there are few guidelines available for deciding when a particular dose is adequate for a particular patient. This differs from the treatment of acute schizophrenia in that the clinician may not be able to titrate dose against active signs and symptoms. In this regard, anything which would help make dose selection in maintenance therapy less of a trial-and-error proposition would be welcome.

We explored the usefulness of plasma fluphenazine levels in the context of a double-blind comparison of what we defined as a very low (5 mg) and a conventional dose (25 mg) of fluphenazine decanoate (FD) administered every 14 days over a 1-year period (Marder et al., 1984).

Method

The subjects were 45 men referred to an outpatient research clinic at a large urban V.A. hospital. All were diagnosed as suffering from a Schizophrenic Disorder using DSM-III. The design of this study is described in detail in a prior publication (Marder et al., 1984).

After giving written informed consent, subjects were managed on a stable dose of FD for 2 or more months. Individuals who could not be stabilized on 25 mg or less every 14 days were dropped from the study. Following stabilization, all neuroleptics were stopped for 4 weeks. (This actually entailed missing one injection of FD.) At this point, all subjects were given a test dose of 5 mg of FD. Blood for plasma level measurement was drawn before and 24 hours after the injection. Two weeks after the test dose, patients were randomized to a double-blind trial of 5 or 25 mg of FD administered every 14 days. For the 5 mg group, FD was prepared in miglyoil; for the 25 mg group, in sesame seed oil. Further blood samples were drawn at 1, 2, 3, 6, 9, and 12 months following entry. Samples were drawn 2 weeks following the previous injection or just before the next injection was administered.

Plasma levels of fluphenazine were measured using a radioimmunoassay (RIA) (Midha et al., 1980) which was validated for specificity using gas chromatography with mass spectrophotometry (Dudley et al., 1983).

When patients demonstrated a worsening of 3 or more points on Brief Psychiatric Rating Scale (BPRS) cluster scores for thought disturbance or paranoia, they were considered to have a psychotic relapse. Most were rather mild and easily managed by adjusting the drug dose. (Relapses in this report were designated exacerbations in a prior publication.)

Results

The Figure describes the mean fluphenazine concentrations for patients treated with the two doses. Patients were dropped from this analysis when their dosage was adjusted as a result of relapse. Thus, the *N*'s reflect a diminishing sample due to dropout and relapse. However, results based only on com-

FIGURE. Mean plasma fluphenazine levels for patients treated with 5 or 25 ng of FD every 14 days. Differences between the two dosage groups are statistically significant at 8 weeks and thereafter.

plete cases through 52 weeks looked virtually identical. Although the values were similar at baseline and 2 weeks, by 8 weeks fluphenazine levels were significantly higher for patients treated with 25 mg—and remained significantly higher for the remainder of the year. For clarity, the standard deviations were left off this Figure. They were very large—often larger than the means. Levels for the 5 mg group remained reasonably stable over the year whereas the 25 mg group required 3 to 6 months to reach a stable level. Even though the high dose patients received fivefold the dose of low dose patients, there was some overlap.

We also examined the relationship between steady-state fluphenazine concentrations and vulnerability to psychotic relapse. We used the concentrations at 6 months since this was the amount of time it took plasma concentrations to reach steady state. We compared these levels with psychotic relapses during the next 18 months. The mean fluphenazine level was 0.57 ng/ml for relapsers and 1.01 ng/ml for nonrelapsers. This difference, however, was not statistically significant. Although 5 of the 10 patients who eventually relapsed had plasma levels below 0.5 ng/ml, 7 of the 19 patients who did not relapse were also in this range. None of the patients with plasma levels of greater than 1.5 ng/ml relapsed.

We also studied the relationships between fluphenazine levels at 3 months and side effects. Plasma concentrations correlated with the score for Akinesia ($r = .52$, $p = .002$), the BPRS cluster score for Retardation ($r = .52$, $p = .002$), and Total BPRS ($r = .39$, $p = .02$).

The relationship between side effects and plasma level was also examined in a pooled within-subject analysis of the ratings of side effects and fluphenazine levels over all rating occasions. For this analysis, "dummy" variables were forced into a hierarchical analysis of the side effect ratings to remove between-subject effects. We then computed the amount of variance which was explained by the addition of information about either fluphenazine (FLU) or log (FLU+1). For the log-transformed FLU, the relationship approached statistical significance at the $p = .097$ level for akinesia and reached significance at the $p = .016$ level for akathisia.

Discussion

We found that patients who received 25 mg of FD every 14 days required from 3 to 6 months to reach a stable steady state. This finding indicates that a dose of FD which may be appropriate during the first weeks of treatment may be excessive a few months later. It suggests that when a higher dose is given for maintenance, a reasonable practice might be to gradually decrease the dose or increase the interinjection interval during the first 6 months of treatment.

Although plasma fluphenazine concentrations were lower in patients who eventually relapsed, this difference did not reach statistical significance. Finding relationships between plasma concentration and clinical response probably requires a larger sample size when studying maintenance treatment as opposed to acute treatment. This is because of the greater variance related to such factors as the lengthy period of time during which patients may be exposed to environmental stressors and the unpredictable relationship between the time a dose is altered and the time to relapse. Our findings, however, do suggest that patients who have plasma levels of greater than 1.5 ng/ml are less likely to relapse than those with much lower plasma levels. The correlations between plasma levels and side effects suggest that this added protection may be at the cost of more personal discomfort. This finding is consistent with a previous report on the same population in which patients treated with 25 mg had higher side effect ratings than those treated with 5 mg—even though both groups were treated aggressively with antiparkinson medications (Marder et al., 1984). This suggests that finding the best maintenance dose may require a complex risk-benefit analysis in which the amount of protection given to the patient should be weighed against the amount of side effect-induced discomfort that the person can tolerate.

In conclusion, our data do not indicate that the measurement of fluphenazine level alone will be helpful in determining whether a patient is more vulnerable to relapse. Finding a reasonable threshold plasma level may require the measurement of parent fluphenazine as well as its psychoactive metabolites or the development of an even more sensitive analytical method. We did find, however, that plasma level measurement may be useful in determining when a patient is receiving too much drug. The correlations between fluphenazine levels and side effects indicate that patients with high plasma levels may benefit from having their drug dose reduced.

An Early Phase II Clinical Trial of Remoxipride in Schizophrenia With Measurement of Plasma Neuroleptic Activity

Guy Chouinard, M.D., M.Sc. (Pharmacol), F.R.C.P.(C),[1,2] and L. Turnier, M.D.[2]

A wide variety of chemical classes of drugs such as phenothiazines, thioxanthenes, butyrophenones, diphenylbutylpiperidines, and benzamides have been found to have antischizophrenic effects. Relative in vitro affinities for D_1 and D_2 dopamine receptors differentiate classical antipsychotics such as fluphenazine (relatively equivalent in blocking D_1 and D_2 receptors) from butyrophenones and diphenylbutylpiperidines. Haloperidol and pimozide, for example, have respectively 200 and 900 times more affinity for D_2 than D_1 receptors (Christensen et al., 1984). It is interesting to note that remoxipride, a new substituted benzamide, has no known affinity for D_1 receptors, and thus appears to be a selective D_2 receptor-blocking agent (Ogren et al., 1983). In addition, remoxipride was found to have a preferential effect in mesolimbic and extrastriatal dopamine containing neurons (Ogren et al., 1983). Remoxipride is an S(-)-3-bromo-N-[1-ethyl-2-pyrrolidinyl) methyl]-2,6-dimethoxy-benzamide monohydrate. We report an early Phase-II clinical trial of remoxipride in the treatment of chronic schizophrenia with and without acute exacerbation.

Method

Twenty patients satisfying the study criteria given below were selected for inclusion in the trial and transferred to our research ward of Hôpital Louis-H. Lafontaine. The selection criteria required that: 1) the patients be aged between 18 and 65 years; 2) a primary hospital diagnosis of schizophrenia be confirmed by the research psychiatrist on the basis of the DSM-III (American Psychiatric Association, 1980); and 3) patients with physical illness, childhood schizophrenia, organic brain syndrome, mental retardation, alcoholism, epilepsy, or drug addiction and women of childbearing potential be excluded from the study.

The study population consisted of 13 men and 7 women aged between 27 and 62 years (median: 48 years), who had been hospitalized on 1 to 18 occasions (median: 6), for a total duration of 2 to 30 years (median: 10.6 years). The schizophrenic disorder was classified by DSM-III criteria as paranoid in 13 patients, undifferentiated in 3 patients, and disorganized in 4 patients, of which 14 cases were chronic without acute exacerbation and 6 chronic with acute exacerbation.

Before entering the trial, all patients were receiving haloperidol (6 to 80 mg/day, median: 30) and a central anticholinergic antiparkinsonian, procyclidine (7.5–40 mg/day, median: 22.5). No other psychotropic drugs were taken by the patients before entering the trial. Haloperidol was abruptly discontinued and patients underwent a 4-day placebo single-blind washout period during which procyclidine was gradually decreased and discontinued.

Patients were then treated for 6 weeks with remoxipride at dosages determined according to therapeutic effect and side effects. The medication was given in the form of tablets prepared in a dosage strength of 50 mg and was administered in a twice-daily regimen. The initial dose varied between 50 mg and 100 mg/day. Thereafter, the dosage was adjusted according to therapeutic effect with the condition that individual dose increments did not exceed 100 mg/day and did not occur at intervals of less than 3 days.

Assessment of symptoms was based on

clinical interviews conducted by a single clinical investigator (G.C.). Mental status was scored on admission (while on haloperidol), at the end of washout (day 0) and weekly on the Brief Psychiatric Rating Scale (BPRS) (Overall & Gorham, 1962) and a 7-point Clinical Global Impression (CGI) severity of illness. Factor scores were formed from the items of the BPRS (Overall & Klett, 1972). Extrapyramidal symptoms were recorded weekly on the Extrapyramidal Symptom Rating Scale of Chouinard and Ross-Chouinard (Chouinard et al., 1980, 1984); biochemistry, urinalysis, hematology, EEG, and ECG were done at regular intervals. Blood samples were taken in a fasting state before and 1 hour after ingestion of the morning dose of medication for measurement of plasma remoxipride concentrations and neuroleptic levels. Plasma neuroleptic activity was determined using a radioreceptor technique developed by Creese and Snyder (1977), Lader (1980), and Cohen et al. (1980), and remoxipride blood concentrations by a high performance-liquid chromatography method.

Results

Drug Dosages

Dosages of remoxipride were increased gradually from 50 mg/day to a maximum of 500 mg/day (the maximum daily dose permitted was 600 mg). At week 6 the doses varied between 75 mg/day and 500 mg/day (median: 225 mg/day). Eleven of the 20 patients were administered minimal doses of clonazepam, as needed, for agitation ($n = 8$), insomnia ($n = 2$), anxiety ($n = 1$), and aggressiveness ($n = 1$) that was not well-controlled by the study medication; the mean daily dosages of clonazepam in these patients ranged from .05 to .57 mg (median: .09 mg). Upon admission to the trial, all patients were receiving procyclidine to control parkinsonian symptoms (mean: 23.1 mg/day) while at the end of the treatment period with remoxipride 15 patients (75%) required procyclidine administration (mean: 17.4 mg/day). Comparison of week 6 and pre-washout doses of procyclidine shows a trend to a decline (paired t test, $t = 1.8$, $p < .10$, two-tailed) in patients' need for antiparkinsonian medication. No other psychotropic drugs were given during the trial.

Therapeutic Effect

All patients completed 42 days of active treatment. The Table shows the mean admission, baseline and weekly scores for all patients on the BPRS and CGI. There was a statistically significant deterioration (paired t test, $p < .001$) at the end of placebo washout in the BPRS total score and statistically significant improvement occurred at the end of the treatment period in the CGI (paired t: 2.8, $p = .01$, two-tailed) and the BPRS total score ($t = 2.3$, $p = .03$). The response of each patient was classified on a 7-point scale ranging from very much worse to very much im-

proved: 16 patients were considered to be improved (10 much improved, 6 minimally improved), and 4 patients minimally worse.

Extrapyramidal Symptoms and Adverse Effects

The admission, baseline, and weekly mean scores for parkinsonism and tardive dyskinesia (TD) on the Extrapyramidal Symptom Rating Scale are also shown in the Table. There was a decline in parkinsonism at Week 6 compared to admission while patients were on haloperidol treatment. Comparison of Week 6 with baseline scores shows a significant decline (paired *t* test: 2.65, *p* = .02, two-tailed) in hyperkinetic parkinsonian symptoms (factor formed by adding scores for tremors and akathisia) during remoxipride treatment. There was a tendency for an increase of overt TD in the total score for dyskinetic movements at baseline when patients had been withdrawn from neuroleptics compared to admission (when patients were on haloperidol); thus, after 6 weeks of drug administration remoxipride appeared to have little masking effect on TD.

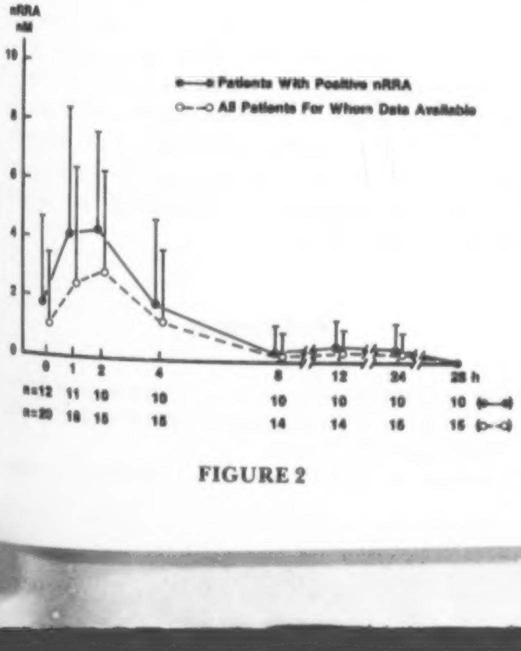

FIGURE 2

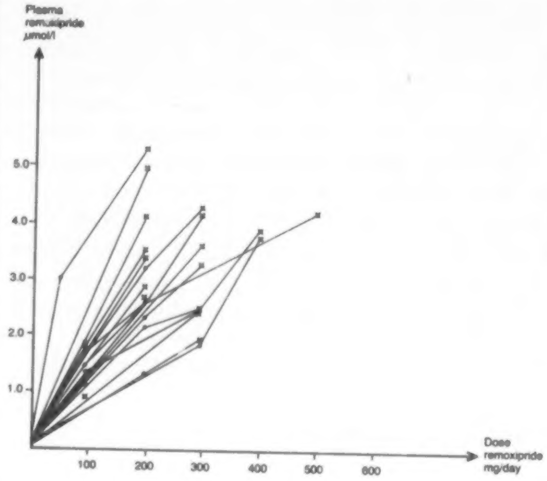

FIGURE 3

The following adverse experiences (of moderate intensity) were judged to be related to the study drug (number of cases in parentheses): akathisia (9), fatigue (7), insomnia (7). Remoxipride produced a statistically significant ($p<.05$, paired *t* test) lowering of the supine systolic blood pressure at the end of the clinical trial (mean admission—120.3 mm Hg, Day 42—111.8 mm Hg). There was a statistically significant ($p<.001$, paired *t* test) but small decrease in the mean body weight at the end of the trial (from 67.1 kg at admission to 65.1 kg at the end of the trial). Eight patients (40%) at the beginning of the clinical trial had mild EEG abnormalities, probably related to their prior neuroleptic intake. Of

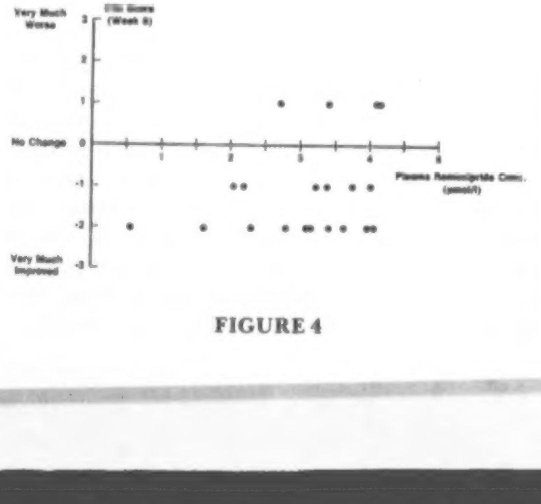

FIGURE 4

these patients, 2 had an improvement and 2 no changes, while in the 4 other patients there was some evidence of remoxipride producing EEG effects: mild irregular bitemporal theta activity, paroxystic activity induced by photic stimulation and increases in slow activity. On the ECG remoxipride produced nonspecific ST-T wave changes in 6 patients. Transient changes in white blood cell count (inversion of the proportion of neutrophiles upon lymphocytes) were noticed in 2 patients and transient vacuoles in lymphocytes (<1%) were observed in 3 patients.

Plasma Radioreceptor Activity

Baseline and day 42 blood samples were analyzed for neuroleptic activity using calf caudate homogenate and [^{3}H]spiperone as ligand. Activity was detected in the plasma of 5 patients at baseline (end of washout), whereas little or no activity could be demonstrated in the samples obtained on day 42. Indeed, analysis of serial blood samples drawn at 1, 2, 4, 8, 12, 24, and 28 hours after the last morning dose on day 42 showed 12 patients with maximum concentrations ranging from 1.7 to 12.3 nmol/l (median: 3) and 8 patients with no activity. Blood samples were analyzed in quadruplicate and the limit of the assay was 6 nmol/l haloperidol units. Results presented are the means of the four measurements (Figures 1 and 2).

Plasma Concentrations of Remoxipride

Serial plasma remoxipride concentrations in individual patients were measured following the last dose of remoxipride (Day 42). Maximum concentrations occurred within 2 hours after drug intake and ranged between 1.8 μmol/l (50 mg dose) and 10.8 μmol/l (250 mg dose). The mean elimination half-life was 5.9 hours (range: 4.1-10.7 hours). When individual patient steady-state plasma remoxipride concentrations were plotted against dose, steady-state concentration and dose were linearly related (Figure 3). There was no evidence of correlation between plasma remoxipride concentrations or drug dosage and therapeutic effect (Figures 4 and 5).

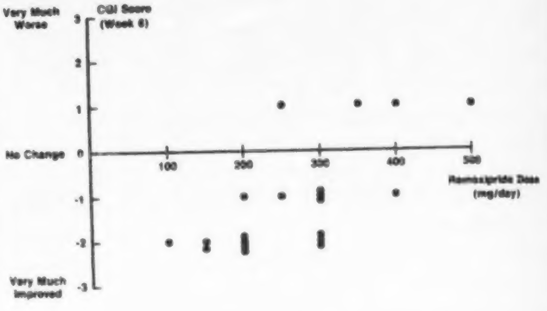

FIGURE 5

Discussion

The marked improvement seen in half of these schizophrenic patients suggests that remoxipride has an anti-schizophrenic effect. The decline in parkinsonism is consistent with the hypothesis that remoxipride has less effect on the nigrostriatal system (Ogren et al., 1983). Remoxipride was found to have little masking effect on TD. By the same token, this might suggest that remoxipride would have correspondingly less potential to induce TD in newly treated patients, but this would need to be investigated. The lack of serum neuroleptic activity in the majority of blood samples shows that the drug has low affinity for [^{3}H]spiperone binding which makes this method less useful for neuroleptic activity measurements, due to its low sensitivity versus remoxipride, when using calf caudate. Remoxipride can act with a configuration of the receptor other than the one labelled with spiroperidol, thus ligands such as [^{3}H]n-propylnorapomorphine could be used for D_2 receptors in human studies of remoxipride. These results underline the importance of a drug's D_2-dopamine receptor-blocking properties in achieving an anti-schizophrenic effect.

Measuring Adverse Drug Reactions in a Postmarketing Surveillance System[1]

Seymour Fisher, Ph.D.,[2] Stephen G. Bryant, Pharm. D.,[2] and Ronica M. Kluge, M.D.[3]

We have recently initiated a large-scale study aimed at developing new methods for collecting postmarketing surveillance data on prescription drug experiences in an ambulatory population. These new monitoring methods are designed to complement rather than replace existing physician-initiated voluntary reporting of adverse drug reactions (ADRs). The current study, while primarily oriented toward validating a patient-initiated monitoring system, actually compares two different approaches to ADR surveillance. One is based upon patient-initiated reports via toll-free telephone to a cadre of interviewers who have been trained to record in a standardized way the relevant information obtained from the patient. The second method utilizes computer-directed similar telephone interviews initiated by the interviewing staff.

Since many practitioners and researchers use some form of clinical interview to elicit potential ADRs, it is important to examine the validity of such interview information. These interviews may range from a casual inquiry about how the patient has been feeling since starting the drug to a detailed review of organ systems (e.g., Maclay et al., 1984: Mellinger, 1984: Rauch, 1979). The purpose of this paper is to show that, while spontaneously reported symptoms are uniformly reliable in detecting ADRs, symptoms elicited by system review may lead to gross overestimation of true ADRs.

Method

The study is based upon a cohort of patients receiving a new prescription for certain targeted drugs. The target drugs were selected from two classes of therapeutic agents with markedly disparate, well-documented ADR profiles (tricyclic antidepressants and antibiotics).

Study Design

At the time a targeted prescription is being dispensed at our outpatient pharmacies, cooperation is randomly solicited from half of the patients (Experimentals) via a printed notice attached to the outside of their medication bag: this patient package "outsert" provides a brief, concise statement of what the patient is being requested to do, the reason for the request, and a removable sticker (to be placed on the bathroom mirror or elsewhere) that gives our toll-free number along with a summary of details about how to report "*any* new or unusual symptoms" during the next 2 weeks. The other half of the patients (Controls) do not receive any outsert, but are interviewed approximately 2 weeks later by telephone. These Control interviews are computer-directed so that the questions and various response options appearing on the interviewer's video screen are almost completely determined by the patient's prior responses.

The Standardized Interview

If the ultimate goal is to be able to reliably detect the occurrence of postmarketing ADRs, then—as noted by Lasagna (1971) and Wardell et al. (1979)—the first step must be the development of a standardized method of collecting accurate reports of new or unusual "adverse clinical events" (ACEs) during or following a drug's use. An ACE

may or may not turn out to be an ADR, depending upon additional information that permits inferences about potential causality; but all ADRs must first be valid ACEs.

When a call from an Experimental patient is received, or when we initiate a call to a Control patient, the ensuing interview tries to obtain complete information about all ACEs being reported. The standardized interview used to identify, describe, and quantify ACEs was developed from modifications of SAFTEE, the National Institute of Mental Health's "Systematic Assessment For Treatment Emergent Events" (Levine & Schooler, 1984). The modified telephone interview has four sections: a general inquiry for spontaneously reported ACEs, a systematic ACE inquiry, a post-spontaneous inquiry, and a medication inquiry.

The opening questions center only on spontaneously reported ACEs. With patient-initiated calls from Experimentals, the interviewer records verbatim the symptom(s) that prompted the patient to call. In staff-initiated Control interviews, the key initial question is simply "Have you noticed any new or unusual symptoms during the past 10 days or so?" For each symptom spontaneously mentioned by the patient, the interviewer records details about its onset, duration, frequency, pattern, and severity.

The general inquiry is followed by a systematic inquiry covering each of the specific organ systems or areas relevant to the two target drug classes. Special emphasis is again placed on eliciting only recent unusual changes: e.g., "Have you noticed any changes in your skin during the past 10 days or so?"; "Have you had any unusual problems with your mouth or tongue?" When a "No" response is elicited to any of these system-review questions, the interviewer does not pursue the area any further for fear of encouraging over-reporting through suggestion (i.e., unlike the original SAFTEE interview, we avoid asking leading questions like "Has your mouth been dry?" or "Have you had any rashes?").

At the end of the systematic inquiry the patient is offered one more opportunity to recall any other unusual changes. The final part of the interview then determines when the patient most recently started the target medicine; whether it is still being taken and with any significant dosage changes; whether and when it had been used previously; what other medicines were being taken regularly; and—if one or more ACEs were reported—whether starting the drug unequivocally preceded each ACE onset, and whether the patient attributed the new symptoms to any of the medications.

Data Analyses

The data presented here are based on 231 staff-initiated, computer-directed interviews with Control patients who a) were over 18 years old, b) did not receive an outsert or any other indication at the pharmacy of study participation, and c) when interviewed approximately 2 weeks later, reported having started the target drug and were not taking any drug from the other target class. The sample had a mean age of 45.0 years (s.d. = 15.6); 81.8% were female; 53.6% were Caucasian (38.9% were Black, 6.9% were Hispanic).

As noted previously, all ADRs must first be valid ACEs. A valid ACE is defined as any untoward reaction that began only after the patient started the target drug and within the specific allowable 14-day reporting period. A patient could have reported one or more valid ACEs during the general inquiry, the systematic inquiry, or the post-spontaneous inquiry; these ACEs are referred to as Spontaneous, Systematic, and Post-Spontaneous ACEs, respectively. In addition, because there is general agreement on a core set of expected side effects for the antibiotics and tricyclic antidepressants constituting our target drugs, we can single out those valid ACEs matching one of our assumed "true adverse drug reactions." Table 1 lists the symptoms defined as antibiotic and tricyclic ADRs prior to the study and reported by our Control patients in the three interview sections. Any one of the nine antibiotic ADRs reported by an antibiotic patient was recorded as an ACE+; similarly, any of the 12 tricyclic ADRs reported by a tricyclic patient was also recorded as ACE+. Conversely, any of the antibiotic ADRs reported by a tricyclic patient, or any of the tricyclic ADRs reported

TABLE 1

Pre-defined Adverse Drug Reactions[a]

Antibiotics[b]	Tricyclic Antidepressants[b]
Sore mouth	Dry mouth
Sore tongue	Daytime drowsiness or excessive sleeping
Itching	Light-headedness or dizziness
Rash	Fainting
Hives	Rapid or irregular heartbeat
Stomach ache or pain	Blurred vision
Nausea or vomiting	Headache or head pain
Cramps	Shakiness or tremor
Diarrhea	Constipation
	Delay in starting urination
	Decreased force of urine stream
	Numbness or tingling (extremity)

[a] These common adverse drug reactions were selected from Long (1977), USP (1983), and the approved labeling.

[b] Antibiotics: ampicillin, doxycycline, penicillin, tetracycline; tricyclics: amitriptyline, doxepin, imipramine.

by an antibiotic patient, are shown as ACE−'s.

Obviously, these pre-defined ADRs are not unique to the two target drug classes. However, since their ADR profiles have little overlap, and since patients could not be taking drugs from both classes concomitantly, in effect we have reduced the likelihood that our tricyclic patients would experience an antibiotic ADR or our antibiotic patients would experience a tricyclic ADR. It follows then that a) most of the true ADRs will be a subset of reported ACE+'s; b) true ADRs should be found where there are a minimum of ACE−'s, and c) therefore we can create an indicator of ADR sensitivity by comparing the presence of ACE+'s relative to ACE−'s within any defined group of patients:

$$\text{ADR Index} = \frac{(\text{ACE}+) - (\text{ACE}-)}{(\text{ACE}+) + (\text{ACE}-)}$$

This index can range from 1.00 (reflecting maximum sensitivity of a system in detecting the pre-defined ADRs) through 0.00 to −1.00 (indicating the extent to which ACE−'s are obscuring ADR detection).

In order to be able to conclude with a high level of confidence that a particular ACE was caused by a particular drug and is therefore a true ADR, it is first necessary to rule out attribution of the ACE to any one of the alternative causes listed in Table 2. Note that since the only condition under which no ACE−'s would be expected is when all six competing categories of potential causes can be ruled out (e.g., via statistical adjustment in a randomized controlled study), the primary validity tests are limited to whether a mean ADR Index is significantly positive or whether one mean is significantly larger (i.e., more sensitive) than another.

Results

Table 3 gives the frequency and rate per hundred of the 151 patients who had one or more valid ACEs. Each patient was classified as having either no valid ACEs or at least one valid ACE. Within each drug class ADR incidence estimates are first based upon ACEs reported anywhere in the interview, and are then shown cumulatively beginning with spontaneously reported ACE+'s during the general inquiry, and proceeding through the systematically elicited ACE+'s to the post-spontaneously reported ACE+'s.

Looking at the total group we see that almost two-thirds (65.4%) of all patients at some point in the interview reported at least one new or unusual symptom that appeared within 2 weeks after starting their target medication. When we limit the analysis to only ACE+'s (representing matches with a true ADR), we find that 30 to 40% of the patients are reporting symptoms that could indeed be true ADRs. Table 3 then shows in which sec-

TABLE 2

Competing Hypotheses to Account for an Adverse Clinical Event (ACE)

1. Natural course of the primary illness for which the target drug was prescribed.
2. Natural complications of the primary illness.
3. Onset of a new illness.
4. Independent environmental factors capable of producing the ACE.
5. Placebo effects associated with starting the target drug.
6. Other medications, foods, or substances taken concomitantly with the target drug.

TABLE 3

Frequency of Patients With One or More Valid ACEs

	Antibiotics		Tricyclics		Total	
	N	Rate*	N	Rate*	N	Rate*
Total Interviews	132		99		231	
Any ACE	89	67.4	62	62.6	151	65.4
Any ACE+	43	32.6	39	39.4	82	35.5
Spontaneous ACE+	23	17.4	11	11.1	34	14.7
Systematic ACE+	19	14.4	25	25.3	44	19.0
(cumulative)	42	31.8	36	36.4	78	33.8
Post-Spontaneous ACE+	1	0.8	3	3.0	4	1.7
(cumulative)	43	32.6	39	39.4	82	35.5

*Per 100 patients

tions of the interview these ACE+'s were elicited.

Spontaneous ACE+s reported during the general inquiry yielded only about a 15% incidence overall. However, when ACE+'s subsequently elicited during the systematic inquiry are added to the incidence rates obtained from the general inquiry alone, the overall rate is markedly increased: almost doubled for the antibiotics, and tripled for the tricyclics.

The final post-spontaneous inquiry augments the estimated incidence rates only slightly. Fewer than 2% of the total sample reported an ACE+ here when they had not already done so in either the general or systematic inquiry.

Thus, depending upon whether you focus on all ACEs, or only upon ACE+'s, and depending upon whether you base your estimates on the total interview or just the initial general inquiry, ADR incidences for these target drugs could range from a high of 67% to a low of less than 15%. To determine whether ACE+'s reported anywhere in the interview are equally valid, it is necessary to examine how ACE−'s are being reported along with ACE+'s. Table 4 presents these data for each of the three interview sections. During the general inquiry there were more patients in both drug classes with at least one spontaneous ACE+ than there were patients with one or more spontaneous ACE−'s. Although there were disproportionately more ACE− patients in the antibiotic group, the ADR Index means of .19 and .38 (not significantly different) indicate that both antibiotic and tricyclic groups were accurately discriminating true ADRs: the pooled mean ADR Index of .25 is significantly different from zero at the .03 level.

When we turn to the systematic inquiry, however, something is strikingly awry. The mean ADR Index for the total group is .00, stemming from very different results in the antibiotic and tricyclic samples. While tricyclic patients continued to discriminate as well as previously, an extraordinarily large number (32) of the antibiotic patients who had not spontaneously reported an ACE+ are now reporting ACE−'s, overwhelming the 19 patients now reporting one or more ACE+'s. The mean ADR Index for the antibiotics is negative and significantly different from the mean ADR Index of .42 for the tricyclics. Obviously, many of the pre-defined ADRs from the tricyclic target drug profile were being elicited from antibiotic patients throughout the systematic inquiry, even when they were reporting few new true antibiotic ADRs. Since there were three more pre-defined tricyclic ADRs than antibiotic ADRs, one has to consider the possibility that

TABLE 4

ADR Index for Different Interview Sections

	Antibiotics	Tricyclics	Total
Spontaneous ACEs			
Patients with at least 1 ACE+ or 1 ACE−	30	16	46
At least 1 ACE+	23	11	34
At least 1 ACE−	16	5	21
Mean ADR Index*	.19	.38	.25
t (df = 44)		<1 (p = N.S.)	
Systematic ACEs			
At least 1 ACE+ or 1 ACE−	40	30	70
At least 1 ACE+	19	25	44
At least 1 ACE−	32	12	44
Mean ADR Index	−.31	.42	.00
t (df = 68)		3.75 (p < .001)	
Post-Spontaneous ACEs			
At least 1 ACE+ or 1 ACE−	2	4	6
At least 1 ACE+	1	3	4
At least 1 ACE−	1	2	3
Mean ADR Index	.00	.25	.17
t (df = 4)		<1 (p = N.S.)	

*For each patient who had at least one ACE+ or one ACE−, an individual ADR Index is calculated based upon the total number of ACE+s and ACE−s reported by that patient. A different ADR Index, calculated by subtracting the frequency of patients with at least one ACE− from the frequency of patients with at least one ACE+ and dividing by the combined frequencies, yields almost identical results.
N.S. — Not Significant

antibiotic patients had more opportunity by chance to report an ACE that matched one of the tricyclic ADRs. However, that same opportunity was present for spontaneous ACEs during the general inquiry.

Table 4 further shows that during the final post-spontaneous inquiry only 6 patients mentioned an ACE+ or an ACE− for the first time. Despite the extremely small numbers, the data yield a tricyclic positive ADR Index consistent with accurate ADR detection while the two antibiotic patients, after having completed the systematic inquiry, yield an ADR Index of zero.

Discussion

We are not aware of any other postmarketing surveillance study that has so closely and systematically examined the incidence of *all* new symptoms during a 10- to 14-day period following the start of a drug. One of the clearest findings emerging from this study is that almost two-thirds of our patients did report a new ACE, and even when limiting the analysis to known ADRs, we find between 30% and 40% of our patients reported at least one "true" ADR (ACE+) at some point in the interview. The fundamental issue here centers on two interrelated questions: whether ACEs reported anywhere in the interview are equally likely to be ADRs, and whether the true ADR incidence for these target drugs is therefore really as high as is estimated by the total interview.

Our results clearly indicate that ADRs can be accurately detected for antibiotics and tricyclics using spontaneously reported ACEs, with incidence estimates of 17.4% and 11.1%, respectively. ACEs elicited by systematic inquiry increase the incidence estimates substantially, but totally destroy the discrimination of true antibiotic ADRs. On the other hand, tricyclic ADRs were effectively detected in all segments of the interview, and while the total estimate of 39.4% is within the range estimated by Klein et al. (1980), these authors qualify their figures by noting "that the data on (antidepressant) side effects are often confusing and show great variation from study to study."

Although it can be argued that only a comprehensive interview can detect possible ADRs, a systematic review of organ systems may be highly prone to eliciting ACEs consisting of more noise than signal. Huskisson & Wojtulewski (1974) have shown that inflated incidence estimates can occur and true side effects can be obscured when specific checklist questions are asked. But even without a checklist litany, a likely mechanism by which spurious ACEs may get unwittingly introduced is found in the realization that simply asking repeated "non-leading" questions focusing on possible side effects can exert subtle demands to reply positively—not so much by remembering distinctive symptoms that the patient forgot to report spontaneously, but by calling up perceptions associated with the illness or other drug-irrelevant causes. In the present study, out of 21 antibiotic patients reporting "decreased appetite," 19 were elicited during the systematic inquiry!

While our results do not unequivocally imply that incidence estimates based upon a systematic inquiry will necessarily overestimate the true incidence, the finding that inclusion of these ACEs drastically impaired the accurate detection of true antibiotic ADRs should dictate extreme caution for the investigator who is attempting either to detect new ADRs or to estimate true ADR incidences. Spontaneously reported ACEs appear to be the most reliable source for uncovering ADRs, although the actual population incidences may sometimes thereby be underestimated.

Estazolam in the Treatment of Insomnia

Roberto A. Dominguez, M.D.,[1] Burton J. Goldstein, M.D.,[1] Alan F. Jacobson, Ph.D.,[1] and Richard M. Steinbook, M.D.[1]

In many cases of insomnia no overt medical, pharmacologic, or psychiatric cause can be found to explain this symptom. A poor sleep pattern often interferes with daytime activities. When non-pharmacologic treatments have been ineffective or insufficient, the judicious intermittent use of hypnotics is indicated. Hypnotics are most helpful when the disturbed sleep pattern is transient, as in acute situational reactions, hospitalization, jet lag, or after changes in work schedule. Because of their higher therapeutic index, lesser potential for abuse, and superior effectiveness, the benzodiazepines have replaced the barbiturates as the modern hypnotics. Three are currently marketed in the United States, and they differ in their pharmacokinetic profile and metabolism.

Estazolam is the generic name of a new triazolobenzodiazepine marketed in Japan since 1975 and presently under development as a hypnotic in the United States (*see* Figure). After single 2.0 mg oral doses, estazolam appears in the plasma within 30 minutes, and its mean peak plasma level occurs after 2.6 hours. Its mean elimination half-life is about 15 hours (Allen et al., 1983). It produces no long-acting metabolites or hepatic microsomal enzyme induction. After multiple doses, its accumulation is complete within 3 days. Placebo-controlled polysomnographic studies have demonstrated the hypnotic efficacy of estazolam in doses of 2 mg (Roehrs et al., 1983). Other clinical studies have confirmed its short-term efficacy in various doses against placebo (Walsh et al., 1984). This trial had as its objective the systematic assessment of estazolam's hypnotic efficacy and side-effect profile in comparison to flurazepam (Dalmane®) and placebo.

This was a double-blind, randomized study, using balanced parallel placebo and active control groups. Patients were assigned to receive either estazolam 2.0 mg, flurazepam 30 mg, or placebo and instructed to take the medication 30 minutes prior to bedtime for 7 consecutive nights. The trial was conducted in outpatient symptomatic volunteers (Brauzer & Goldstein, 1973). The demographics and presenting complaints of symptomatic volunteers are similar to those patients who are prescribed most hypnotics by their family physician. Subjects had to be in good health, had to be free from emotional or substance abuse disorders, and had to abstain from sedatives for at least 2 weeks. The inclusive age range was 21 to 65 years.

All patients suffered from at least a 3-month history of subjective complaints of insomnia. Those eligible for the study reported a history of daytime distress associated with insomnia plus an estimated total sleep time of 6 hours or less. Additionally, all patients complained of at least one of the following symptoms: a) difficulty in falling asleep of 60 minutes or more; or b) at least three nocturnal awakenings, or at least 1 hour of wakefulness during the night. A detailed written in-

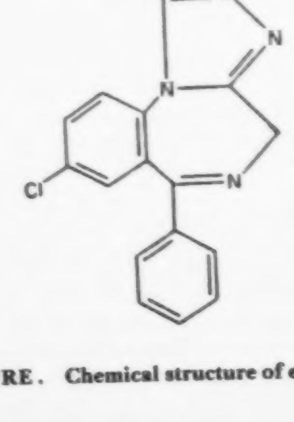

FIGURE. Chemical structure of estazolam.

TABLE 1

Global Evaluation of Efficacy Results

	Treatment Comparison *P*-values		
	E vs. P	F vs. P	F vs. E
Sleep latency	0.008(E)[a]	0.006(F)[a]	0.966(NS)
Sleep duration	<0.001(E)[b]	<0.001(F)[b]	0.930(NS)
Nocturnal awakenings	<0.001(E)[b]	<0.001(F)[b]	0.425(NS)
Depth of sleep	<0.001(E)[b]	<0.001(F)[b]	0.587(NS)
Quality of sleep	<0.001(E)[b]	0.083(F)[c]	0.004(E)[a]
Overall improvement	<0.001(E)[b]	<0.001(F)[b]	0.289(NS)

[a, b, and c] indicate a significant difference at the 0.10, 0.01, 0.001 levels, respectively. The significant better treatment is indicated in parentheses.

Abbreviations: E = Estazolam, F = Flurazepam, P = placebo

formed consent was signed by each patient during the screening interview. Pre-study evaluations for eligibility were performed within 4 days prior to drug administration. Medications that could influence sleep were prohibited. Alcohol, caffeinated beverages, and napping were discouraged. Physical examinations and laboratory tests were performed at the screening visit and within 3 days of the last study dose. Also a comprehensive drug screen was obtained at baseline. Two questionnaires were completed by each patient each morning of the study, beginning on the morning after the first dose. During the final visit the investigator reviewed the study questionnaires with each patient and a global evaluation was made of efficacy and side effects. Drug compliance was confirmed by history, completed questionnaires, and a pill count during the final visit.

Seventy-four patients were screened and started the double-blind study. Four did not return for the final visit. Another 5 patients (2 on estazolam, 1 on flurazepam, and 2 on placebo) had a positive urine drug screen at baseline and their efficacy results were excluded from the analysis. Thus, data from 65 patients (20 on estazolam, 24 on flurazepam, 21 on placebo) were used for the efficacy analysis. Many patients deviated from the instructions given them relating to bedtime habits and ingestion of caffeinated and alcoholic beverages. Approximately 60% of the patients did not take their medication 30 minutes prior to bedtime or deviated from their stated usual bedtime by 1 hour at least one night during the study. Additionally some patients took caffeinated beverages (51%), or alcohol (54%), or napped (61%) at least once during the study. Data from these patients were included in the efficacy analysis on the basis that they closely resemble the general hypnotic-taking population, and the occurrence of these deviations was balanced among treatment groups. Statistical analysis showed the three treatments groups to be comparable with respect to all major demographic variables. All groups were also comparable at baseline regarding estimated sleep variables.

Global evaluations completed by the investigators demonstrated that both active treatments were significantly superior to placebo in all measurements used to assess quantity of sleep ($p<.01$). There were no significant differences between the active treatment groups (Table 1). A global rating of "quality of sleep" reflected how rested and refreshed patients reported they felt upon arising. Estazolam proved superior to placebo ($p<.001$) but improvement in the flurazepam group failed to reach significance ($p=.083$). In this measure estazolam was preferred over flurazepam ($p=.004$).

Results from the patient's daily sleep questionnaires paralleled those of the global assessments. Collective mean scores from the 7 treatment nights showed that both estazolam and flurazepam significantly reduced the number of nocturnal awakenings ($p<.01$), improved the total length of sleep, plus the depth and quality of sleep (all p's$<.001$). There were no significant differences among the active treatments. Patients reported that their length of time to fall asleep did not improve as much as other measures. Overall improvement in estimated sleep latency only showed a trend in favor of estazolam

TABLE 2

Headaches	1	1	1
Bitter taste	0	3	0
Irritability	0	2	0
Others	3	3	2
Total	21	41	5

($p = .088$) and flurazepam ($p = .093$) over placebo.

More patients reported adverse effects with flurazepam (83%) than with estazolam (50%). Residual daytime drowsiness and fatigue accounted for approximately 70% of all side effects reported for both active treatment groups. A significantly greater ratio of patients on estazolam ($p<.005$) and flurazepam ($p<.0001$) reported side effects than on placebo. Also, a significantly greater ratio of patients reported side effects on flurazepam than on estazolam ($p = .017$). Perhaps the most important measurement of side effects was a global assessment by the investigators of their severity (Table 2). There was no statistically significant difference in the global evaluations of side effects between estazolam and placebo treated patients, or between both active treatments. However, there was a significant difference ($p = .0018$) between flurazepam- and placebo-treated patients. Comparison of baseline and final vital signs and laboratory studies did not show any clinical or statistical significance.

As discussed, patients on both active treatment groups reported that their length of time to fall asleep did not improve as much as other measures. In interpreting this finding, it is important to note that most patients enrolled in this study (73%) complained of sleep maintenance problems, rather than a sleep latency disturbance. Therefore, given this population, it is not surprising that neither estazolam nor flurazepam treatment resulted in a statistical improvement in sleep latency. This interpretation is consistent with that of another published report (Roehrs et al., 1983) which concluded that the lack of statistical improvement of complaints of sleep latency with estazolam when compared to placebo was not surprising in a patient population in which 47% did not have an objective disturbance in sleep latency.

Not only does this study strongly confirm the hypnotic efficacy of estazolam, but it also shows that the new drug is better tolerated than flurazepam. In the literature, residual daytime effects have been more frequently reported with flurazepam than with other intermediate half-life benzodiazepines (Bliwise et al., 1984; Fillingim, 1982; Wesnes & Warburton, 1984). In the assessment used to measure how refreshed and rested each subject felt upon arising, estazolam was favored over flurazepam. Treatment-related side effects were less frequent with estazolam (Table 3). Also, the overall severity of these reactions favored the new drug. Additionally, significantly fewer patients complained of any side effects with estazolam than with flurazepam.

Microcomputer Database Management Systems Concepts

David Robert Gastfriend, M.D.[1]

In the years since 1977, when microcomputers first became commercially available, the database management system (DBMS) has proven to be an efficient, cost-effective tool for clinical research. Microcomputer DBMS software programs are widely available commercially, offer a variety of powerful functions, and provide a range of ease of operation to suit any researcher, from the technophobe to the hacker. The selection of a particular DBMS for clinical research depends upon several factors, such as what kind of data will be stored, how much data will be stored, how the data storage will be organized, what kinds of analyses will be performed on the data, and whether more than one user will need to use the database at the same time.

What Is a Database? (Wiederhold, 1981)

At its simplest, a database is *a filing system.* Like a file card box for article references, or a Rolodex device for phone numbers, it is a tool for storing any data worth retrieving later. These examples have limited usefulness, however, because they use a physical structure to organize data.

Consider the situation in which one has each patient's name, address, and identification number listed vertically in that order on a Rolodex card, and the Rolodex deck is organized in alphabetical order by patient's last name. If it also became necessary to be able to look up patients just by identification numbers, one solution would be to photocopy each card, cut out the identification number line, paste it in at the top of a new card, then place the cards in the second Rolodex holder in numerical sequence. This example points out the limitations of a system that uses a physical layout to organize data. A computerized database would do this electronically and would allow both types of Rolodex card to be printed once the basic data are entered.

A computerized DBMS stores data in files, or lists, with a minimum of duplication. Each list can be used for a variety of purposes, because the program can reorganize it with relative independence of any physical layout. The *location* of any individual piece of data is indicated internally as a symbolic reference point rather than a physical reference point. This makes it possible a) to rearrange data to create a variety of useful reports with it; b) to perform complex searches called *queries*; and c) to add new types of data elements subsequently within existing records.

---

[1] Department of Psychiatry, Massachusetts General Hospital, Boston, MA 02114.

What Is "Data"?

The design of a computerized database begins by *listing what data are needed* for storage and analysis. The current range of microcomputer DBMS software makes it possible to store various kinds of data. Most DBMS programs are adept at managing numbers, formulae, and alphabetical characters, while a few have special qualities that treat words, sentences, paragraphs, and pictures (such as digitized drawings, x-rays, and scans) as discrete data elements.

How Are Data Represented in the Computer?

Data are represented by a set of microscopic switches which can exist in either a high or low voltage state (on or off). If a switch is off, this corresponds to 0; if it is left on, it stands for 1. Each switch is the electronic equivalent of a base two, or binary, digit. In computerese, a *binary digit* is called a *bit*.

Since real data elements are not adequately represented by only a 0 or 1, several bits are needed to represent the whole range of characters in use. There are about 100 distinct keys on the typewriter, including the digits from 0 to 9, all the characters in the alphabet, and punctuation symbols.

How many bits are required in order to represent all of these characters of real data? If we allot two bits per character, this allows us to represent four distinct characters: 0, 1, 2, and 3 (by the binary codes 00, 01, 10, and 11, respectively). Therefore, a set of 7 bits is needed in order to represent 100 distinct characters, and another bit is used as a marker for accuracy—altogether 8 bits. This set of 8 bits is the smallest number of switches that will represent all the decimal system characters, the alphabet, and punctuation symbols. Each *set of 8 bits* is called a *byte*. The coding system for all these characters is standardized throughout all microcomputers, and is called ASCII (pronounced "AS-key," for American Standard Code for Information Interchange).

Calculation of Data Storage Needs for a Study

Just as file cabinets vary in size, number of drawers, capacity, etc., DBMS programs vary in how much data can be stored. It is necessary to understand how data elements are stored and to calculate the total data storage needs a study will require, prospectively. For example, consider the design of a database for a study of the dose response to lithium. In order to represent a single lithium level, a value which can range from 0.0 to 9.9, the computer will need to allocate one byte for each digit, or two bytes per level to be stored. (The decimal point will be handled differently than a digit and need not be counted here.)

Each patient gets varying doses of lithium, and each week, for 10 weeks, each patient has lithium levels drawn and several rating scales recorded. The file containing all the study data will contain a record for each patient, and at the conclusion of the study each record will contain 10 different lithium levels, 1 for each week of the study. Since each lithium level will take up 2 bytes, this data field alone will use 20 bytes per patient. If 100 patients will participate in the study, we will be storing 2,000 bytes, or 2 kilobytes (K) of data just for this one variable. The variable, lithium dose, ranges from 0 to approximately 3,000 mg/day, for a total of 4 bytes (or characters) times 10 recordings times 100 patients. For this variable, then, we'll be storing another 4K of data. If we add a few scales on each patient, we must be careful in planning ahead of time how much data we will want to be storing. Here is a sample calculation:

$$5\ \frac{\text{scales}}{\text{subject}} \times 15\ \frac{\text{questions}}{\text{scale}} \times 2\ \frac{\text{characters}}{\text{question}} \times 10\ \text{weeks} \times 100\ \frac{\text{subjects}}{\text{week}} = 150{,}000\ \text{characters} = 150\text{K bytes}$$

Steps in Using Database Management

All database management systems operate using the same basic steps of 1) data and file definition, 2) data entry, and 3) data retrieval (Figure 1). Once one understands these in operation on one DBMS program, it becomes relatively easy to learn another program.

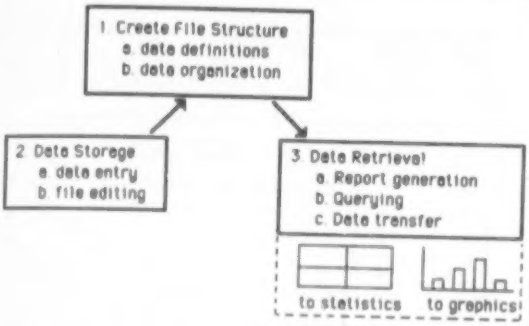

FIGURE 1. Steps in using database management.

The first and most important step in using a DBMS package is data and file definition. This consists of analyzing what data a study will gather, and defining and restricting which data items will be stored in order to construct what is known as a *data dictionary*. The data dictionary is a list of the data elements that will be stored, the *form* of data elements (e.g., "00/00/00" for dates), as well as the *content* of each element (so that a date of 11/35/85 should be excluded if the data dictionary is complete in its description of form and content of a date element).

Once the data dictionary is complete, data items can be organized into a database structure. To create a Rolodex file like the one above, each item must be stored in a set place whose location has to be defined (analogous to row and column of the Rolodex card). Every program has limits as to how many different data elements can be stored in a patient's record, how many records in a file. Therefore, in addition to the initial calculation of total data storage needs (shown above), it is necessary to map out whether one file will be sufficient to hold all data elements, or whether it will better to break up the data into several files—demographic data, medication data, lab data, scales, etc. The limitations of different DBMS programs in accommodating different file structures will be discussed below.

With a structure established for the database and definitions set for acceptable data elements, the process of data entry can begin. This is one area in which the computer's abilities enhance studies by promoting the capture of accurate data. As the user enters each value, the microprocessor can compare it with its respective data definition in form and content. In the event of an inconsistency, the computer prompts the user to correct the mistake. Only then will it store the new value in the patient's record.

An important feature of many DBMS programs is the ability to accept and store data from other programs (e.g., computer-administered psychometric tests), biofeedback instruments, and other computers. To do this, a DBMS program needs a function which accepts a stream of data in the same format as the output of the initial program. The standardized ASCII code is the most common format for sending a stream of data from one computer to another or one program to another within the same computer.

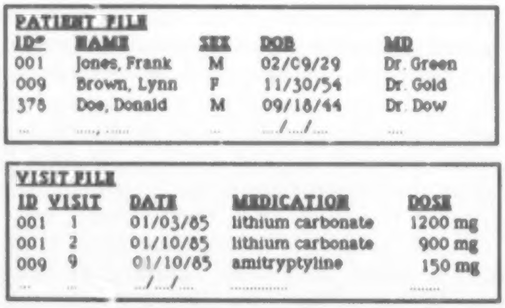
Data retrieval is the *raison d'etre* for database management systems. At its simplest, retrieval can be used to print a copy of each patient's record. Since DBMSs can reorganize data with relative independence from any physical layout, it is possible to do a more complex and very useful function called *searching*. Searching can be used to gather just the improvement scores from all patients' records, or to compile the data into a particular format for statistical analysis. Once initial data have been entered, searching can be used to review an entire file of records for missing data, prompting the user to complete the data entry process, and to allow editing of stored data which, although consistent in form and content, are still incorrect.

The ability to electronically rearrange or *sort* the order of data can also save considerable labor and time. In the example study 100 subjects are treated with lithium for 10 weeks and data are gathered from the history, mental status, lab tests, vital signs, and rating scales. Each data element is coded numerically and entered each week as it is obtained. At the conclusion of the trial we rearrange the order of the data set from the simple chronologic form in which it was gathered to the order needed for the analysis. In this final form, the patients are listed according to who entered the study first, then second, etc. After each subject is listed, then their baseline data is listed, then week 1 data, then week 2, etc. When subject 1's data are fully listed, then subject 2's follows. Sorting can be performed in different ways upon any data element in a record, such as chronologically by age of subject or date of visit, alphabetically by name of subject or clinician, or ordinally by lowest dose to highest.

Querying is a retrieval function which produces a more specialized search of the data, linking values from different data elements. An example of a query would be: "list all subjects with lithium levels greater than 1.2 who had global improvement scores of>3 for 2 or more consecutive weeks." Another important function of retrieval is the ability to extract data from the database to perform statistics or to graph. Few DBMSs are programmed to perform a full range of statistical tests, so additional software is usually required to do this (Crouch, 1985). However, if a·database can report its retrieved data in the same data transfer format as that accepted by the statistical package, time can be greatly reduced and errors can be eliminated by making an electronic transfer of the data.

Forms of File Organization (King et al., 1983)

The simplest microcomputer programs for constructing a database are called *file management systems.* These have a structure like a vertical list, making these programs easiest to learn for the new user. The variables of the list can be sorted in different ways to create different reports, but each list is separate. It is often useful or necessary (because of the finite capacities of a DBMS program) to use more than one file to store different types of data—demographic data might go into the "Patient" file, while treatment data might go into a "Visits" file. Figure 2 depicts a file management system with two different files (here in the format of tables), with no relation between the data in the patient file and the visit file. Each of these is just a two-dimensional file structure. Being able to store these data but not to be able to keep the two sets of files linked, is a ridiculous limitation. A better file organization is needed, necessitating a more flexible program that allows us to symbolically relate each patient in the first list to their respective visits and medications in the second list, and so on. This type of program is called a *relational database management system* (Figure 3).



PATIENT FILE

ID#	NAME	SEX	DOB	MD
001	Jones, Frank	M	02/09/29	Dr. Green

001	2	01/10/85	lithium carbonate	900 mg
...	...	.../.../...	....	....

ID#	LAB TEST	DATE	RESULT
001	serum lithium	01/05/85	1.0 meq/l
001	serum lithium	01/09/85	1.3 meq/l
...	....	.../.../...	.....

FIGURE 3. Relational database. The arrows indicate that relations can be drawn between data fields in different files, creating a three-dimensional file structure.

The relational database program is able to create relationships between data fields in different files, either right from the beginning or long after the initial format was laid out and even after much data has been stored in the system. A relational database management system allows users to create relations between data organized in different lists, e.g., as represented by the arrows. So while a file management system is like a two-dimensional list, a relational database is three-dimensional or more.

There is another form of organization that is multi-dimensional, and allows different files to relate to one another: the *hierarchical DBMS.* In hierarchical files, data elements are organized in several levels, structured one below another, like an inverted tree (Figure 4). This structure is set out from the beginning, however, and can't be changed once data are entered—the structure is fixed. This might seem a limitation, but is really an advantage for clinical researchers. The database for any given study should usually be laid out from the outset anyway, and a hierachical structure is easier to set up and to comprehend later. It also makes the data easier to search later. Finally, for clinical data, it is usually important that *one particular relationship be fixed: time.* Since we treat our patients over time, and they respond over time, any particular lab test or therapeutic intervention should always be forced to relate to time first, and to anything else second. DBMSs that fix certain relationships are called *hierarchical DBMS*s. When a hierarchical DBMS is designed to *fix the relationship of all items with respect to time,* it is called a *time-oriented DBMS*. A time-oriented DBMS is essential for building a clinical database.

Actual Use of Database Management Systems on Microcomputers

Some DBMSs let you select a task from a list of the possible alternatives, or *menu*; others require one to remember or look up a set of command codes. For the nonexpert user, *menu-driven* programs are much easier, because there is no need to memorize the options and less likelihood of forgetting how the program operates. The most popular DBMS in the world, dBase II, is only command-driven, but most of the newer programs offer a choice. DBase III, MetaFile, R:base 5000, and File Manager, allow the user to work from either menus or commands (Gresehover, 1984).

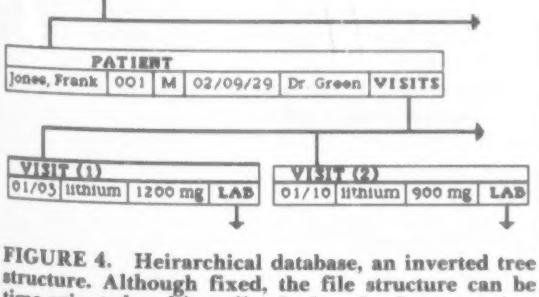

FIGURE 4. Heirarchical database, an inverted tree structure. Although fixed, the file structure can be time-oriented and is well suited to the data organization of clinical trials.

Some DBMSs have extensive statistical and graphics functions built in. These are called integrated DBMSs and their retrieval facilities include the transfer of data from the database subprogram to the statistical or graphics subprogram. Integrated DBMSs are time-saving because one doesn't have to rekey data from the database program to the statistical or graphics package. On the other hand, in the commercial software market, many integrated programs operate like a Swiss army knife—jack of all trades, master of none. While Lotus 1-2-3 might not meet the database needs of a research study, others such as Medlog (Layard, 1983) and Clinical Research System II (Crouch, 1985) are specifically designed for clinical trials.

In trials where more than one user will need to access records at one time, a multiuser DBMS is required. There are a growing number of general purpose microcomputer multi-user DBMSs on the market as well as some specifically developed for managing medical information, such as COSTAR (Barnett, 1984) and VA File Manager (Houser, 1984). These programs include additional features to protect information in the database from the vicissitudes of having multiple and simultaneous users. Two of these features are file lockout and security identification codes.

The following example demonstrates the need for *file lockout*: If a patient's chart folder is removed from the file drawer and then a lab slip is absent-mindedly dropped into the proper location, the slip falls to the bottom of the file drawer, forever misplaced. This mechanism of data loss can be prevented in a computerized database with file lockout. If a research assistant accesses a subject's file to enter a serum level while the researcher tries to update his assessment of the same subject, the system first updates the serum level, momentarily "locking" the file and holding the investigator's assessment entry. Once the level has been electronically updated, the investigator's entry is then recorded.

Security identification codes can be assigned for different levels of users, in the form of passwords. A secretary's password may gain access to demographic and schedule data (but not clinical), a clinician's may gain access to his own patients' clinical data (but hides placebo/drug status fields), and the principal investigator's password yields access to the aggregate.

Finally, the Veterans Administration File Manager program is worthy of special mention because it is a multi-user, hierarchical database (time oriented) and is designed to be a "programmerless system," allowing the user to set up his own complex flexible clinical database without extensive technical knowledge or time investment (Gastfriend et al., 1984).

Summary

With their increasing power and decreasing costs, microcomputers are proving a valuable tool for clinical research data management. A wide variety of database management systems is commercially available, offering differing levels of ease of use and capabilities (Bond, 1984). In selecting the best software program, the researcher must consider what types of data elements will be stored and must make an approximate calculation of total data storage needs. The three basic forms of file organization are: 1) file management systems; 2) relational DBMSs; and 3) hierarchical DBMSs. File management systems are easiest to learn but are too limited for most studies. Relational DBMSs allow free rearrangement of complex relations between different files, but these relations can become very abstract and learning to use them can be as difficult as learning a new programming language. Hierarchical DBMSs are more powerful than file management systems and are more understandable than relational DBMSs. For novice or casual users, menu-driven programs are more easily learned and used, but those accessing computerized files on a daily basis will appreciate newer programs that allow switching from menu mode to command mode of operation. Finally, options such as data transfer into the database or out of it, integration of statistical or graphics functions designed for clinical research, and multi-user operation are becoming available in microcomputer DMBS software and enhanced productivity as well as accuracy.

SAFTEE: Data System for Side Effect Assessment Scale

Dean J. Clyde, Ph.D.[1]

The National Institute of Mental Health (NIMH) has developed a method for assessing side effects of drugs. The assessments are recorded on case report forms called Systematic Assessment for Treatment-Emergent Events (SAFTEE) (Levine & Schooler, 1984).

Clyde Computing Service[1] received a grant from the NIMH under the Public Health Service Small Business Innovation Research Program to develop software for handling SAFTEE data on microcomputers. Because of the variable length records resulting from data collection via the SAFTEE form, a specialized data entry system was required.

Most data collection instruments or case report forms used in clinical trials have a fixed number of questions generating the same fixed number of variables for each patient. For this type of data, software for the data entry (and verification) into microcomputers is widely available. The Clyde Statistical Analysis System (Clyde, 1984) for IBM Personal Computers is one available software system. However, SAFTEE forms permit a varying number of questions and answers for each patient. A number of specific adverse health events are printed on the forms and the clinician may also write in additional events that the patient reports. This results in data records of variable lengths.

The SAFTEE system software is written for use on the IBM Personal Computer. The program allows for data entry and data summarization as well as transfer to other software systems or database management packages. Use of other database software is the most efficient way to handle the statistical analysis of these data.

The microcomputer package R:base 5000 (Microrim, 1985) was selected from approximately 75 such available packages because of its power and capacity to accept variable length records. In order to save disk space on the microcomputer, the data generated by SAFTEE are compressed into one bit per data item before being transfered into R:base 5000 (which tries to store data in 32 bits per item).

Investigators who collect SAFTEE data in clinical trials can either obtain the programs from Clyde Computing Service and do their own data entry or make arrangements to send the forms to the Clyde Computing Service for entry and analyses.

Microprocessor-Based Assessment of Attention Deficit Disorders (ADD)

Michael Gordon, Ph.D.[1]

Dissatisfaction with formulating a diagnosis of ADD with hyperactivity (ADD-H) based almost entirely upon clinical judgment or the perception of raters has spawned the development of behavior-based assessment procedures. These efforts typically involve administration of the Continuous Performance Test (Rosvold et al., 1956) or related measures of attention and self-control (Davenport, 1972; Doyle et al., 1976; Hiscock et al., 1979; Margolis, 1972). Although bulky and expensive electromechanical devices had previously been required, researchers are now programming microcomputers to administer these laboratory tasks to children (Conners, 1980; Klee & Garfinkel, 1983).

Use of the microcomputer has certain advantages, including flexibility of administration, the ability to store multiple data points, and, if a microcomputer is already available, cost-effectiveness. This approach, however, does have drawbacks for the researcher and, in particular, the clinician. The size of even portable microcomputers can make testing in multiple sites cumbersome. It is perhaps for this reason that standardization samples for software-driven programs tend to be, at best, limited in number and breadth. The transport of disk drives, monitors, keyboards, and the computer itself from location to location often discourages use of the procedure in other than a single research or clinic setting.

Another potential limitation of microcomputer-based testing stems from concerns surrounding the reliability of administration. Computer monitors vary in the size, shape, intensity, and color of displayed characters. Each brand of computer presents to the child a different keyboard, and accepts different types of peripherals, such as "joysticks," which are often used as manipulanda. Without control over such critical factors as the amount of pressure necessary to actuate a switch, or the accuracy of timed sequences, repeatable administration across multiple microcomputers cannot be assured.

Finally, ADD-H children, despite a reputation for academic underachievement, routinely display a fine facility for disassembling delicate equipment. Unless the examiner is immediately present, the highly impulsive child will inevitably stick a finger in disk drives, unplug cables, adjust monitors, or in some other fashion interrupt standard administration of the task. Efforts to secure the microcomputer are often unsatisfactory because they usually involve additional hardware, cabling, and expense.

An alternative approach to testing attention and self-control has been developed by the author (Gordon & McClure, 1983, 1984). The goal of this project has been to establish a practical, reliable, and well-standardized procedure available to both researchers and clinicians. The Gordon Diagnostic System (GDS) is a microprocessor-based, portable unit which, without an external microcomputer, allows for the administration of multiple tasks. The Delay Task, based upon a DRL operant schedule, requires the child to inhibit responding in order to gain a reward. Specifically, the child is instructed to press a button, wait, and then press the button again. If she or he refrains from responding for at least 6 seconds, a light flashes and a reward counter increments. If the child responds before the interval elapses, then the timer resets and no reward points are recorded. The GDS Delay Task generates three major scores: the number of responses (button presses), the number of correct responses (i.e., Correct), and the Efficiency Ratio, which represents the percentage of correct responses.

The GDS also contains the Vigilance Task, which is a version of the Continuous Performance Test (Rosvold et al., 1956). The child is presented with a series of digits on the front display and is told to press the button every time a "9" appears that had been preceded by a "1." The GDS records the number of correct presses, the number of times the child fails to press the button when the "1/9" combination appears (i.e., errors of omission), and the number of extraneous button presses (i.e., errors of commission). For the testing of younger children, the GDS contains a "1" mode, which requires the subject to press the button every time a "1" appears. The same performance measures are recorded.

---

[1] SUNY-Upstate Medical Center, Syracuse, NY 13210.

Although normative data were gathered using standard settings for task parameters, the design allows the user to select a wide range of parameters. This feature enabled the modification of parameters for the testing of adults as well as very young children.

Because the GDS is controlled by a programmable microprocessor, additional tasks can be explored. One such enhancement being studied is a version of the Vigilance Task which assesses the impact of distraction on a child's ability to sustain attention. This Distractibility Task is identical to the standard Vigilance Task except that random digits flash at random intervals on the outer positions of the LED display. The subject is still required to press the blue button when a "9" comes right after a "1." The only difference is that numbers flash on either side of the center (i.e., relevant) digit. Other enhancements under development are designed to evaluate attention across sensory modalities.

Even though the GDS administers tasks independently of a microcomputer, it can communicate with external hardware via an RS232C communications port. Software is available which allows for the direct transmission of GDS data to a microcomputer where it can be tabulated, graphed, stored, and compared to normative data. Connection of the GDS to a microcomputer enables collection of some ancillary data which cannot be extracted from the stand-alone unit.

The portability and ease-of-operation of the GDS has allowed for large-scale data collection. The standardization sample is composed of 1,100 boys and girls from 3 to 16 years of age (Gordon & Mettelman, 1985). An additional 1,100 hyperactive and nonhyperactive protocols from various subject populations, including the deaf, blind, Spanish-speaking, emotionally disturbed, and learning disabled, have also been gathered.

A series of validational studies has shown that these game-like tasks differentiated accurately between hyperactive and nonhyperactive children from both outpatient and day treatment settings (Gordon, 1979; McClure & Gordon, 1984). In a sample of school-referred children, the GDS distinguished children with ADD from those classified as reading disabled, overanxious, and normal (Gordon & McClure, 1983). Over 20 university and medical center research sites are currently conducting investigations involving the GDS. Most studies concern the effectiveness of the GDS for determining drug responsivity and for evaluating the success of pharmacotherapy (Atkinson, 1985; Barkley, 1985; Rapport, 1985). Others are investigating the use of the GDS for evaluating children with known brain damage, preschoolers considered "at-risk" for impulsive behavior, and the relationship between GDS scores and observational measures of classroom behavior. The GDS is also being used by school systems and pediatric practices across the country for the clinical evaluation of ADD-H.

Comments and Conclusions

A chronic impediment in the field of ADD-H has been the paucity of universal criteria and procedures for subject selection and treatment monitoring. Even in the realm of behavioral assessment, where truly creative approaches to testing children have been developed, procedures have generally not been sufficiently practical or well-standardized to allow for acceptance by the majority of professionals (Loney, 1981). As such, most continue to rely on rating scales or tests, such as the Wechsler Intelligence Scale for Children (WISC-R) (Wechsler, 1974), which have been shown to be of limited usefulness in differentiating between groups (Douglas, 1972). Furthermore, comparison of studies across research programs has often been hampered by idiosyncratic measures or sets of criteria.

The GDS represents an effort to establish a standard procedure for evaluating certain aspects of attention and self-control. While it is more costly and, in certain respects, less flexible than software-driven approaches, its portability, ruggedness, and extensive base of normative data offer the user greater assurance of reliable administration and valid interpretation. The growing acceptance of the GDS within the professional community also permits greater comparison of data across studies.

It must be emphasized, however, that the GDS was never intended as a divining rod for ADD-H. This is a complex disorder which represents an array of subgroups and interactive diagnostic dimensions. The GDS is seen as an important tool to be used only in conjunction with other selection criteria and clinical judgment.

A Microcomputer-Based Psychophysiology Data Acquisition and Analysis System

C. Keith Conners, Ph.D.,[1,2] Roy Clymer, Ph.D.,[1] and Robert S. Sherrick, Ph.D.[1]

The recording of autonomic and electrophysiologic signals from patients under different conditions of drug treatment, cognitive tasks, or emotional states can provide an important source of information in clinical research settings. However, the considerable costs of the laboratory equipment, the degree of technical expertise required, and the labor-intensive requirements of analysis and display of information are all factors which have limited the application of psychophysiologic techniques to a relatively few dedicated laboratories. The advent of the microcomputer, however, promises to make these methods more widely available to psychopharmacologists and clinician-researchers.

In this article we describe a comprehensive, general purpose Apple computer-based psychophysiologic data analysis and acquisition system which was developed in the course of drug and nutrition studies with children. The software system is flexibly designed to allow for creation of a variety of testing paradigms which might require the simultaneous acquisition of data from several physiologic channels during active subject problem-solving and performance testing. The system allows for a comprehensive assessment of behavioral, cognitive, electrocortical, and autonomic variables, which has proven to be valuable in drug studies where it is desirable to examine the impact of a drug upon multiple response systems at different dosages and over different time periods. The system is menu-driven and easily learned by nontechnically oriented users.

Hardware

The most expensive part of a psychophysiologic system is the human operator, who, in addition to the time spent actually acquiring data, must usually spend many hours in the scoring and reduction of the vast quantities of data obtained during test sessions. The Apple II+ or Apple IIe, because of its remarkably low cost and flexibility, is a powerful tool for addressing this aspect of the psychophysiology problem.

After the operator, the most significant costs are usually associated with the equipment required to detect and transduce the physiologic signals into electrical energy which can be analyzed for its frequency and amplitude characteristics in relation to experimental parameters. Many companies now manufacture suitable and relatively inexpensive modular components for signal acquisition and transduction which obviates the need for expensive polygraphic equipment.* These components are designed for different physiologic signal characteristics and typically will amplify, shape, filter, integrate, or compare the analog physiologic signals which can then be used for further analysis.

Once acquired, such signals must be converted from their continuous (analog) voltage form into a numeric (digital) form suitable for further analysis. Analog-to-digital (A/D) conversion of input signals is greatly facilitated by an interface which utilizes pre-defined machine language routines which require only a simple BASIC-like higher-order interpretive computer language. This general re-

*A high-quality, inexpensive source for modular signal processing equipment which we have used is Med Associates, Box 47, East Fairfield, VT 05448.

quirement can best be met by dedicated hardware which flexibly acquires many channels of information simultaneously, including binary (off-on) information such as button pushes or movement events: and which provides the timing and display requirements ordinarily available only on expensive polygraphs. We have used the Cyborg ISAAC Model 91a* for this purpose. The ISAAC™ system (Integrated System for Automated Acquisition and Control) includes 16 input channels for A/D conversion, and 16 binary input channels. It also contains computer-controllable binary and analog outputs which can be used to control an experiment, including four D/A and 16 binary outputs. The system also has four Schmitt Trigger inputs, a counter, and on-board 32-bit clock. All of these functions may be easily controlled by a high-level BASIC-like language, LABSOFT™ which consists of simple statements which can be added to Applesoft programs. Analog signals are processed as IRIG signals (1.4 volts full scale), a format compatible with most popular polygraphs, and FM tape recorders. Digital signals use standard 5-volt TTL logic.

Although the LABSOFT program is simple and fairly powerful, it has two important limitations which restrict its utility: 1) It does not allow easily for multiple functions to be performed in real time at once (e.g., taking A/D samples while monitoring for subject button presses). The LABSOFT program is fast when doing only a single task. For example, it can take A/D samples at 1,000 samples per second. When faced with performing multiple tasks simultaneously, however, it is considerably slower. A typical psychophysiological application might require measuring several channels of electroencephalograph (EEG), electrocardiograph (ECG) R-wave timing, subject button-press responses, activity level, and subject respirations all at the same time. Multiple functions can only be performed at a great sacrifice in speed. 2) LABSOFT is large, and allows only 4K bytes of computer memory for data storage in a 64K Apple if both high-resolution graphics pages of the Apple are being used for data display of incoming analog information.

Software

In order to circumvent the speed and memory size problems, a machine language software package called ISIINT was developed that requires only 2K of memory and can perform up to 14 functions simultaneously. ISIINT is like LABSOFT in that it consists of utility routines that can be called from Applesoft Basic programs. Applesoft integer arrays are used for passing parameters and data between the Applesoft Basic program and the ISIINT utilities. ISIINT uses one of the ISAAC timing elements to generate a real time clock that can be started and stopped under program control. Clock interrupts or "tics" can be set in software to occur as often as 1 per millisecond (msec) or as seldom as once every 65 seconds.

Through the use of the ISIINT utilities, any type of input or output that the ISAAC hardware is capable of performing can be scheduled to occur at a specified clock interrupt. For example, an A/D operation can be scheduled to occur at the 500th clock tic via a call to the ISIINT utilities. With another call to ISIINT, the clock can be started with a clock tic spacing of 10 msec. The A/D operation will then occur exactly 5 seconds after the clock is started without further interven-

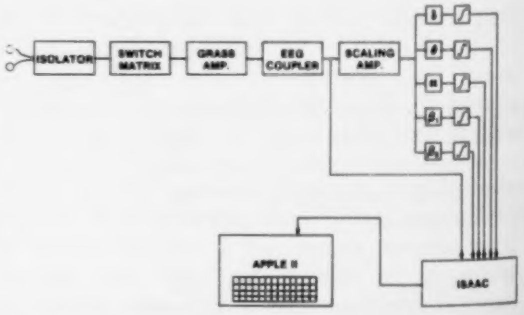

FIGURE 1. EEG/Evoked potential data collection system. Data from the subject electrodes passes through an optical isolator (required for subject protection), to a Grass EEG amplifier. The analog signal is then digitized by ISAAC and *stored in an* Apple array for EP measurement. The same signal is passed through sharp Butterworth bandpass filters for measurement of relative power in each of 5 frequency bands.

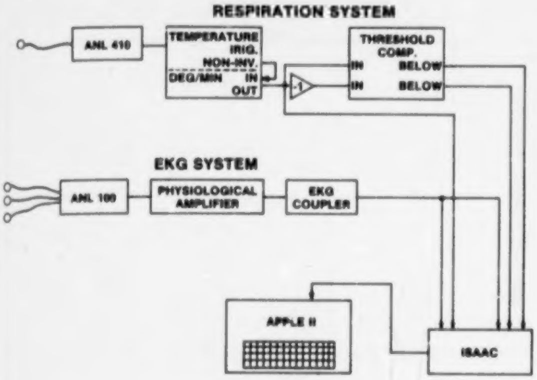

FIGURE 2. Respiration and heart rate data collection system. A thermistor attached to the nostril provides a temperature signal which changes with inspiration/expiration. The thermistor signal is amplified and transduced by a Med Associates ANL 410 module and converted to a value representing inspiration or expiration by a threshold comparator. The R-wave of the ECG (collected from the Med Associates ANL 100 module) is amplified and converted to a binary pulse used to activate an ISAAC Schmitt Trigger. The ISAAC and ISIINT routines are used to calculate interbeat intervals. The Apple-II+ can display the analog information in real time on the high-resolution screen during data collection.

tion by the Applesoft program. All ISIINT input/output operations occur in the "background" while an Applesoft Basic program is running in the "foreground." When many background input/output operations are scheduled, the foreground Basic program runs more slowly than normal, but it is not otherwise affected. When data become available via background input operations, they are placed into Basic integer arrays.

In addition to allowing all possible ISAAC input/output operations and real-time clock control, ISIINT also allows the user to schedule PEEK and POKE operations, read the clock, read background operation status information, and perform several useful functions not associated with the real time clock, such as adding two Basic integer arrays in a fraction of the time required by a similar routine in Applesoft Basic (this latter capability permits immediate display of averaged EEG-evoked potential data). Since all utility functions are accessed via Applesoft Basic "Call" operations, ISIINT is simple to use and does not require a knowledge of assembly language or a detailed understanding of the ISAAC hardware. Parameters and data are passed via integer arrays. Upon receiving a call, ISIINT may either perform a function immediately (such as clearing the counter, starting or stopping the clock), schedule a function, stop an already scheduled function, or enter a value (such as the time). The action taken by ISIINT depends upon the values passed to it in the parameter array.

Sample Application

A description of a study recently conducted using the Apple/ISAAC/ISIINT system may serve to demonstrate its capabilities. An experiment was conducted to ascertain the behavioral and physiological effects of a drug and a placebo given in two dosage regimens. In the single-dose condition a large dose of the investigational drug was given in the beginning of the experiment. In the distributed-dose condition the same quantity of drug was given, but in four equal doses 1 hour apart. In order to make the experiment double-blind, all dosages were matched for volume. Thus, in the distributed-dose condition the volume of the first drink, although containing one quarter of the drug, was equal to the first drink in the single-dose condition due to the addition of an appropriate quantity of placebo. Similarly, three placebo doses were given in the single-dose condition to match the quarter-doses given in the distributed dose condition. Subjects were 8- to 12-year-old normal children. It was desired to collect information on attentional set through the cardiac deceleration to a warned reaction-time task; on cortical alertness through quantitative EEG and visual evoked response; on behavioral attentiveness through a continuous performance task (CPT); on respiration rate associated with attention deployment; and on general activity obtained from counters attached to a stabilimiter in the subject's chair.

The primary performance measure was a "letter-form" version of the CPT. In this task the subject is required to press a response key whenever two letters appear in sequence from a series which includes both letters and letter-like forms matched for area (and consequently for brightness). This task, although an interesting measure of attending in itself,

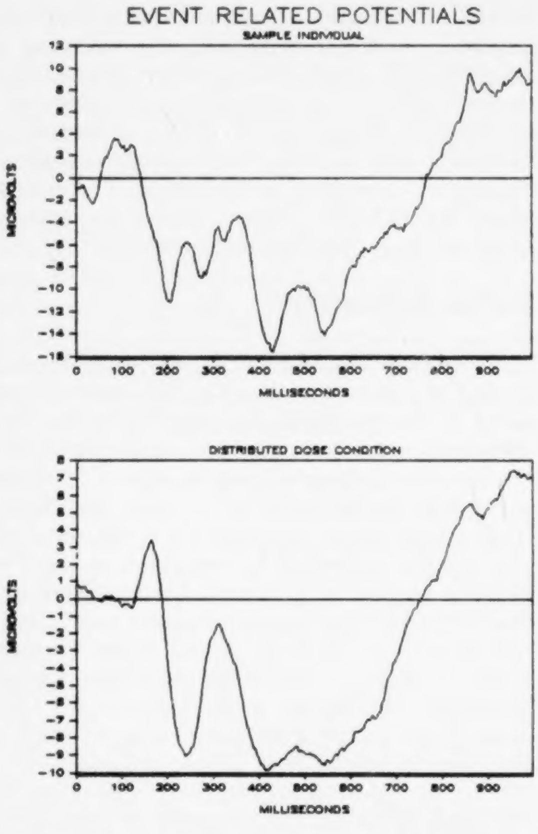

FIGURE 3. Individual and group-evoked potentials collected with ISIINT.

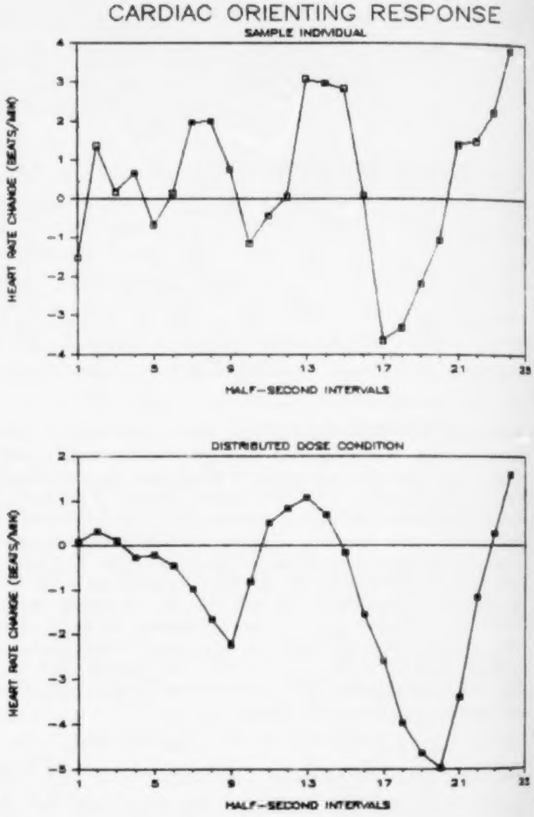

FIGURE 4. Individual and group cardiac changes during a 6-second warned reaction-time task.

has the added advantage of allowing the simultaneous gathering of averaged visual evoked potentials generated from both letter and form-stimuli, making it possible to ask interesting questions regarding hemisphere-specific processing. Figure 1 is a diagram of the hardware system used to gather EEG data.

A single input electrode (Cz referred to linked mastoids) was used to gather both ERP data and frequency band data. During the CPT task the Apple/ISAAC/ISIINT system was used to gather and average the EEG waveforms for 1,000 msecs following each visual stimulus presented on the monitor. The ISIINT program provided two averaged waveforms, one for the correct rejections and one for hits.

The CPT task also provided four performance measures: number of hits, number of correct rejections (targets which did not require and did not elicit a response by S), number of errors of commission (key presses to stimuli which were not the target), and the average reaction time to press the key after a target. Thus, a single task allowed monitoring of a variety of behavioral and psychophysiological variables.

A second task which also sampled two measurement levels was a warned reaction time task (Simons et al., 1979). The R-wave from a standard Lead II ECG activated one of the Schmitt trigger inputs of the ISSAC. The interbeat interval was recorded and converted to a rate per 1/2 second interval (Gatchel & Lang, 1973). A series of 20 reaction time trials was presented, with sampling beginning 3 seconds prior to the onset of a 6-second warning tone. The subject pressed a response

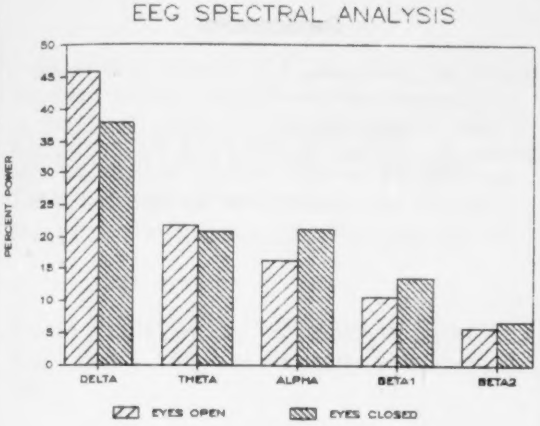

FIGURE 5. Changes in relative EEG power with eyes open and eyes closed.

key when a circle appeared on the monitor at the end of the warning tone. The heart rate was expressed as a deviation from the prestimulus average heart rate and an averaged evoked cardiac response was obtained by averaging across the 20 trials (Simons et al., 1979). In addition, the cardiac-orienting task yielded measures of misses, errors of commission, and warned reaction time. An automatic detection and correction routine removed artifacts created by movement.

Sixty-second samples of three additional psychophysiological measures were obtained periodically throughout the experiment. Respiration rate was obtained from a nasal thermistor taped near the nostril and peak change in temperature was used to identify respiratory influxes. Heart rate was obtained from the same Lead II ECG used in the warned reaction time task. Finally, the EEG from the Cz electrode was fed to a series of filters and integrators from the modular input equipment which provided on-line measurements of the relative proportion of power in each of the five EEG frequency bands (theta, delta, alpha, beta1, and beta2). Note that this "hardware" function could be easily obtained by software programmed to achieve the same goal. Each of these measures was sampled for 30 seconds with S's eyes open and then 30 seconds with their eyes closed. Figure 2 is a block diagram of the components used to obtain these measures.

Results

Since the purpose of this article is a description of the Apple/ISAAC/ISIINT system, the results of this experiment will be discussed only insofar as they are illustrative of the data gathering capabilities of the system.

Figure 3 displays some of the averaged evoked response data. The top panel is the ERP of a single subject, averaged across 88 correct hits. The bottom panel shows the evoked response to hits averaged across 20 subjects in the single-dose condition. The individual peak amplitudes and latencies were hand scored by a program which displays the EPs on the Apple high-resolution screen and allows the use of an adjustable cursor which reads out the time and amplitude of the wave wherever it is positioned. Subsequent statistical analyses may then be performed upon appropriate peaks.

Typical evoked cardiac response data are shown in Figure 4. Again the upper panel shows the data from a representative subject, while the lower panel shows the data averaged across all subjects. The data show the expected tri-phasic response (Gatchel & Lang, 1973).

In Figure 5 some of the EEG frequency band data is presented. The EEG was taken for 30 seconds with eyes open, then the eyes were closed and a minute later 30 seconds of EEG with eyes closed was taken. The data show the increase in alpha and expected shift to lower frequencies with eyes closed. (Not shown here are the sequential activity counts which were collected throughout the subject-day, or the respiration data.)

Conclusion

Most laboratories interested in psychophysiological recording will have access to the appropriate signal collection input modules, but the most difficult and expensive task is the computer storage, analysis, and display of the data. Typically, this has required mini-computers which are both expensive and difficult for the non-programmer to use. The system described here allows a comprehensive and sophisticated behavioral, electrophysiologic, and psychophysiologic experiment that is flexible and easy to use. Data are immediately displayed and graphed without long delay between the experiment and subsequent data reduction. The cost of this system compared to others may recommend it as a valuable experimental tool.

A Brain Function Diagnostic and Study Unit for Psychotropic Drug Development and Psychopharmacology Research

Turan M. Itil, M.D.,[1,3] Donald M. Shapiro,[2] Emin Eralp,[3] Ahmet Akman,[3] and Kurt Z. Itil[3]

Quantified electroencephalogram (EEG), evoked potential (EP), and neuropsychological tests have been proven to be reliable objective tests to study the effects of drugs on human brain function. In particular, when analyzed by digital computer, EEG can provide information about the minimum effective dose of a drug on the central nervous system (CNS), the onset and duration of CNS effects, and the mode of action of psychotropic drugs (Dolce & Kunkel, 1974; Fink, 1969; Itil, 1974). Recent investigations indicate that computer-analyzed EEG (CEEG™) can determine the type of psychotropic properties of the compound, its potency, and therapeutic window (Fink, 1974; Herrman, 1982; Itil et al., 1979). CEEG has also been applied successfully to determine the bioavailability and bioequivalency of psychotropic drugs and predicted therapeutic outcome in individual patients (Fink, 1974; Itil, 1974, 1977; Itil & Krynicki, 1983).

This paper summarizes a new system called the Brain Function Diagnostic Unit (BFDU™) (Itil et al., 1985) which provides information on brain function and its changes due to drug effects based on Quantitative Neurophysiological Testing results (EEG, EP, sleep), Interactive Neuropsychological and Psychometric tests, and integrative medical and neuropsychiatric summary data.

Quantitative Neurophysiological Testing

Computer EEG data collection and analysis system: The electrical phenomena of the brain, collected through a newly developed electrode helmet, are amplified via standard EEG machine amplifiers. The activity is recorded on a standard EEG strip chart by a conventional EEG writing system. (In the case of research, where the standard EEG strip chart may not be required, sensitive preamplifiers and laser printers may be used instead of the standard EEG machines.)

The same bioelectrical phenomena recorded on the strip chart are also first sent to the special 8-channel filter unit, then 8-channel analog-to-digital converter and, finally, to the microcomputer (IBM-PC/XT,AT or compatible). In addition to the EEG equipment and a microcomputer, some special peripheral hardware is required to conduct the EEG analysis with brain mapping:

a. Math Coprocessor
b. High Resolution Color Board
c. High Resolution Analog RGB Color Monitor
d. High-Speed Near Letter-Quality Printer

An extensive software package to conduct the following operations for these EEG data is also part of the BFDU:

1. A Clinical-Diagnostic EEG Program.

Provides quantitative outputs for each individual EEG lead, the frequency distribution of the mean of eight leads, and instant EEG reports with interpretation (unconfirmed). Simultaneously, colored hard copy topographic Dynamic Brain Map® are provided to help in the discrimination of abnormal or borderline records from normals.

2. Research EEG Programs.

For 8 to 16 channel power spectrum based on 6 to 22 variables and 8 to 16 channel period analysis (interval or zero-cross analysis) with 6 to 22 measurements.

[2] Computer Center, New York Medical College, Tarrytown, NY 10691.
[3] HZI Research Center, Tarrytown, NY 10691.

3 Statistical Packages Which Yield:

Drug-induced changes (pre- minus post-drug) based on univariate statistics.

Drug versus placebo discrimination based on univariate and multivariate statistics.

Individual and group CEEG drug profiles based on *t* profiles.

Drug classification based on HZI's CEEG database using correlation statistics.

Time- and dose-related CNS effects for group and individual subjects based on regression analysis.

Classification of individual subjects' response with the HZI database to determine psychotropic potency of a drug and to predict the therapeutic outcome.

Graphic packages of the statistical outputs and database classifications (hard copy).

Serial comparisons (predrug minus post-drug) by statistical means and by topographic colored brain maps.

Evoked Potential Data Collection and Analysis System

The major part of hardware for EP data collection analysis such as EEG machine, microcomputer (IBM-PC/XT or AT) and electrode headset are the same as used for the EEG data collection and analysis. The only additional hardware required are different types of stimulators (acoustic, visual, and tactile), built specially for our EP system.

Software specific to EP data includes, for example, standard (conventional) 8- to 16-channel analyses with hard copy; an instant clinical report (unconfirmed); colored dynamic topographic brain maps based on different types of EP; and an automatic artifacting system.

There are also some unconventional features, including: high signal-noise ratio; separate analysis of EP based on different EEG frequency patterns; selective averaging, etc.

Interactive Neuropsychological Test System

For the interactive neuropsychological and cognitive test batteries, in addition to the IBM-PC/XT or AT, a psychological test station is required. This station includes another microprocessor (Z-80), a specially developed monitor, light pen, and control panel.

New programs were developed in collaboration with the computer center of the Austrian Road Safety Board to conduct the following tests:

Non-verbal intelligence test, concentration test, simple choice reaction time test, long-term memory test, speed-distance estimation test, optical memory test, sensor-motor coordination test (tracking test), tapping test, and a list of questions on current physical and mental state.

The results of these tests are provided in three different formats:

1. A graphic format, which includes the summary of raw data and the comparison of the data with age-related norms.
2. Interpretation of each individual test result (unconfirmed).
3. A summary report on neuropsychological test results as required by the clinician (unconfirmed interpretation).

Integrative Clinical Report

A series of medical, neuropsychiatric questions are asked about the past history and present symptomatology of the patient. The answers suspected to be related to brain dysfunction of the patient will be integrated into a clinical-practical acceptable format. For the questions, either a rating scale is used, or the patient is given a lap computer which has an interactive approach. The lap computer is a Radio Shack Model 100 with 24K memory, built in RS-232 port, and modem. The integrative summary is provided in a clinically useful format.

Conclusions

BFDU has the following major advantages:

1. The BFDU has been developed on a building-block principle. One can start with a computer EEG system which includes a standard EEG machine (any 8- to 16-channel with IRIG output), an IBM personal microcomputer (XT or AT), and some peripheral hardware (printer, monitor, sine wave generator). If one requires the EP system, one needs to purchase only a stimulator and additional

software. For neuropsychological tests, one needs to purchase a neuropsychological test station and additional programs. With a simple lap computer and additional software, one completes the BFDU system.

2. All three major tests, EEG, EP, and Neuropsychological Tests, are done by standard equipment and the output are also standard. Software provides much additional information to the standards, including quantitative data, statistical results, and color topographic Dynamic Brain Maps which are useful both for psychopharmacology and clinical research.

3. The system is self-monitored by software for technical problems and/or artifacts so that no special manpower for the computer or other test is required.

4. BFDU provides instant clinical-diagnostic EEG reports to determine whether psychiatric patients or subjects included in psychopharmacology trials exhibit any abnormal brain functions; thus computer EEG can be used to screen subjects with "organicity" to exclude from the psychopharmacology studies.

5. BFDU can be used in every phase of psychotropic drug studies, but most significantly during Phase I trials (Itil et al., 1972, 1977, 1979, 1984). Using CEEG, the following important CNS *efficacy* information of a new compound is obtained during Phase I *safety* trials:

- To determine the *CNS effectiveness* of a compound based on CEEG changes between pre- and postdrug administration. All marketed psychotropic drugs produce statistically significant CEEG changes.
- To establish the "*bioavailability*" of a compound on the CNS based on pharmacodynamic changes. In addition to the typical pharmacokinetic measurements (e.g., t_{max}, c_{max}, and AUPDC), CEEG parameters can also be used for time and dose response curves.
- To classify the quality of the CNS effects of a compound, thus to *predict* the type of the *psychotropic properties* using HZI's CEEG database. It was established that drugs with similar CEEG profiles produce equivalent therapeutic effects. Based on CEEG profiles of four major psychotropic drug groups (CNS depressants–neuroleptics; mood elevators–antidepressants; anxiety relievers–anxiolytics–hypnotics; cognitive activators–psychostimulants) and CEEG "prints" of 840 subclasses of 139 CNS effective drugs, the computer can classify the type of psychotropic properties of a new compound.
- To predict the *therapeutic window* of a new compound. The doses of which CNS effects can statistically be discriminated from placebo and also can be classified by the computer database as psychotropic are also therapeutically effective.
- To *predict the potency* of the psychotropic properties of a new compound. According to the studies, the more potent a compound the more patients show "typical" CEEG effects (CEEG profiles) within 1 to 3 hours after a single dose oral administration. The more typical CNS effects are, the better classified is a compound by the computer database to a psychotropic drug group. Among the 139 CNS effective drugs, Valium^R, Elavil^R, and dextroamphetamine are the most homogeneous CNS effective compounds. If a new compound is administered to 12 healthy subjects and more than 75% of the subjects are classified with a typical response, this indicates that the studied compound shall have homogeneous effects on the CNS; thus it will be a potent psychotropic.
- Last, but not least, CEEG can be useful to demonstrate the CNS effects of drugs in individual subjects or a group of subjects after single or multiple doses. Thus, CEEG can be used to monitor CNS effects of psychotropic drugs. If there is no significant change in EEG also, no therapeutic effects can be expected in psychiatric patient populations.

BMDPC: BMDP Statistical Software for Microcomputers

MaryAnn Hill, Ph.D.[1]

In the fall of 1984, BMDP began distributing statistical software for IBM personal computers—the XT and AT, and compatibles such as the COMPAQ+. Since the BMDPC programs are the same as the BMDP mainframe programs, this development gives users the full power of a major, well-tested statistical package on a personal computer. The minimum requirements for a system to support BMDPC are a hard disk, an 8087 floating-point processor, 640 kilobytes of memory, and the capacity for double-sided, double-density floppy diskettes.

BMDPC is described in the following three sections: what is BMDP and how does it work, how does BMDPC differ from BMDP on the mainframe, and what is coming soon for BMDPC?

What Is BMDP and How Does It Work?

BMDP is a library of programs. Each program addresses a specific task or analysis: one program prints frequency tables and fits log linear models, another estimates a multiple linear regression equation, etc. BMDP provides a broad range of data description features and statistical analyses including *t* tests, analysis of variance (ANOVA) and covariance (ANCOVA) (repeated measures, multivariate ANOVA, mixed models), multiple regression (forward and backward stepping, all subsets, regression diagnostics), discriminant analysis, nonlinear regression, logistic regression, log linear models, cluster analysis, factor analysis, time series, and survival analysis including the Cox proportional hazards regression model. Most importantly, many procedures provide supports for the data analyst—graphical displays, diagnostics, and alternative tests that help the analyst estimate the degree to which assumptions (necessary for the analysis) are violated.

Each program uses the same basic set of instructions to describe the input data, name the variables, specify acceptable range limits and flags for missing data, select cases (old females from Clinic B in Boston), re-express data (change = baseline—week 4), and identify groups (male smokers, ... , female nonsmokers).

BMDP instructions are written in English sentences and are grouped into paragraphs. The most "basic set" of BMDP instructions (describing a data set containing pre- and post-exercise pulse measures) is shown in Figure 1. For many analyses, this basic set is all you need. For example, if these instructions were submitted to the factor analysis program, the output would contain a univariate data summary, a correlation matrix, eigenvalues associated with each factor, factor scores and Mahalanobis' distances for each case to the centroid of all cases, factor loadings with and without an orthogonal rotation, plots of loadings, and plots of factor scores. To limit the number of factors, or change the rotation type, the user adds instructions to the basic set.

Some programs require that paragraphs be added to the basic set. In Figure 2, a PLOT paragraph is added, requesting that the post-exercise pulse values be plotted against age in a bivariate scatterplot. The output, in addition to the scatterplot, includes the equation

```
/  INPUT            VARIABLES ARE 6.
                    FORMAT IS FREE.

/  VARIABLES        NAMES ARE ID, SEX, SMOKE,
                         AGE, PULSE_1, PULSE_2.

/  END
```

FIGURE 1. Basic BMDP instructions for data where each subject has an I.D., a code for sex and for smoking status, age, and pre and post exercise pulse values.

of the line of best fit (the location of this line is marked on the plot frame), the correlation (with tail probability), the residual mean square, and the means and standard deviations of pulse and age.

If, instead of a plot, the researcher wants a two-way table to test if the proportion of smokers is the same for males and females, the PLOT paragraph in Figure 2 is replaced by the TABLE paragraph in Figure 3.

A TRANSFORM paragraph, available in all programs, is useful for re-expressing data. All the usual arithmetic operators (multiplication, division, exponentiation) and functions (logs, square root, trigonometric) are available. Recently, for ease of data manipulation, more than 24 new transformation functions were added to the package. These functions produce results across variables on a record (e.g., SUM totals, say, 15 items on a record): other functions provide the mean, the minimum, the maximum, and the slope. Functions are also available to convert day-month-year dates to Julian form or to the number of days since January 1, 1960 (and vice versa).

How Does BMDPC Differ From BMDP on the Mainframe?

Researchers do not have to give up familiar mainframe options and features. Each BMDPC program (e.g., stepwise regression) has the *same* options, instructions, and documentation as its mainframe counterpart. But is the researcher handicapped with respect to size of problem and computational time? Yes, to problem size, if the analysis is on census data; no, for many of the studies in psychiatry, for which I am involved. Most BMDP programs do not require the data to be kept in memory—so problem size may be limited by the number of data items that can be stored on the hard disk. In Appendix B.2 of the *BMDP Statistical Software Manual, 1985 Reprinting*, formulas are given for the capacity of each particular analysis. For the standard mainframe installation, the maximum number "M" in these formulas is 15,000 (M is usually a function of the number of variables, number of groups, or number of cells in an ANOVA design). For BMDPC, the maximum value of "M" is 16,000. For example, if three megabytes are set aside on the hard disk for the data file, Program 1D could compute descriptive statistics for ten variables and 75,000 cases. More than 100 variables may be included in a stepwise regression run.

In sizable studies, millions of numbers may be collected when, say, for 200 subjects, many rating forms are administered repeatedly over time. Computing tasks for these studies may be distributed between the PC and the mainframe. For example, the data for each instrument could be cleaned separately on the micro at the center where they are collected, and later shipped or networked to a mainframe for merging with data from other centers. It should be pointed out that this distribution of computing also applies to the debugging of the BMDP instructions for analysis. The fine tuning of the instructions can be carried out on the micro for a subsample of the data and the instructions can then be shipped as text to the mainframe for final analysis of the complete file.

Of course, computation on the micro is slower than on the mainframe. However, the researcher is the only user on the micro, so the person sitting at a micro may not feel handicapped. On an IBM PC/XT, the time to execute the All Possible Subsets Regression searching algorithm for 23 variables is 45 seconds (by wrist watch). A factor analysis

```
/  TABLE         ROW IS SEX.
                 COLUMN IS SMOKE.
```

FIGURE 3. When a TABLE paragraph is added to the basic set of instructions the output contains a two-way frequency table plus the chi-square test of independence.

with 24 variables, including an orthogonal rotation, computation of factor scores, and other supplementary displays and supporting information, takes two minutes. Using the new BMDP Data Manager (described below), it took roughly 11 minutes by wrist watch to

—do *complex transformations* on each of 1,205 records in File A containing weekly clinic visits for 225 patients. For each record, transformation functions were used to check the number of missing values, sum 20 items, compare the total with another value, etc.

—use *aggregate functions* to generate 225, records with summary measures (i.e., one new record per patient summarizing his experience across weekly clinic visits).

—*join* this summary file *side-by-side* with File B, a 225-record demographic file, using the patient ID as a merge key.

In addition to the standard mainframe programs, BMDPC includes a line editor that allows the user to access both data and/or instruction files without leaving the program. With the new editor, the user loads the program once and makes a series of runs, inserting additional instructions or making corrections after each run, thus avoiding the delay of reloading the program after each error. The editor allows the user to get files from the system and to return modified files back to the system.

One difference between BMDPC and the mini and mainframe BMDP is the license procedure. Mainframe and mini-computer users lease the complete BMDP package for an annual fee—they have an annually renewable license. BMDPC users select a group or subset of the programs and pay a one-time-only fee—a perpetual license. Discounts are available for multiple copies of BMDPC leased to universities and research facilities.

What Is Coming Soon for BMDPC?

Each new release of BMDP includes modifications and enhancements. This year BMDP plans to introduce a new system: for managing data. This past year, BMDP began distributing the structural equations modeling program, EQS.

The Data Manager. An exciting new product to be released in 1985 is the data manager system that merges files, extracts summary information from sets of records that vary in number, and performs other file restructuring operations. In Figure 4, the procedures for merging files are illustrated. In Figure 4a, the subject ID is used as a key to merge records side-by-side from three files containing history, laboratory, and questionnaire data. In 4b, records from file B are

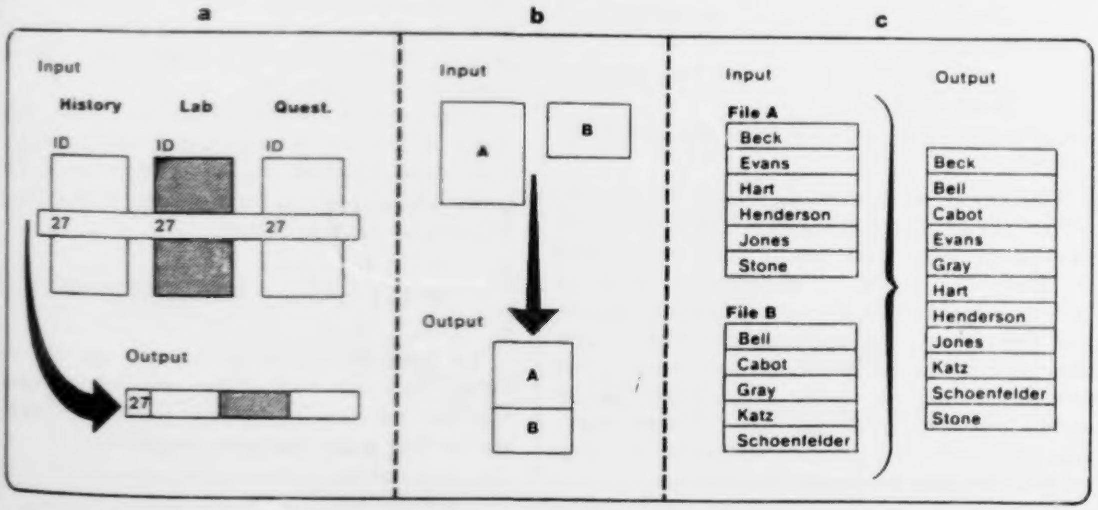

FIGURE 4. Merging files (a) side-by-side, (b) end-to-end, and (c) interleaving records.

Input

Family	Age	Income	Sex	Education
1	35	1500	1	12
1	33	1200	2	12
1	2	0	2	0
1	7	0	2	2
1	9	0	1	4
2	43	1800	2	16
2	39	1400	1	14
2	10	500	2	5

Output

Family	# in Family	Max. $	Total $	Max. $ Female	Education Max. $
1	5	1500	2700	1200	12
2	3	1800	3700	1800	16

FIGURE 5. Generating summary records.

added to the end of file A. In 4c, the subject's name is used to interleave records alphabetically from two input files. Output from more than two dozen summary functions can be 1) added to each input record, 2) used to generate summary records, or 3) added to records higher up in the hierarchy. For example, if a file contains records for individual family members with age, sex, education, monthly income, etc. (*see* Figure 5), you can use the summary functions to extract, for each family,

—the number of family members

—the total family income

—the maximum income for one member, the maximum for the males, the maximum for the females

—the education level of the member with the maximum income

—the sex of the member with maximum income

The development of measures to characterize social supports (social networks) of mental patients is an interesting illustration of how to extract information from a nonrectangular file. For each patient we collect one record for each person with whom the patient interacts. Thus, the number of records per patient varies. One patient has 18 in his network, while the next patient interacts with only two people. Variables on each member's record include the following:

—age, sex, frequency of contact, relationship to patient (relative, friend), etc.

—information about roles—the patient's interaction with each member (does he borrow money from the member, spend free time with him, etc.).

—a tally of the interaction with every member in the network (yes, Bill interacts with Jose; no, Bill does not interact with Sue, etc.).

The goal is to generate one record for each patient that summarizes the characteristics of his network: network size (the number of members), number of members interacting in at least one role, total number of roles experienced by the patient, the maximum number of interactions with one member, the member (e.g., mom) about whom the patient feels most negative and the contact score with this person, the number of "others" available for free-time activities, etc.

The generation of these summary measures is straightforward using the aggregate functions. To find the most negative feeling score among a patient's network members, we use the MIN function

MOST_NEG = MIN (FEELING).

To find who this person is, we use the FVAL function to find the value of the variable RELATION in the first record for which the feeling score was most negative.

WHO_NEG = FVAL (RELATION,
FEELING EQ MOST_NEG).

The ability to incorporate conditions in the summary functions also allows us to generate some measures using only the family records, other measures to summarize the nonfamily members. We did this for the number of family members and the number of others used in free time activities. Results were saved and plotted using the 9D miniplot options (*see* Figure 6). We grouped the patients by severity of illness (illness code 1 is severe, 4 is well) and ethnicity. The average number of friends is plotted on the vertical axis. A quick look at the plots provides a description of the results. Use of family members (F) for free time does not appear to be associated with severity of illness. However, use of "others" (O) does decrease markedly with illness, and the decrease is more dramatic for Anglos. The difference between family and "others" is smaller for the Hispanics—they appear to use more family members (probably because their families are larger).

Other data management supports are available to help produce the desired output file. You may *sort records* numerically and alphabetically; *select cases interactively*, e.g., male blue collar workers over 50 years of age who worked in an asbestos factory, *re-express data* using more than 30 functions and operators (LOG_WT = LOG (WEIGHT)), *convert dates* in day, month, and year form to Julian dates or days since January 1, 1960, report *univariate statistics* (n, $\bar{x}$, s, min, and max) for values of variables on input records or records created through file operations *print data* in user-specified fields or preassigned fields, etc. When limitations on computer funds make on-line data editing prohibitive, a batch edit capability is available also. Another feature the system provides is a *record map*—a

```

```

FIGURE 6. Number of family members (F) and others (O) available for free time activities (by illness and ethnicity).

graphical display in which each character represents the presence of a record.

The system was designed to handle the great majority of tasks encountered in research projects, while remaining reasonably easy to use. You should *not* require a programmer who is an expert in file structures in order to use it effectively. A data analyst can use the various data manipulation procedures interactively to learn both about the *structure of the records* (e.g., in a clinical trial, how many visits are missed for each patient? What is the pattern of return visits?) and the actual *data values* from cells defined by one or more grouping variables. For example, at 3 months, what is the change from baseline in clinical outcome scores for drug 1 completers (i.e., those subjects who remained on study 1 year), drug 1 dropouts, drug 2 completers, and so on.

Structural Equations Modeling Program. In 1985, BMDP began distribution of EQS (pronounced like the letter X), the structural equations modeling program developed by Professor Peter Bentler at UCLA. EQS permits distribution-free multivariate analyses, including multivariate regression, path analysis, simultaneous equation models, confirmatory factor analysis, latent variable models, etc. Structural equation models allow theory testing with nonexperimental data and for that reason are often called causal modeling methods. EQS is designed so that it requires no knowledge of matrix algebra. Models are specified using an equation language in the form

$$V1 = .5 * V2 + .8 * V3 + E1,$$

where variable V1 is regressed on variables V2 and V3, with error E1. The numbers preceding the asterisks are initial parameter estimates. In addition to parameter estimation using least squares, generalized least squares and maximum likelihood methods (based on elliptical theory) are available for nonnormal data. EQS is currently running on IBM and VAX computers as well as the IBM PC/XT and AT. Versions for other hardware will follow. Professor Bentler is widely published in the area of statistical methodology and is a past president of the Psychometric Society (1982–83).

Projects Under Development. As part of an NIMH research project at UCLA, a test program has been completed for repeated measures analysis of variance with incomplete data. W.J. Dixon is the principal investigator, and R. Jennrich and M. Schluchter are involved in design and programming for the project. In addition to handling incomplete data, the program allows a user-specified structure for the covariance parameters. This approach allows the data analyst to examine several different structures, each having important subject-matter interpretations.

Another program in design stage will allow the analysis of repeated measures categorical data, and at our office in Cork, Ireland, a program for correspondence analysis is under development.

How does BMDP decide what to include in the software? Suggestions come from several sources, including letters submitted by users. A panel of outside advisors meets twice a month to evaluate the suggestions. The panel includes members from the academic community and members actively involved in consulting in a variety of real world applications.

Communications: Microcomputer/ Mainframe Interfacing

Pierre Mercier, Ph.D.[1]

There are a number of practical and technical aspects related to the use of microcomputers in communication with mainframes. In a typical session such as exemplified below, the user logs-on to a mainframe computer using an asynchronous terminal emulator program and issues the necessary commands to transfer to data file to the microcomputer's storage device.

The basic technical aspects involved in performing this task include the essential hardware components, ASCII coding, serial interfacing (RS–232C), and modulation-demodulation. Trapping and correction of transmission errors must also be performed.

A Sample Application

In order to establish communications between a microcomputer and some remote machine, the user must first load a Terminal Emulator Program and set the necessary parameters. The data communication parameters will be explained in detail later; let us assume that default values are appropriate for now. Turning on the communications line, a TERMINAL READY message appears at the top of the screen. The IDENTIFICATION and PASSWORD statements are then required to access the mainframe. The exact order and syntax of these steps may vary from installation to installation but they are typical of the process.

The user is now on-line and can issue any command that the mainframe understands, or use any program that runs on it, with the associated processing power. On the other hand, it may be desirable to take the content of a data file which resides on the mainframe storage device, list its content on the screen, and record it on the microcomputer's disk drive at the same time. Within the restrictions imposed by the size of the destination device (typically in the range 120–320 Kilobytes for floppy drives or 5–20 Megabytes for hard disks on microcomputers versus 100–317 Megabytes for a mainframe disk pack), these data are then available for processing by the micro (e.g., using a statistical analysis program), thus saving on-line costs and generally offering a more interactive environment.

To execute the transfer, the data destination is first identified by creating a new file on the microcomputer's disk directory. Next, the terminal is put in RECORD mode and a DISPLAY command is sent to the remote. At this point, a listing of the file is obtained which is then automatically saved on the local disk. It is now possible to terminate the session (OFF), and replace the terminal emulator program with the application program needed to process the newly acquired data (e.g., statistical analysis).

The Communication Process

The communication circuit used in the preceding example comprises a number of distinct elements. The circuit starts at one end with the mainframe computer or, more technically, the Data Terminal Equipment (DTE—a computer or machine which provides data in the form of digital signals at its output), continues with the front-end processor which acts as an interface between the Central Processing Unit (CPU) and the various input-output units, to the MODulator-DEModulator (MODEM—a type of Data Communication Equipment (DCE) that converts digital data to an analog signal for transmission on telephone circuits), to the telephone lines or any suitable transmission channel such as microwaves or radio waves, to another MODEM, to another interface (often such as the RS–232C serial interface), and finally to the microcomputer.

---

[1] Clinical Psychopharmacology Unit, Allan Memorial Institute, Department of Psychiatry, McGill University, Montreal, Quebec, Canada H3A 1A1

Along the communications circuit, the data (letters, numbers, and other symbols) are represented according to certain coding schemes. A scheme very widely used for computers to communicate with peripherals is the American Standard Code for Information Interchange or ASCII (Mackenzie, 1980). This code effectively uses 7 bits to represent 128 different symbols. These include the usual alphanumerical symbols found on a typewriter. For instance, upper case 'A' is represented as 100 0001 binary, corresponding to decimal value 65, whereas lower case 'a' is 110 0001, equivalent to decimal value 97, and so on. Some control characters are also available (decimal values 0–31), so called because they are acted upon by the computer rather than merely displayed. The most commonly used are probably 'carriage return' '(mnemonic: CR, decimal value = 13) and 'line feed' (LF, 12 decimal), which respectively bring the cursor or printhead to the leftmost position on a line and move to a new line. Other characters such as 'bell' (BEL, 7 decimal), 'backspace' (BS, 8 decimal) and 'form feed' (LF, 12 decimal) are fairly self-explanatory, but others are not so obvious.

In the case of a file transferred from a mainframe, each data line begins on a new line (LF) and terminates with a carriage return (CR). In addition, a device control character such as DC3 (19 decimal) might be inserted at the end of each line. It means 'reader-off,' i.e., the sender is not finished transmitting, more data is coming, and the sender will not accept input. The very last character, DC1 (17 decimal) means 'reader-on,' i.e., transmission has ended for now, input will be accepted. The communication protocol determines which control characters are used and how they are acted upon. It may vary from one system to another and it will be necessary to obtain that information from the system managers before establishing communications.

As mentioned before, ASCII is a widespread code for communications. Inside the computer at each end, the coding might be different. An IBM mainframe will use the Extended Binary Coded Decimal Interchange Code (EBCDIC) where 8 bits represent each symbol. Many microcomputers will use an 8 bit extended ASCII internally (the standard ASCII does not use the most significant bit which always has value 0). The necessary translation for communications will generally be done by the computer, in a manner transparent to the user.

There is another more important difference between internal data manipulation and external communications. The computer will generally move data around in a parallel manner. Each piece of information will typically be manipulated 8, 16, or 32 bits at a time, depending on the CPU word size. The electrical signals forming the bits each travel along a line or wire, but telephone lines and other channels do not have so many wires so the data need to be transmitted serially, one bit at a time. This conversion process is accomplished by a serial interface. There are more than one type of serial interface but the RS–232C is the most widely used on microcomputers. Simplifying to the extreme, this interface has a data register capable of parallel input (all bits of one character simultaneously) and serial output (all bits of one character one after the other) and vice-versa, with appropriate timing.

The telephone line not only forces serial transmission but it also requires that the digital pulses of the computer (e.g., 0 volts = 0, +5 volts = 1) be transformed or modulated using waves (e.g., 1070 Hz = 0, 1270 Hz = 1). This is accomplished by the modem. To obtain an orderly exchange of data, the modem needs to be controlled by the computer, via the serial interface and a wire cable allowing the use of up to 25 different signals.

Depending on the system you communicate with, transmission will take place in the either duplex or half-duplex. In duplex, the hardware allows sending and receiving of data at the same time (using different frequency bands) whereas in half-duplex, transmission occurs in one direction at a time. IBM mainframes use half-duplex communications.

In programming a serial interface or simply setting the parameters of a terminal emulator program, it is necessary to specify the speed at which the data will be transmitted along the channel. The RS–232C is designed to offer a range of 'Baud rates' between 50 and 19200. The Baud rate is the number of signaling elements per second. It can be understood as the number of bits per second (Bps) for the purpose of the current discussion, although the two are not always equivalent: techniques exist to transmit more than one bit per Baud.

A number of problems can arise during communication which can alter the nature of the signals and distort or destroy data. Noise on the telephone line, for instance, could interfere with the frequency of the signal and make a 0 appear as a 1 on arrival. The most reliable strategy would consist in sending the received message back to the sender and compare this copy with the original; but that would at least double transmission time, not to mention all the processing required to compare the messages.

Various methods exist to check for possible errors while maintaining a lower overhead (Lin & Costello, 1983). One is PARITY checking. Recall that the standard ASCII code uses only 7 bits while most microcomputers have a word length of at least 8 bits. During communications the eighth bit can be set or reset according to how many of the 7 character bits are set. For instance, enabling even parity would consist in setting the eighth bit when and only when there is an odd number of 1's in the remaining 7 bits such that overall there would always be an even number of 1's. This parity testing is usually carried out by the interface which will flag any problem.

Another method uses HAMMING CODES. This method associates a parity bit with bits 1, 3, 5, and 7, another parity bit with bits 2, 3, 6, and 7, and a third parity bit with bits 4, 5, 6, and 7. Upon character reception, these extra parity bits are computed from the received data and compared with those sent with the data. Depending on the pattern of change obtained, it can be determined which of the 7 character bits is faulty and correct it. For instance:

1) Data to be sent:
x1 x2x3 x4x5x6x7 = 1 00 0100
2) Transmitted data:
P1x1P2x2x3P3x4x5x6x7 = 0100010100
3) Data groups P1x1 x3 x5 x7 = 01 0 1 0
with even parity: P2x2x3 x6x7 = 000 00
P3x4x5x6x7 = 10100
4) Received data with error in bit x6:
0100010110
5) P's computed from received data:
P3 = 0 P2 = 1 P1 = 0
6) P's received with the data:
P3 = 1 P2 = 0 P1 = 0
7) Change in P's: C3 = 1 C2 = 1 C1 = 0
8) Decimal equivalent of C3C2C1 binary code: (110) = 6
9) Therefore bit 6 is incorrect:
received 1, change to 0
Data Code transmitted should be:
1 00 0100

The ability to isolate which bit was denatured during transmission costs two extra bits per character relative to simple parity checking. This overhead could become unacceptable: at low speed (e.g., 300 Bps), eight more minutes would be required to transfer an 80K characters file (80,000 char X 8 bits/300 Bps/60 seconds = 36 minutes, versus 44 minutes with 10 bits).

Data integrity is the crucial aspect of communications, particularly where file transfers are concerned. A number of protocols have been devised to achieve reliable communications. Here is a brief overview of the strategy used by KERMIT, a protocol developed at Columbia University (Da Cruz & Catchings, 1984):

- Communication takes place in half-duplex over ordinary transmission lines.
- ASCII characters are transmitted in packets of variable length (0–96) in alternate directions and a reply (positive or negative acknowledgment) is required for each packet.
- Only printable characters are used for transmission; non-printable characters (0 to 31) are prefixed with a special character (#) and converted for transmission by adding 32 to their decimal value.
- Each packet begins with a mark, normally SOH (ASCII 01 or CTRL-A), followed by a length field.
- The length is the number of ASCII characters in the packet following this field, including control characters (maximum = 94).
- The next character is the packet sequence number (0–63, wrapping around after a group of 64).
- Then comes a packet type identifier indicating whether the packet contains data, an acknowledgment, a command to be executed immediately, etc.

- Following is the actual contents of the packet, i.e., the data if any.
- The packet terminates with the block-check sequence.
- The system must react within a specified time interval; otherwise a time out occurs and the packet is retransmitted.

The standard error detection provided in the final block-check is an arithmetic checksum, which is the addition of the ASCII values of all the characters in the packet, excluding the mark and the check itself. The result can approach 12,000 (ASCII 127 × 94). The binary representation of this number is 14 bits long (10111011100000) thus two characters would be necessary to represent it fully. This represents a much lower overhead than the addition of 3 extra bits per character as in the Hamming code. The checksum method will leave some errors undetected since with up to 94 characters per sum, there are many combinations that can produce the same sum. According to the protocol designers, the probability of an undetected error is 1/4096 for a two-character checksum.

Another method of error detection allowed in the protocol is a 16 bit Cyclic Redundancy Check (CRC). Essentially, the CRC passes the characters through a shift register with feedback loops such that each bit of the transmitted message affects the block check character more than once. This method will detect all error bursts of 16 bits or less in length and 99.99% of longer ones (MacNamara, 1977).

With such a protocol, what would be the consequences of transmission errors?

- If the SOH is garbled, all characters become ignored until the next mark.
- If any other character in the packet is distorted into SOH, the rest of this packet is taken as a new one but its spurious nature will be caught at the length, sequence, or block-check level.
- If the length field is garbled into a larger value, the checksum will be absent or in any case wrong, leading to a retransmission. If the distortion causes a value smaller than the real length to arrive, then the system will hang, waiting for missing extra characters, until a preset time out is reached.
- If the sequence number, the type field, one or more data characters, or the checksum are distorted, the checksum should be wrong, causing retransmission of that packet.

Conclusion

Having a terminal emulator program at your disposal is certainly a cost efficient strategy since it allows your microcomputer to double up as a terminal.* This is fine if one simply needs access to a mainframe to execute sizable tasks. If the objective is to transfer data files between the two computers in order to use them on either machine, the program must provide reliability checks.

This text attempted to overview some of the basic technical aspects involved in terminal emulation. From the user's point of view at least, other aspects may be very significant such as full-screen editing capabilities (IBM 3270 emulation). These depend on such considerations as what the mainframe system supports and how extensively terminal-mode is used. Although not covered here, they would remain important aspects to consider in selecting or writing a program.

*A documented listing of a minimal terminal emulator program is available from the author. This program is written in BASIC for a Hewlett-Packard 9816. It uses some machine-dependent features and performs error detection but not correction. It can be used to learn and build from.

Expert Systems in Psychiatry

Michael Feinberg, M.D., Ph.D.,[1] and
Robert K. Lindsay, Ph.D.[1]

There is a documented shortage of psychiatrists in the United States (GMENAC, 1980), and the estimates of the prevalence of psychiatric illness used to develop this report were lower than the figures in recent population surveys (Myers et al., 1984). Further, most prescriptions for antidepressants are written by non-psychiatrists (Johnson, 1974; Ketai, 1978; Kline, 1974), and the great majority of depressed patients seen by a sample of primary care physicians were treated inappropriately (Weissman et al., 1981). These data highlight the need for improving the treatment provided to the majority of mentally ill patients. We believe that computers can act as consultants to non-psychiatrist clinicians, resulting in improved patient care.

The appropriate computer technology is a form of applied artificial intelligence called *expert systems*. Expert systems are computer programs that encode some of the knowledge used by experts in a particular field and apply an inference-making procedure to this knowledge. There are now several hundred expert systems in various stages of development, covering a broad range of disciplines, a few of which are in active application. Examples of the more mature systems include those used for molecular structure elucidation in organic chemistry (Lindsay et al., 1980), configuration of computer systems (McDermott, 1982), mineral exploration (Campbell et al., 1982), and analysis of pulmonary function tests (Aikins et al., 1982); *see* also Duda and Shortliffe (1983), and Buchanan and Shortliffe (1983).

Expert systems can make accurate diagnoses in internal medicine, even when the patient has several diagnoses. The performance of the program Caduceus (nee Internist) was tested on a group of CPC's (clinical-pathological conferences) from the *New England Journal of Medicine*. The program was correct as often as were the referring physicians, but less often than the expert consultants who discussed the cases (Miller et al., 1982). This record should be considered in light of the fact that the human experts were particularly knowledgeable in a delimited area of internal medicine, while the program's performance was tested on a wide range of cases. Other expert systems can do as well as the best human consultant, but in a narrower domain. These include the Casnet program for the diagnosis of glaucoma (Kulikowski & Weiss, 1982) and programs for acid-base/electrolyte disorders (Patil et al., 1982).

Some expert systems can explain the reasons for asking a question, making a diagnosis, or recommending a therapeutic regimen, although the explanations have tended to be superficial rather than phrased in terms of basic principles. Caduceus, for example, works well but offers no amenities to the user; in the current jargon, it is not user-friendly. In particular, it cannot explain why it reached a diagnosis other than by displaying its initial probability data and its calculations. The program as written has no concept of time, and cannot make use of the order in which symptoms occurred, or of such concepts as episodes of illness or the rate of onset of a symptom. Fagan and his associates (Horvitz et al., 1984) have used a similar, Bayesian method in an expert system for the differential diagnosis of lymphomas using data gathered from inspection of a slide. In this situation, there are no temporal relationships to account for.

Shortliffe (1976; Buchanan & Shortliffe, 1984) wrote perhaps the best known medical expert system, MYCIN, which can diagnose and make treatment recommendations for meningitis and septicemia. The group at Stanford went on to separate the control structure of MYCIN from its knowledge about infectious diseases. The resulting program, called EMYCIN (Essential MYCIN), can "reason" in any domain and thus forms the basis of a wide variety of expert systems (van Melle, 1981, 1984). Each new expert system can be written by constructing a new knowledge base in the form of if-then (production) rules with a minimum of "program-

---

ming" required. The principles involved have shaped the design of expert systems and are central to the work we are doing.

As we have noted, it is extremely important that an expert system be able to explain its behavior to the client. This is so for two reasons. First, it is necessary for client acceptance. Second, it is necessary if the client and program are to work together in a manner that makes use of their complementary abilities. MYCIN, and EMYCIN-based systems in general, have a primitive explanation facility derived from the rule-based style of programming itself. Since rules are a more-or-less transparent and modular form of knowledge representation, informing the client that decisions were reached via such-and-such a rule is readily possible. Insofar as the rules succeed in encapsulating meaningful knowledge, these "explanations" are valuable.

The example below shows a rule from an expert system for the Hamilton Rating Scale and the explanation based on the rule:

RULE 003

[This rule is tried in order to find out whether retardation is severe or worse.]
If: 1) Retardation is moderate or worse, and
  2) A: Interview is prolonged by slowed speech,
    B: Gait is slow-with-decreased-associated-movements, or
    C: Time to complete self-ratings is abnormally long
Then: It is definite (1.0) that retardation is severe or worse.
  9) Does slowed speech prolong the interview to a marked degree?
  ** WHY
[i.e., WHY is it important to determine whether interview is prolonged by slowed speech?]
[3.0] This will aid in determining whether retardation is severe or worse. It has already been established that
  [3.1] retardation is moderate or worse
  Therefore, if
  [3.2] 1) Interview is prolonged by slowed speech,
    2) Gait is slow-with-decreased-associated-movements, or
    3) Time to complete self-ratings is abnormally long
then
it is definite (1.0) that retardation is severe or worse.
[RULE 003]

However, some rules are necessary simply to control certain record keeping functions in the program, and when these are offered as part of explanation the result is often puzzling (e.g., "I asked for that datum because that is one of the things I need to know."). Furthermore, the rule set does not contain the reasons for its own construction, and so a more global explanation cannot be obtained from it.

Swartout (1981, 1983) has developed a more sophisticated explanation facility for an expert system. He constructed an expert system that explains its questions and actions in terms of underlying knowledge, such as basic physiology and pharmacology, by having the expert system incorporate that information and literally build its own higher level knowledge on the foundation of the underlying concepts. The examples below show two explanations of the reason for asking about serum potassium before prescribing digoxin. The first is from a rule-based system; the second, from Swartout's explanation system.

1) What is the level of serum potassium?
Enter numerical value = = = > why?
My top goal is to begin therapy. One step in doing that is to check sensitivities. I am now trying to check sensitivity due to potassium.

2) Please enter the value of serum-k:why?
The system is anticipating digitalis toxicity. Decreased serum-k causes increased automaticity, which may cause a change to ventricular fibrillation. Increased digitalis also causes increased automaticity. Thus, if the system observes decreased serum-k, it reduces the dose of digitalis due to deceased serum-k.
Please enter the value of serum-k:3.7.

There have been a few recent attempts to apply expert systems methods to psychiatry, and interest in these applications has been growing. Heiser and Brooks (1978; Brooks & Heiser, 1980) began a project, called HEADMED, in the late 1970's. Their program used EMYCIN (van Melle, 1981) and was designed to work backward from available medications, attempting to select the one that was indicated by rules that related drugs to symptoms. This system was never fully implemented.

A small system applying knowledge engineering methods was constructed in 1983 by two medical externs at Stanford University Medical School. That program, called BLUEBOX (Mulsant & Servan-Schreiber, 1984), contained about 175 rules written in EMYCIN. We studied and ran this program and discussed it with its authors at length prior to beginning our own efforts. Neither HEADMED nor BLUEBOX was ever subjected to validation tests.

Erdman (1983) developed two computer-based diagnostic models for depression, based on the advice and expertise of a psychiatrist. One model was represented as a "flowchart" of questions and answers; the second "decision theoretic" model was based on statistical relations of symptoms and illness. These models were applied to a limited sample of (eight) actual cases that were also analyzed by a group of psychiatrists and a group physicians (non-psychiatrists). Neither model correlated well with the average of the psychiatrists' recommendations; the flow chart model doing no better than a random selection, the probabilistic model doing slightly better (kappa = .44). However, Erdman found a positive effect of these models on the confidence of non-psychiatric users.

We employed three programming tools for expert systems in the pilot studies. Two of these, EMYCIN (van Melle, 1981) and AGE (Nii & Aiello, 1979), were made available to us on the SUMEX national computer resource for artificial intelligence in medicine, located at Stanford University and accessed over computer network (Tymnet). The third is a commercial programming system for expert systems, KEE, developed by Intellicorp of Palo Alto, and used on a Xerox 1108 and a Symbolics 3600 scientific workstation. We first used EMYCIN to develop a system to consult in the use of the Hamilton Rating Scale, a standard tool for evaluation of depression (Hamilton, 1960, 1967). This expert system taught us several important lessons about constructing expert systems in general and about using EMYCIN to do so. We also developed a pilot version of a rule-based inference system for the diagnosis of depression, derived from observation of clinical interviews by an expert diagnostician (Feinberg). This system was initially developed on SUMEX using the AGE system. The AGE software is not maintained as a production tool by the SUMEX staff, and access over the network is slow and limited to standard keyboad/CRT interactions. Our experiences in using EMYCIN and AGE on SUMEX via Tymnet also convinced us that we would make more rapid progress using local machines, once past the pilot stages. SUMEX served us very well for pilot work, but will not be adequate for more intensive work with a larger knowledge base.

We sought a more efficient alternative, and one of us (RKL) was able to obtain an academic grant from Intellicorp allowing us to use the KEE system. This is a commercial product which runs on sophisticated workstations such as the Xerox 1108. Intellicorp provides documentation, maintenance (including bug reporting by electronic mail), and training. We have been using KEE to develop an expert system on the somatic treatment of depression.

An Expert System for the Diagnosis of Depression

There has been a growing emphasis in American psychiatry on careful diagnosis using clearly defined clinical criteria (APA, 1980; Feighner et al., 1972; Feinberg & Carroll, 1982, 1983; Spitzer et al., 1975). These efforts have led to several lists of criteria for the diagnosis of psychiatric disorders. The "St. Louis" criteria (Feighner et al., 1972) were succeeded by the Research Diagnostic Criteria (RDC), formulated by researchers from St. Louis and New York (Spitzer et al., 1975). The RDC led directly to the criteria that are now quasi-official in American psychiatry, DSM-III (APA, 1980). All of these lists of criteria were based on a combination of clinical opinion and literature review.

These diagnostic systems have been shown to be acceptably reliable, but their validity has not been as well demonstrated.

The criterion lists mentioned above have emphasized the diagnosis of affective disorders (e.g., depression), reflecting earlier evidence that American psychiatrists tended to overdiagnose schizophrenia in preference to affective disorders (Cooper et al., 1972). Several groups in England and the United States have used multivariate statistics to differentiate subtypes of depression. Roth and his colleagues (Carney et al., 1965) published a discriminant index (the Newcastle Diagnostic Index) for distinguishing "endogenous" from "neurotic" depressed patients. Kiloh et al. (1972) confirmed their results in a separate population. We have done similar work, deriving two discriminant indices for separating endogenous depressed (ED) patients (unipolar or bipolar) from those with nonendogenous ("neurotic") depression (ND). We cross-validated these indices in separate groups of patients, and also validated them against an external standard, the dexamethasone suppression test (Feinberg & Carroll, 1982, 1983). The Newcastle and Michigan Indices tend to contain the same symptoms, and both tend to differ from the criterion lists based on "clinical wisdom."

We have continued our work on the differential diagnosis of depression using an expert system written by Fagan and co-workers at Stanford (Horvitz et al., 1984). This program, Pathfinder, is being developed to distinguish among lymphomas on the basis of data gathered from inspection of a slide, using modified Bayesian statistics and logic similar to that of Internist–1 (Miller et al., 1982). We have applied Pathfinder to the task of distinguishing endogenous and nonendogenous depression. The knowledge base we provided includes marginal probabilities computed on data from the patients studied by Feinberg and Carroll (1982), specifically, the probability that a particular symptom will be present at a certain intensity in each diagnostic group and the probability that a patient with a given level of a symptom will belong to each diagnostic group. We used the Pathfinder program to assign diagnoses to a separate group of patients, with the results shown in the table. The program computes the probability of the patient's belonging to each diagnostic group, and we have assigned the patient to a group if the probability of his membership is above 0.66 (i.e., 2:1 odds or better). As expected, the results are almost exactly those obtained using the Michigan Discriminant Index for separating unipolar ED from ND patients (Feinberg & Carroll, 1982).

Pathfinder Diagnosis

		ED	?	ND	Total
Clinical	ED	17	5	4	26
Diagnosis	ND	6	4	15	25
					51

Forty-two of the 51 patients in this group were classified by the program (82%). Of these, 32 of 42 (76%) were classified correctly. This is far better than chance but we are trying to improve this by adding clinical features not included in the discriminant index.

The Pathfinder program can be run in two modes. The first, used to produce the results above, calculates the probability of each diagnosis from the (complete) data for each patient, based on the marginal probabilities in the knowledge base. In the second mode, more consistent with what one usually expects from an expert system, the program sequentially asks for the additional information that will be most useful in reaching a diagnosis until it can assign a sufficiently high probability to the patient's belonging to one diagnostic group. An example of computer-clinician dialogue for each mode is available from the authors. Our work to date has shown that the program can reach acceptably accurate diagnoses, but we will not have an accurate picture of its suitability for our particular problem until we have added more diagnoses and more clinical features to the knowledge base.

B-1 **Psychopharmacology—A Recurring Bibliography—**

Vol. 21, No. 2, 1985

167 **Introduction—***Natalie Reatig*

Pharmacotherapy for ADD-H Adolescents Workshop —

169 Follow-up Studies on Outcome of Hyperactive Children — *Gabrielle Weiss*

178 Adolescent Outcome of Hyperactive Children Treated with Stimulants in Childhood: A Review — *Lily Hechtman*

192 Pharmacotherapy in ADD Adolescents with Special Attention to Multimodality Treatments — *Ronald T. Brown, Kathi A. Borden, and Stephen R. Clingerman*

212 Prevalence of Medication Treatment for Hyperactive Adolescents — *Daniel J. Safer and John M. Krager*

216 A Review of Studies of Drug Treatment Efficacy with Attention Deficit Disorder with Hyperactivity in Adolescents — *Christopher K. Varley*

222 Pharmacological Treatment of Attention Deficit Disorder, Residual Type (ADDRT, "Minimal Brain Dysfunction," "Hyperactivity" in Adults) — *Paul H. Wender, David R. Wood, and Fred W. Reimherr*

232 New Drug Trials in Attention Deficit Disorder — *Judith L. Rapoport, Alan Zametkin, Maureen Donnelly, and Deborah Ismond*

237 Diagnosing ADD-H in Adolescents — *Rachel Gittelman and Salvatore Mannuzza*

243 Issues in the Study of Adolescent ADD-Hyperactivity — *C. Keith Conners*

A Summary of the Workshop Proceedings

251 Pharmacotherapy of ADD in Adolescents: What Do We Know, Where Should We Go, How Should We Do It? — *Dennis P. Cantwell*

Pharmacotherapy and Mental Retardation Workshop —

258 Emotional Problems in the Mentally Retarded: The Need for Assessment and Treatment — *Johnny L. Matson*

262 Issues in Pharmacology with the Mentally Retarded — *Susan Mouchka*

268 Psychoactive Drug Use in Public and Community Residential Facilities for Mentally Retarded Persons — *James Intagliata and Chris Rinck*

279 A National Study of Prescribed Drugs in Institutions and Community Residential Facilities for Mentally Retarded People — *Bradley K. Hill, Elizabeth A. Balow, and Robert H. Bruininks*

285 Establishing Socially Validated Drug Research in Community Settings — *Martin Agran and James E. Martin*

291 Prevalence and Efficacy of Stimulant Drug Use with Mentally Retarded Children and Youth — *Kenneth D. Gadow*

304 Psychopharmacology in the Mentally Retarded and a Few Related Issues — *C. Thomas Gualtieri and J.M. Keppel*

310 Behavioral Interactions Induced by Chronic Neuroleptic Therapy in Persons with Mental Retardation — *Stephen R. Schroeder and C. Thomas Gualtieri*

316 Diagnosis and Pharmacotherapy of Schizophrenia in the Retarded — *Frank J. Menolascino, Stephen L. Ruedrich, Charles J. Golden, Ph.D., and James E. Wilson, Pharm.D.*

Workshop Summary —

323 Issues and Future Research Directions of Pharmacotherapy in Mental Retardation — *Stephen R. Schroeder*

Brief Report —

327 An Applied Tardive Dyskinesia Monitoring System (ATDMS) — *John E. Kalachnik*

329 Pharmacotherapy and Mental Retardation/Developmental Disability: A Bibliography — *Natalie Reatig*

Adverse Drug Reaction —

334 "Time-less" Risks (A Hazard of Risk Assessment: The Example of Seizure and Antidepressants — *Paul Leber*

Articles —

339 ACTeRS Useful in Screening Learning Disables from Attention Deficit Disordered (ADD-H) Children — *Rina K. Ullmann*

345 Carbamazepine in Tardive Dyskinesia — *András Perényi and Dániel Sztanisz-láv*

347 Biochemistry of Alzheimer's Disease — *Ira R. Berry and Lionel Borkan*

B-1 **Psychopharmacology— A Recurring Bibliography—**

Vol. 21, No. 3, 1985

357 **In the Pipeline—***Barry Blackwell*

23rd Meeting of the ACNP—1984— Abridged Proceedings —

New Approaches to the Genetics of Psychiatric Disorders —

361 Additional Cerebrospinal Fluid Proteins Found in Schizophrenia and Creutzfeldt-Jakob Disease — *Michael G. Harrington and Carl R. Merril*

365 Cerebral Ventricular Enlargement as a Possible Genetic Marker for Schizophrenia — *Lynn E. DeLisi, Lynn R. Goldin, Joel R. Hamovit, M. Elizabeth Maxwell, David Kurtz, John I. Nurnberger, and Elliot S. Gershon*

Bright Light, Melatonin, and Biological Rhythms: Implications for the Affective Disorders —

368 Treating Phase Typed Chronobiologic Sleep and Mood Disorders Using Appropriately Timed Bright Artificial Light — *Alfred J. Lewy, Robert L. Sack, and Clifford M. Singer*

New Strategies in the Therapy of Affective Disorders —

373 The Serotonin/Norepinephrine-Linked Beta-Adrenoceptor System and the Mode of Action of Antidepressant — *Elaine Sanders-Bush, P. Jeffrey Conn, and Fridolin Sulser*

379 Serotonergic Modulation of Cortical Rat Noradrenergic System in the Mechanism of Action of Antidepressant Drugs — *N. Brunello, I. Mocchetti, A. Volterra, V. Cuomo, and G. Racagni*

385 The GABA Hypothesis of Depression and Antidepressant Drug Action — *G. Bartholini, K.G. Lloyd, B. Scatton, B. Zivkovic, and P.L. Morselli*

Do We Need CSF Studies in Clinical Pharmacology? —

389 CSF, Plasma, and Urine: What Do Concomitant Measurements of Norepinephrine and Its Metabolites Mean? — *Markku Linnoila, Elizabeth A. Lane, Sally Guthrie, Ioanis Parashos, Matthew Rudorfer, and William Z. Potter*

396 Can CSF Measures Distinguish Among Schizophrenia, Depression, Movement Disorders, and Dementia? — *Stephen M. Stahl*

400 Clinical Implications of Neurochemical Mechanisms of Appetite Regulation—Neuropeptidergic Regulation of Feeding — *John E. Morley, Blake A. Gosnell, Dean D. Krahn, James E. Mitchell, and Allen S. Levine*

406 Peptide-Catecholamine Interaction: Feeding and Satiety — *Robert D. Myers*

412 Brain Neurotransmitters and Appetite Regulation — *Sarah F. Leibowitz*

419 Disturbances of Norepinephrine Metabolism and α-2 Adrenergic Receptor Activity in Anorexia Nervosa: Relationship to Nutritional State — *Walter H. Kaye, Harry E. Gwirtsman, C. Raymond Lake, Larry J. Siever, David C. Jimerson, Michael H. Ebert, and Dennis L. Murphy*

Pharmacologic Model of Anxiety in Man —

424 Isoproterenol-Induced Anxiety States — *Robert Pohl, John Rainey, Aurelio Ortiz, Richard Balon, Heminder Singh, and Richard Berchou*

428 The Lactate Infusion Model — *Jack M. Gorman, Donald Dillon, Abby J. Fyer, Michael R. Liebowitz, and Donald F. Klein*

434 Panic Anxiety and Lactate Metabolism — *John M. Rainey, Jr., Charles E. Frohman, Ken Warner, Stewart Bates, Robert B. Pohl, and Vikram Yeragani*

Biological and Behavioral Reactions to Stress —

438 Regulation of Adrenocorticotropin Release From the Anterior Pituitary — *Terry Reisine*

443 Melancholia in Rodents: Neurobiology and Pharmacology — *Fritz A. Henn, Joel Johnson, Emmeline Edwards, and David Anderson*

447 Neurochemical Basis of Stress-Induced Depression — *Jay M. Weiss and Prudence Goodman Simson*

458 Serotonin-Behavior Interactions in Vervet Monkeys — *Michael T. McGuire and Michael J. Raleigh*

Enkephalin-Endorphins: Emotional Stress, Depression, and the Immune System —

464 Selectivity of Opioid Agonists and Antagonists for the Various Opioid Receptor Types — *A.E. Takemori and P.S. Portoghese*

466 Opioid Peptides in the Adrenal Pituitary Axis — *Christopher J. Evans, Elizabeth Erdelyi, and Jack D. Barchas*

472 The Alpha MSH-Specific and Arcuate Pro-Opiomelanocortin Neuronal Systems of the Hypothalamus: Observations on Their Connectivity and Response to Colchicine Treatment — *Karl M. Knigge, Diane T. Piekut, and Shirley A. Joseph*

476 Depression, Hypothalamic-Pituitary-Adrenocortical Activity, and Lymphocyte Function — *Ziad Kronfol and J. Daniel House*

479 Involvement of Opioid Peptides in the Analgesic, Immunosuppresive, and Tumor-Enhancing Effects of Stress — *James W. Lewis, Yehuda Shavit, Gregory W. Terman, Linda R. Nelson, Fredricka C. Martin, Robert Peter Gale, and John C. Liebeskind*

485 Endorphins, Immune Function, and Cancer — *John E. Morley, Neil Kay, John Allen, Timothy Moon, and Charles J. Billington*

489 The Ying-Yang Hypothesis of Opioid Peptide Immunomodulation — *Nicholas P. Plotnikoff*

Psychobiological Markers for Schizophrenia: State of the Art and Future Perspectives —

490 Introduction and Summary — *Joseph Zubin*

497 Are There State-Dependent Markers in Schizophrenia? — *Daniel P. van Kammen, Jules P. Rosen, Jeffrey Peters, Robert Fields, and Welmoet B. van Kammen*

503 Vulnerability to Schizophrenia: Childhood Indicators Predict Adult Outcome — *Ernest Hartmann, Walter Mitchell, Patricia Brune, and Daniel Greenwald*

509 Distractibility as a Marker of Vulnerability to Schizophrenia — *Bonnie Spring*

513 Neurophysiological Aspects of Information Processing in Schizophrenia — *Stuart R. Steinhauer*

518 Sensory and Perceptual Behavioral Markers of Schizophrenia — *Mitchell L. Kietzman*

Neuropeptides Modulating Dopaminergic Function: New Horizons for the Dopamine Hypothesis of Schizophrenia —

523 Cholecystokinin Potentiates Dopamine-Mediated Behaviors in the Nucleus Accumbens, a Site of CCK-DA Co-Existence — *Jacqueline N. Crawley*

Toxic Effects of Psychomotor Stimulants —

528 Persistent Effects of Amphetamine, *p*-Chloroamphetamine, and Related Compounds on Central Dopamine and Serotonin Neurons in Rodents — *Ray W. Fuller*

Alternate Treatment Strategies in Schizophrenia: Focus on the Deficit State —

533 High-Dose Versus Low-Dose Strategies in the Treatment of Schizophrenia — *John M. Kane, Arthur Rifkin, Margaret Woerner, Gerald Reardon, Dolores Kreisman, Richard Blumenthal, and Michael Borenstein*

Panic Disorder and Major Depression: Epidemiology, Family Studies, Biologic, and Treatment Response Similarities —

538 The Epidemiology of Anxiety Disorders: A Highlight of Recent Evidence — *Myrna M. Weissman, Philip J. Leaf, Charles E. Holzer III, and Kathleen R. Merikangas*

543 Major Depression and Panic Disorder: A Family Study Perspective — *James F. Leckman, Myrna M. Weissman, Kathleen R. Merikangas, David L. Pauls, Brigitte A. Prusoff, and Kenneth K. Kidd*

546 Neuroendocrine Abnormalities in Panic Disorder — *Peter P. Roy-Byrne, Thomas W. Uhde, Philip W. Gold, David R. Rubinow, and Robert M. Post*

551 Panic Disorder and Major Depression: Biological Relationships — *Peter P. Roy-Byrne and Thomas W. Uhde*

555 Lactate Infusion in Patients With Depression and Anxiety — *Patrick J. McGrath, Jonathan W. Stewart, Wilma Harrison, Frederic M. Quitkin and Judith Rabkin*

558 Effect of Panic Attacks on the Treatment of Atypical Depressives — *Michael R. Liebowitz, Frederic M. Quitkin, Jonathan W. Stewart, Patrick J. McGrath, Wilma Harrison, Judith Rabkin, Elaine Tricamo, Jeffrey S. Markowitz, and Donald F. Klein*

562 Panic Attacks in Outpatients With Depression: Response to Antidepressant Treatment — *Donald S. Robinson, Allen Kayser, John Corcella, Desmonde Laux, Kevin Yingling, and Diantha Howard*

Hormones and Depression—An Update —

568 Hormones and Depression—Conceptual Transitions — *Uriel Halbriech*

Peripheral Models for the Study of Neurotransmitter Receptors in Man —

573 Yohimbine and Clonidine Recognize Different States of Adrenergic Receptors on Human Platelets: Reconsideration of Studies on Platelet Alpha-2 Receptors in Depressive Illness — *John E. Piletz and Angelos Halaris*

579 Nocturnal Serum Melatonin in Major Depressive Disorder Before and After Desmethylimipramine Treatment — *Richard P. Brown, Stanley Caroff, James J. Kocsis, Jay Amsterdam, Andrew Winokur, Peter Stokes, and Alan Frazer*

Patterns of Cognitive Effects of Somatic Therapies —

582 Effect of Neuroleptic Treatments on Attention, Information Processing, and Thought Disorder — *Herbert E. Spohn, Lolafaye Coyne, Fred Mittleman, Jan Larson, Mary Johnston, Judy Spray, and Kenneth Hayes*

Brain Imaging in Psychiatry: New Developments —

588 Magnetic Resonance Imaging Studies of Schizophrenia — *Robert C. Smith, Richard Baumgartner, Marcos Calderon, Awatif Affas, G.K. Ravichandran, and I. Donald Peters*

595 Dopamine Receptor Binding of C-11-3-N-Methylspiperone in the Caudate in Schizophrenia and Bipolar Disorder: A Preliminary Report — *Dean F. Wong, Henry N. Wagner, Jr., Godfrey Pearlson, Robert F. Dannals, Jonathan M. Links, Hayden Ravert, Alan Wilson, Sudhir Suneja, Eythor Bjorvvinssen, Michael J. Kuhar, and Larry Tune*

Studies of Peripheral Monoamine Receptors in Affective Illness —

599 Platelet Alpha-Adrenergic Receptor Function in Affective Disorders and Schizophrenia — *Marian S. Kafka, Larry J. Siever, John I. Nurnberger, Thomas W. Uhde, Steven Targum, Dermot M.J. Cooper, Daniel P. van Kammen, and Nancy S. Tokola*

603 Studies of Beta-Adrenergic Receptors in Leukocytes of Patients With Affective Illness and Effects of Antidepressant Drugs — *Ghanshyam N. Pandey, Philip Janicak, and John M. Davis*

Social Phobias: Diagnosis, Pathophysiology, and Treatment —

610 Psychopharmacological Treatment of Social Phobia — *Michael R. Liebowitz, Jack Gorman, Abby Fyer, Raphael Campeas, Andrew Levin, Sharon Davies, and Donald F. Klein*

615 Behavioral Treatment of Social Phobia — *Isaac Marks*

Improvement With Antidepressants: Timing and Relationship to Biochemical Events —

619 Delayed Biochemical Changes Following Antidepressant Treatment — *Michael F. Sugrue*

Pharmacogenetics: A Preclinical and Clinical Perspective —

623 Molecular Basis of Drug-Resistance Mutations in C. Elegans — *James B. Rand and Richard L. Russell*

631 Biophysical Alterations in Cell Membranes Associated With Psychotherapeutic Drug Exposure, Psychopathology, and Aging — *George S. Zubenko and Bruce M. Cohen*

641 Relevance of Genetic Variability to Clinical Psychopharmacology — *Bruce M. Cohen and George S. Zubenko*

Noradrenergic Mechanisms and the Drug Withdrawal Syndrome —

651 Adrenergic Agonist Therapy in Alcohol Withdrawal States in Man — *Paul Cushman, Jr., William Lerner, and Michael Cramer*

Targeting the Central Nervous System: New Drug Delivery Technologies for Psychotropic Agents —

657 Chemical Approaches to Drug Delivery to the Central Nervous System — *Colin R. Gardner*

663 Peripheral Models for the Study of Neurotransmitter Receptors in Man — *Stephen M. Stahl*

672 Implantable Narcotic Antagonists: A Possible New Treatment for Narcotic Addiction — *C. Nora Chiang, Akira Kishimoto, Gene Barnett, and Leo E. Hollister*

Pharmacologic Challenge Strategies in Alzheimer's Disease: Basic and Clinical Issues —

676 Cognitive and Behavioral Sensitivity to Scopolamine in Alzheimer Patients and Controls — *Trey Sunderland, Pierre Tariot, Edward A. Mueller, Dennis L. Murphy, Herbert Weingartner, and Robert M. Cohen*

680 Low- and High-Dose Naloxone in Dementia of the Alzheimer Type — *Pierre N. Tariot, Trey Sunderland, Herbert Weingartner, Dennis L. Murphy, Martin R. Cohen, and Robert M. Cohen*

Poster Session —Editor's Choice

683 The Window of Vulnerability in the Ontogeny of the Dopamine Receptor — *Jeanette C. Miller and Arnold J. Friedhoff*

686 Depression in Adults With a History of Prenatal DES Exposure — *Heino F.L. Meyer-Bahlburg, Anke A. Ehrhardt, Jean Endicott, Norma P. Veridiano, E. Douglas Whitehead, and Felix H. Vann*

690 Cortisol and Prolactin Responses to Dexamethasone in Major Depression, Chronic Pain, and Chronic Pain With Major Depression — *Joseph H. Atkinson, Jr., Edwin F. Kremer, S. Craig Risch, and David S. Janowsky*

694 Evidence for a Daily Rhythm of Plasma HVA in Normal Controls But Not in Schizophrenic Patients — *Allen R. Doran, David Pickar, Rodrigo Labarca, Patrice Douillet, Owen M. Wolkowitz, John W. Thomas, Alex. Roy, and Steven M. Paul*

698 Imipramine for Treatment of Chronic Depression — *James H. Kocsis, Allen Frances, J. John Mann, John Sweeney, Carlyle Voss, Barbara Mason, and Richard P. Brown*

701 A New Postsynaptic Serotonin Receptor Agonist Suitable for Studies in Humans — *Edward A. Mueller, Dennis L. Murphy, Trey Sunderland, and Julia Jones*

705 Addition of Estrogen to Imipramine in Female-Resistant Depressives — *Joseph Zohar, Baruch Shapira, Gerald Oppenheim, Frank J. Ayd, and Robert H. Belmaker*

707 Lidocaine Kindling is Accompanied by an Increase in Apomorphine Stereotype and Mesolimbic Dopamine D Receptor Density — *John G. Csernansky, Cynthia A. Csernasky, Seth A. Glick, and Leo E. Hollister*

Vol. 21, No. 4, 1985

RATING SCALES AND ASSESSMENT INSTRUMENTS FOR USE IN PEDIATRIC PSYCHOPHARMACOLOGY RESEARCH

713 **From the Editor's Desk —**

714 **Introduction to This Issue —** ***Judith L. Rapoport and C. Keith Conners***

Demographic Data and Family History —

719 *Documentation of Demographic Data and Family History of Psychiatric Illness — *Magda Campbell and Michael Palij*

722 Demographic Template — *Magda Campbell*

728 ROS (Research Obstetrical Scale) — *Arnold J. Sameroff, R. Seifer, and M. Zax*

731 Prior Medication Record — *NIMH*

Psychiatric Interviews —

737 *Psychiatric Interviews Suitable for Use in Research With Children and Adolescents — *Helen Orvaschel*

747 CGAS (A Children's Global Assessment Scale) — *David Shaffer, Madelyn S. Gould, James Brasic, Paul Ambrosini, Prudence Fisher, Hector Bird, and Satwant Aluwahlia*

749 Rutter-Graham Psychiatric Interview for Children — *Michael Rutter and Philip Graham*

753 Children's Psychiatric Rating Scale (Scoring) — *Barbara Fish*

765 Children's Psychiatric Rating Scale — *NIMH*

Neurological Examinations —

773 Revised Physical and Neurological Examination for Subtle Signs — *Martha Bridge Denckla*

780 Scoring for Revised Physical and Neurological Examination for Subtle Signs — *Martha Bridge Denckla*

793 PANESS (Physical and Neurological Examination for Soft Signs) — *NIMH*

Diagnosis —

803 *DSM-III-R Pediatric Psychopharmacology — *Judity L. Rapoport*

Rating Scales and Checklists for Psychopharmacologic Trials —

809 *Rating Scales and Checklists for Child Psychopharmacology — *C. Keith Conners and Russell A. Barkley*

816 Parent Symptom Questionnaire — *C. Keith Conners*

823 Teacher Questionnaire — *C. Keith Conners*

828 Teacher Questionnaire (Follow-up School Report) — *C. Keith Conners*

832 IGRS (Inpatient Global Rating Scale) — *C. Keith Conners*

835 Child Behavior Rating Form — *Craig Edelbrock*

839 CGI (Clinical Global Impression) Scale — *NIMH*

845 The Aberrant Behavior Checklist — *Michael G. Aman, Nirbhay N. Singh, Alistair W. Stewart, and Carolyn J. Field*

851 GSS (General Scoring Sheet)—Basic — *NIMH*

Measures of Social Skills —

855 *Development of a Rating Scale to Measure Social Skills in Children: The Matson Evaluation of Social Skills With Youngsters (MESSY) — *Johnny L. Matson, Anthony F. Rotatori, and William J. Helsel*

861 Matson Evaluation of Social Skills With Youngsters (MESSY): (Teacher Rating Form) — *Johnny L. Matson and Karen Esveldt-Dawson*

865 Matson Evaluation of Social Skills With Youngsters (MESSY): (Self-Rating Form) — *Johnny L. Matson and Karen Esveldt-Dawson*

869 Social Interaction Observation Code — *Howard Abikoff, Diane Martin, and Rachel Gittelman*

Performance Measures —

**PLEASE NOTE: All references in this paper are presented in a single reference section to be found on pages 1111-1124.*

877 *Assessing Drug Effects on Academic Performance — Kenneth D. Gadow and H. Lee Swanson
887 *Measures of Cognitive Functioning Appropriate for Use in Pediatric Psychopharmacology Research Studies — James M. Swanson
891 *The Computerized Continuous Performance Test — C. Keith Conners
893 *Measuring Activity Level in Children — C. Keith Conners
898 Hillside Behavior Rating Scale (Behavior During Testing) — Rachel Gittelman and Donald Klein
901 Classroom Observation Code: A Modification of the Stony Brook Code — Howard Abikoff and Rachell Gittelman

Ratings for Attention Deficit Disorders —

913 *Some Thoughts on the Diagnosis of ADD-H in Adolescents — Rafael Klorman
915 Introduction to the Use of ACTeRS — Rina K. Ullmann, Esther K. Sleator, and Robert L. Sprague
917 ACTeRS (ADD-H Comprehensive Teacher's Rating Scale) —
921 ADD-H Adolescent Self-Report Scale — C. Keith Conners and Karen C. Wells
923 Parent Questionnaire of Teenage Behavior (Modified Conners) — Rachel Gittelman
925 Self-Evaluation (Teenager's) Self-Report — Rachel Gittelman
927 AQCC (Adult Questionnaire-Childhood Characteristics) Scale — Paul H. Wender
929 Bibliography on Rating and Assessment Instruments for Attention Deficit Disorder (ADD) — Natalie Reatig

Ratings for Anxiety Disorders —

933 Ratings for Anxiety Disorders — Rachel Gittelman
934 Children's Manifest Anxiety Scale: Parent Ratings — Rachel Gittelman
936 Children's Manifest Anxiety Scale: Child Ratings — Rachel Gittelman
939 Parent's Questionnaire (Modified Conners): Anxiety and Mood Items Added — Rachel Gittelman
945 Teacher Rating Scale ((Modified Conners): Anxiety and Mood Items Added — Rachel Gittelman

Ratings for Childhood Depression —

951 *Scales of Potential Use in the Psychopharmacologic Treatment of Depressed Children and Adolescents — Theodore A. Petti
957 DMS-III Symptom Checklist for Major Depressive Disorders — Javad Kashani, Donald McKnew, and Leon Cytryn
959 BID (The Bellevue Index of Depression) — Theodore A. Petti
969 PNID (Peer Nomination Index of Depression — M. M. Lefkowitz and E. Tesing
972 SADLI (School Age Depression Listed Inventory) — Theodore A. Petti
976 Interview for the SADLI — Theodore A. Petti
979 Children's Depression Rating Scale-Revised — Elva O. Poznanski
991 ISC (The Interview Schedule for Children) — Maria Kovacs
995 CDI (The Children's Depression Inventory) — Maria Kovacs

Ratings for Eating Disorders —

1001 *Rating Scales in the Eating Disorders — Katherine A. Halmi

---

*PLEASE NOTE: All references in this paper are presented in a single reference section to be found on pages 1111-1124.

1004 Anorexic Behavior Scale — *Peter D. Slade*

1005 Anorectic Attitude Questionnaire — *Solomon C. Goldberg, Katherine A. Halmi, and Elke D. Eckert*

1008 Eating Attitudes Test — *David M. Garner and Paul E. Garfinkel*

1009 Eating Disorder Inventory — *David M. Garner, M. P. Olmsted, and J. Polivy*

1011 Binge Scale Questionnaire — *Raymond C. Hawkins and Pamelia F. Clement*

1013 Binge-Eating Questionnaire — *Katherine A. Halmi, James R. Falk, and Estelle Schwartz*

1017 Bulimia Interview Form — *Timothy Walsh and Madeline Gladis*

1025 Eating Disorders Questionnaire — *James E. Mitchell*

Ratings for Autism —

1047 ***Behavioral and Cognitive Measures Used in Psychopharmacological Studies of Infantile Autism — *Magda Campbell and Michael Paliz***

1053 CARS (Childhood Autism Rating Scale) — *E. Schopler, R. J. Reichler, and B. R. Renner*

Ratings for Obsessive-Compulsive Disorders —

1057 The Leyton Obsessional Inventory-Child Version — *Carol J. Berg, Judith L. Rapoport, and Martine Flament*

Rating for Adverse Effects —

1063 ***Measurement of Side Effects Including Tardive Dyskinesia — *Magda Campbell***

1067 DOTES (Dosage Record and Treatment Emergent Symptom Scale) — *NIMH*

1069 TESS (Treatment Emergent Symptoms Scale—Write-In) — *NIMH*

1073 STESS (Subjective Treatment Emergent Symptoms Scale) — *NIMH*

1077 AIMS (Abnormal Involuntary Movement Scale) — *NIMH*

1081 Protocol for Rating Drug-Related AIMS, Stereotypies, and CPRS Assessments — *Magda Campbell*

1082 Timed Stereotypies Rating Scale — *Magda Campbell*

1085 **Laboratory Tests for Drug Studies — *Judith L. Rapoport***

Measures of Medication Compliance —

1089 *Measurement of Compliance — *Esther K. Sleator*

Grant Support and Ethical Issues —

1097 The Grant Support Program of the Pharmacologic and Somatic Treatment Research Branch — *Natalie Reatig*

1100 DHHS Internal Policies for Reviewing Protections to Human Subjects in Research — *Natalie Reatig*

1105 Ethical Issues in Research With Children: A Bibliography — *Natalie Reatig*

1111 **References for All Starred * Papers —**

***PLEASE NOTE:** *All references in this paper are presented in a single reference section to be found on pages 1111-1125.*

Psychopharmacology—A Recurring Bibliography

The bibliography below is offered to our readers to alert them to recent papers on psychopharmacology from the world literature. It was computer-generated by the Medical-Literature Analysis and Retrieval System (MEDLARS) of the National Library of Medicine, National Institutes of Health, and represents papers which were entered into the system during the 3 months before the *Bulletin* went to press.

The subject headings from Index Medicus were selected by the National Institute of Mental Health to reflect significant current interest of the international scientific community. Some nonrelevant citations may appear, and some relevant ones may be absent, but this is usual for machine-generated searches.

BIBLIOGRAPHY

ACEPROMAZINE

Increased mortality in gray wolves captured with acepromazine and etorphine hydrochloride in combination. Tobey RW, et al. **J Wildl Dis** 1985 Apr;21(2):188-90

ACETYLCHOLINE

Modulation of choline transport and acetylcholine synthesis in synaptosomes from different brain regions. Nordberg A, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 Mar;56(3):193-8

Cadmium inhibition of [3H]acetylcholine secretion in guinea-pig ileum myenteric plexus. Alberts P, et al. **Acta Physiol Scand** 1985 Jun; 124(2):313-6

The effects of adenosine and of some adenosine analogues on the concanavalin A-or acetylcholine-induced histamine release from human adenoidal mast cells. Delmich K, et al. **Agents Actions** 1985 Apr; 16(3-4):141-3

Immunological modulation of cholinergic histamine release in isolated rat mast cells. Masini E, et al. **Agents Actions** 1985 Apr; 16(3-4):152-4

The modulation of acetylcholine release by noradrenaline, GABA and related compounds. Beani L, et al. **Ann Ist Super Sanita** 1984; 20(1):17-9

Acetylcholine and histamine interact supra-additively on bronchomotor tone in guinea-pigs in vivo: a possible consequence of the relationship between airways resistance and calibre. Stewart AG, et al. **Arch Int Pharmacodyn Ther** 1985 Jan;273(1):33-46

Declining catecholamine secretion in adrenal medulla on prolonged stimulation with acetylcholine. Bevington A, et al. **Biochem Pharmacol** 1985 May 1;34(9):1497-500

Thyroliberin (TRH), 6-methyl-5-oxothiomorpholinyl-3-carbonyl histidylproline amide and histidylproline diketopiperazine do not affect the release of [3H]-acetyl choline and [3H]-choline from rat brain tissue cubes. Hedley D, et al. **Biochem Pharmacol** 1985 Apr 15; 34(8):1341-3

Blockade of the diazepam-induced increase in rat striatal acetylcholine content by the specific benzodiazepine antagonists ethyl-beta-carboline-3-carboxylate and Ro 15-1788. Kolasa K, et al. **Brain Res** 1985 Jun 17;336(2):342-5

Light evoked release of acetylcholine in response to a single flash: cholinergic amacrine cells receive ON and OFF input. Massey SC, et al. **Brain Res** 1985 Mar 4;328(2):374-7

Synthesis of acetylcholine and gamma-aminobutyric acid by dissociated cerebral cortical cells in vitro. Thomas WE. **Brain Res** 1985 Apr 15; 332(1):79-89

Acetylcholine release from rat atria can be regulated through an alpha 1-adrenergic receptor. Wetzel GT, et al. **Circ Res** 1985 May; 56(5):763-6

Effect of secretagogues on pancreatic exocrine secretion in the monkey and the dog. Iwatsuki K, et al. **Clin Exp Pharmacol Physiol** 1985 Jan-Feb;12(1):67-72

Comparative actions of GABA and acetylcholine on the Xenopus laevis lateral line. Bobbin RP, et al. **Comp Biochem Physiol [C]** 1985; 80(2):313-8

Action of acetylcholine and antagonists on somata isolated from locust central neurons. Suter C, et al. **Comp Biochem Physiol [C]** 1985; 80(2):221-9

Neurochemical evidence for the release of acetylcholine from the guinea-pig ileum myenteric plexus by capsaicin. Barthó L, et al. **Eur J Pharmacol** 1985 Mar 26;110(1):125-7

Real-time measurements of acetylcholine-induced release of ATP from bovine medullary chromaffin cells. Rojas E, et al. **FEBS Lett** 1985 Jun 17;185(2):323-7

Human pancreatic acinar cells: studies of stimulus-secretion coupling. Petersen OH, et al. **Gastroenterology** 1985 Jul;89(1):109-17

Mast cell heterogeneity in response to cholinergic stimulation. Masini E, et al. **Int Arch Allergy Appl Immunol** 1985;77(1-2):184-5

Rapid changes in synaptic vesicle cytochemistry after depolarization of cultured cholinergic sympathetic neurons. Johnson MI, et al. **J Cell Biol** 1985 Jul;101(1):217-26

Nimodipine has an inhibitory action on neurotransmitter release from human cerebral arteries. Porter ID, et al. **J Cereb Blood Flow Metab** 1985 Jun;5(2):338-42

Determination of choline and acetylcholine levels in rat brain regions by liquid chromatography with electrochemical detection. Ikarashi Y, et al. **J Chromatogr** 1985 Mar 29;322(1):191-9

Chromatographic analysis of choline and acetylcholine by UV visualization. Jones RS, et al. **J Chromatogr** 1985 Feb 20; 319(3):454-60

Modulation of the acetylcholine system in the superior cervical ganglion of rat: effects of GABA and hypoglossal nerve implantation after in vivo GABA treatment. Kása P, et al. **J Neurochem** 1985 May; 44(5):1363-72

Newly synthesized and preformed acetylcholine are released from Torpedo synaptosomes by different pathways. Luz S, et al. **J Neurochem** 1985 Jul;45(1):43-50

Changes in presynaptic release of acetylcholine during development of tolerance to the anticholinesterase, DFP. Russell RW, et al. **J Neurochem** 1985 Jul;45(1):293-9

High-affinity binding of [3H]acetylcholine to muscarinic cholinergic receptors. Kellar KJ, et al. **J Neurosci** 1985 Jun;5(6):1577-82

Pharmacological and ionic characterizations of the muscarinic receptors modulating [3H]acetylcholine release from rat cortical synaptosomes. Meyer EM, et al. **J Neurosci** 1985 May;5(5):1202-7

Bombesin evoked acetylcholine release from the guinea pig antrum. Kantoh M, et al. **Life Sci** 1985 Jun 24;36(25):2445-52

Oxidative metabolism and acetylcholine synthesis during acetylpyridine treatment. Gibson GE, et al. **Neurochem Res** 1985 Apr;10(4):453-67

The compartmentalized hypothalamo-neurohypophysial system: evidence for a neurohypophysial action of acetylcholine on vasopressin release. Gregg CM. **Neuroendocrinology** 1985 May;40(5):423-9

The modulation of cortical acetylcholine release by GABA, GABA-like drugs and benzodiazepines in freely moving guinea-pigs. Tanganelli S, et al. **Neuropharmacology** 1985 Apr;24(4):291-9

State of adrenergic and cholinergic systems in schizophrenia patients during psychopharmacotherapy. Krupenina LB, et al. **Neurosci Behav Physiol** 1985 Jan-Feb;15(1):1-8

Acetylcholine-induced currents at plasma membrane of the frog oocyte. Toselli M, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):179-84

Acetylcholine stimulates a Ca2+-dependent C1- conductance in mouse lacrimal acinar cells. Findlay I, et al. **Pflugers Arch** 1985 Mar; 403(3):328-30

The biophysical pharmacology of calcium-dependent acetylcholine secretion. Silinsky EM. **Pharmacol Rev** 1985 Mar;37(1):81-132 (282 ref.)

Neurochemical basis for the photic control of circadian rhythms and seasonal reproductive cycles: role for acetylcholine. Earnest DJ, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(12):4277-81

Is an acetylcholine transport system responsible for nonquantal release of acetylcholine at the rodent myoneural junction? Edwards C, et al. **Proc Natl Acad Sci USA** 1985 May;82(10):3514-8

Chronotropic effects of the reversed carboxyl (RC) analogue of acetylcholine (beta-homobetaine methylester) at defined intraluminal pressures on isolated right rabbit atria. Rossberg F, et al. **Res Exp Med (Berl)** 1985;185(2):139-44

Effects of secretagogues on membrane potential and input resistance of pancreatic acinar cells of sheep. Katoh K, et al. **Res Vet Sci** 1985 Mar; 38(2):250-1

Inhibitory effects of dopamine and isoprenaline on antral motor activity stimulated by acetylcholine or physostigmine in vitro. Ulvestad A, et al. **Scand J Gastroenterol** 1985 Mar;20(2):243-6

The release of acetylcholine. Dunant Y, et al. **Sci Am** 1985 Apr; 252(4):58-66

Immunocytochemical detection of acetylcholine in the rat central nervous system. Geffard M, et al. **Science** 1985 Jul 5;229(4708):77-9

[Relationship between cholinesterase activity and acetylcholine of the brains of mice acutely intoxicated with soman] Zhang X, et al. **Chung Kuo Yao Li Hsueh Pao** 1985 Mar;6(1):16-9 (Eng. Abstr.) **(Chi)**

[Regulation of the cell cycle of B-lymphocytes in mice by substances elevating the levels of intracellular cAMP and cGMP] Ado AD, et al. **Biull Eksp Biol Med** 1985 Apr;99(4):455-8 (Eng. Abstr.) **(Rus)**

[Changes in the response to the extracellular application of acetylcholine during the intracellular perfusion of isolated neurons with biogenic amines] Turpaev TM, et al. **Dokl Akad Nauk SSSR** 1985; 280(6):1495-8 **(Rus)**

[Effect of RNAse inhibitors and activators on acetylcholine interaction with the cholinoreceptor in a tissue extract] Turpaev TM, et al. **Dokl Akad Nauk SSSR** 1985;281(2):500-2 **(Rus)**

[Catecholamine levels in pancreatic tissue after intraperitoneal administration of acetylcholine] Gal'kiv MA, et al. **Fiziol Zh** 1985 Mar-Apr;31(2):230-4 **(Rus)**

[The effect of acetylcholine and histamine on blood flow through the abdominal organs] Antal J, et al. **Bratisl Lek Listy** 1985 Mar; 83(3):218-28 (Eng. Abstr.) **(Slo)**

ACHIEVEMENT

Methylphenidate in hyperactive children: differential effects of dose on academic, learning, and social behavior. Rapport MD, et al. **J Abnorm Child Psychol** 1985 Jun;13(2):227-43

AFFECTIVE DISORDERS

Treatment of affective disorders. Lader MH. **Br J Clin Pharmacol** 1985; 19 Suppl 1:29S-30S

The relationship between antisocial behavior and affective illness. Reich J. **Compr Psychiatry** 1985 May-Jun;26(3):296-303 (47 ref.)

Consensus development summaries. Mood disorders: pharmacologic prevention of recurrences. National Institutes of Health. **Conn Med** 1985 Mar;49(3):157-63

Compliance with outpatient lithium therapy. Connelly CE. **Perspect Psychiatr Care** 1984 Apr-Jun;22(2):44-50

AFFECTIVE DISORDERS, PSYCHOTIC

Mood disorders: pharmacologic prevention of recurrences. National Institutes of Health Consensus Development Conference Statement. **Nat Inst Health Consensus Dev Conf Consensus Statement** 1984; 5(4):8 p.

AFFECTIVE SYMPTOMS

Nomifensine for 'emotional incontinence' of the pseudobulbar type [letter] Sandyk R. **J Am Geriatr Soc** 1985 May;33(5):375

AGGRESSION

Treatment of an aggressive, compulsive adolescent with sultopride [letter] Bucci L. **Am J Psychiatry** 1985 Jul;142(7):882-3

Differential effects of electroconvulsive shock on four models of experimentally-induced aggression in rats. Liou SY, et al. **Jpn J Pharmacol** 1985 Feb;37(2):167-72

Effects of chronic LiCl and RbCl on muricide induced by midbrain raphe lesions in rats. Yamamoto T, et al. **Pharmacol Biochem Behav** 1985 Apr; 22(4):559-63

Target biting associated with a gustatory avoidance response. Wagner GC, et al. **Physiol Behav** 1985 Mar;34(3):465-9

Serotonergic control of experimental aggression. Valzelli L, et al. **Pol J Pharmacol Pharm** 1984 Sep-Oct;36(5):495-503

Biogenic amine alterations in limbic brain regions of muricidal rats. Broderick PA, et al. **Res Commun Chem Pathol Pharmacol** 1985 Apr; 48(1):3-15

AMINO ACIDS

Effects of jejunoileal bypass on food intake, amino acid levels, and indoleamine metabolism in rats. Herlin PM, et al. **Am J Surg** 1985 Jun; 149(6):739-44

Synthesis of side chain-protected amino acid phenylthiohydantoins and their use in quantitative solid-phase Edman degradation. Steiman DM, et al. **Anal Biochem** 1985 Feb 15;145(1):91-5

Effects of diazinon on nucleotide and amino acid contents of chick embryos. Teratogenic considerations. Kushaba-Rugaaju S, et al. **Biochem Pharmacol** 1985 Jun 1;34(11):1937-43

Aromatic amino acid metabolites as potential protein binding inhibitors in human uremic plasma. Tavares-Almeida I, et al. **Biochem Pharmacol** 1985 Jul 15;34(14):2431-8

Determination of the relative positions of amino acids by partial specific cleavages of end-labeled proteins. Jue RA, et al. **Biochemistry** 1985 Jan 1;24(1):162-70

Antagonism of inhibitory amino acids by the steroid derivative RU5135. Simmonds MA, et al. **Br J Pharmacol** 1985 Mar;84(3):631-5

Quantitative review of optimum amino acid intakes for young laying pullets. McDonald MW, et al. **Br Poult Sci** 1985 Apr;26(2):253-64 (32 ref.)

Effects of excitatory amino acids on calcium transport by brain membranes. Harris RA. **Brain Res** 1985 Jun 24;337(1):167-70

Modulatory effects of prostaglandin D2, E2 and F2 alpha on the postsynaptic actions of inhibitory and excitatory amino acids in cerebellar Purkinje cell dendrites in vitro. Kimura H, et al. **Brain Res** 1985 Mar 25;330(2):235-44

Isocratic separation of PTH-amino acids at picomole level by reverse-phase HPLC in the presence of sodium dodecylsulfate. Tsunasawa S, et al. **J Biochem (Tokyo)** 1985 Feb;97(2):701-4

Determination of neurotransmitter amino acids by high-performance liquid chromatography with fluorescence detection. Zecca L, et al. **J Chromatogr** 1985 Feb 8;337(2):391-6

An artifact in urinary amino acid analysis produced by tris(hydroxymethyl)aminomethane (THAM). Wilson WG, et al. **J Inherited Metab Dis** 1985;8(1):24

Orally active and potent inhibitors of gamma-aminobutyric acid uptake. Ali FE, et al. **J Med Chem** 1985 May;28(5):653-60

Synthesis and structure-activity studies on excitatory amino acids structurally related to ibotenic acid. Krogsgaard-Larsen P, et al. **J Med Chem** 1985 May;28(5):673-9

Ibotenic acid analogues. Synthesis, molecular flexibility, and in vitro activity of agonists and antagonists at central glutamic acid receptors. Lauridsen J, et al. **J Med Chem** 1985 May;28(5):668-72

An excitant amino acid projection from the medial prefrontal cortex to the anterior part of nucleus accumbens in the rat. Christie MJ, et al. **J Neurochem** 1985 Aug;45(2):477-82

Potassium-induced release of endogenous amino acids in the guinea pig cochlea. Jenison GL, et al. **J Neurochem** 1985 Jun;44(6):1845-53

Afferent facilitation induced by iontophoretic application of acidic amino acids in the ampullary electroreceptors of Plotosus. Nagai T, et al. **J Neurophysiol** 1985 Apr;53(4):853-67

Pharmacological characterization of postsynaptic receptors for excitatory amino acids in Purkinje cell dendrites in the guinea pig cerebellum. Kimura H, et al. **J Pharmacobiodyn** 1985 Feb;8(2):119–27

Release of endogenous dopamine, 3,4–dihydroxyphenylacetic acid, and amino acid transmitters from rat striatal slices. Flint RS, et al. **Neurochem Res** 1985 Apr;10(4):515–27

Transport of monoamine and amino acid neurotransmitters by primary astroglial cultures. Hansson E. **Neurochem Res** 1985 May; 10(5):667–75

Glutamine–induced alterations in the content of brain amino acid neurotransmitters in rats with different alcohol motivation. Ostrovsky SYu. **Subst Alcohol Actions Misuse** 1984;5(5):247–53

Electrophysiological studies on neuronal transmission in the frog's photosensory pineal organ. The effect of amino acids and biogenic amines. Meissl H, et al. **Vision Res** 1984;24(12):1727–34

[Observations on the use of amino–acid mixtures in severe burn patients] Wang QF, et al. **Chung Hua Wai Ko Tsa Chih** 1985 Feb; 23(2):69–71, 125 (Eng. Abstr.) **(Chi)**

[Biochemistry of the brain. b. Amino acids, polypeptides, and proteins] Nishimura T, et al. **Nippon Rinsho** 1985 Feb;43(2):253–7 (30 ref.) **(Jpn)**

[Differential spectrophotometry of iodinated proteins and amino acids in heavy water] Gussakovskii EE, et al. **Biofizika** 1985 Mar–Apr; 30(2):208–10 (Eng. Abstr.) **(Rus)**

AMITRIPTYLINE

Chlordiazepoxide toxicity in Limbitrol overdose [letter] Goethe JW, et al. **Am J Psychiatry** 1985 Jun;142(6):774

Comparison of the effects of binodaline and amitriptyline on peripheral autonomic functions in healthy volunteers. Longmore J, et al. **Br J Clin Pharmacol** 1985 Mar;19(3):295–300

A comparison of the cardiovascular effects and subjective tolerability of binedaline and amitriptylene in healthy volunteers. Joubert PH, et al. **Eur J Clin Pharmacol** 1985;27(6):667–70

Why is amitriptyline much weaker than desipramine at decreasing beta–adrenoceptor numbers? Wise H, et al. **Eur J Pharmacol** 1985 Mar 26;110(1):137–41

Tricyclic antidepressants antagonize prostaglandin (PG) E2–induced contractions of the guinea pig ileum and hypomotility in the mouse. Tayo FM. **Experientia** 1985 Apr 15;41(4):474–6

Determination of cyclobenzaprine in plasma and urine using capillary gas chromatography with nitrogen–selective detection. Constanzer ML, et al. **J Chromatogr** 1985 May 3;339(2):414–8

Plasma levels of amitriptyline: effect of age and sex. Preskorn SH, et al. **J Clin Psychiatry** 1985 Jul;46(7):276–7

Amitriptyline and contact lenses [letter] Troiano G. **J Clin Psychiatry** 1985 May;46(5):199

Amitriptyline and hydroxylated metabolite plasma levels in depressed outpatients. Robinson DS, et al. **J Clin Psychopharmacol** 1985 Apr; 5(2):83–8

Comparison of limbitrol (chlordiazepoxide/amitriptyline) and amitriptyline alone as a single night–time dose for the treatment of depression with anxiety. James RT, et al. **J Int Med Res** 1985; 13(2):84–7

Inhibition of the retrograde axonal transport of acetylcholinesterase by the anti–calmodulin agents amitriptyline and desipramine. Tiberi M, et al. **J Neurobiol** 1985 May;16(3):245–8

Responsibilities of prescribing. Avery JK. **J Tenn Med Assoc** 1985 May; 78(5):297

Effects of acute and chronic treatment with amitryptyline on the sleep–wake activity of rats. Obál F Jr, et al. **Neuropharmacology** 1985 Mar;24(3):223–9

Mianserin versus amitriptyline for depression: a double–blind 6–week trial. Rabkin JG, et al. **Neuropsychobiology** 1984;12(4):224–8

AMOBARBITAL

[Attempted suicide with barbiturate after glue sniffing] Sami HO, et al. **Orv Hetil** 1985 Mar 31;126(13):781–3 (Eng. Abstr.) **(Hun)**

[Barbamyl distribution in human blood] Kudrin AN, et al. **Farmakol Toksikol** 1985 Mar–Apr;48(2):113–5 (Eng. Abstr.) **(Rus)**

AMPHETAMINE

Pre–school children of amphetamine–addicted mothers. II. Environment and supportive social welfare. Eriksson M, et al. **Acta Paediatr Scand** 1985 Mar;74(2):185–90

Differential response to amphetamine in schizophrenia. Cesarec Z, et al. **Acta Psychiatr Scand** 1985 May;71(5):523–38

Effects of D– and L–amphetamine on dopamine metabolism and ascorbic acid levels in nucleus accumbens and olfactory tubercle as studied by in vivo differential pulse voltammetry. Louilot A, et al. **Brain Res** 1985 Jun 17;336(2):253–63

Single–reagent polarization fluoroimmunoassay for amphetamine in urine. Colbert DL, et al. **Clin Chem** 1985 Jul;31(7):1193–5

Opposite effects of sulpiride and metoclopramide on amphetamine–induced stereotypy. Robertson A, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):81–9

Liquid chromatographic determination of the enantiomeric composition of amphetamine and related drugs by diastereomeric derivatization. Barksdale JM, et al. **J Chromatogr Sci** 1985 Apr;23(4):176–80

Reserpine–induced hypothermia and its reversal by dopamine agonists. Danielson TJ, et al. **Life Sci** 1985 Jul 8;37(1):31–8

Norepinephrine–dependent and independent mechanisms of persistent effects of amphetamine in rat cerebellum. Sorensen SM, et al. **Life Sci** 1985 Jun 24;36(25):2383–9

Hypothalamic involvement in the locomotor stimulant or satiety action of thyrotropin–releasing hormone and amphetamine. Shian LR, et al. **Pharmacology** 1985;30(5):259–65

Development of mouse activity, stimulus reactivity, habituation, and response to amphetamine and scopolamine. Alleva E, et al. **Physiol Behav** 1985 Apr;34(4):519–23

Amphetamine response and relapse risk after depot neuroleptic discontinuation. Angrist B, et al. **Psychopharmacology (Berlin)** 1985; 85(3):277–83

Specific opioid–amphetamine interactions in the caudate putamen. Woo SK, et al. **Psychopharmacology (Berlin)** 1985;85(3):371–6

The effect of previous d–amphetamine treatment on the disposition and lethality of fenfluramine in the rat. Hunsinger RN, et al. **Toxicol Appl Pharmacol** 1985 Jun 30;79(2):236–45

[Comparative effect of the psychostimulants sidnocarb and fenamin on the tyrosine hydroxylase activity of the brain synaptosomes in rats] Ganiev MM, et al. **Farmakol Toksikol** 1985 Mar–Apr;48(2):27–32 (Eng. Abstr.) **(Rus)**

[Effect of stable strontium on spontaneous and drug–induced motor activity in the rat] Escanero JF, et al. **Arch Farmacol Toxicol** 1985 Apr; 11(1):33–9 (Eng. Abstr.) **(Spa)**

[Is the combination of amphetamine and chloroquine the cause of unexpected psychological symptoms?] **Lakartidningen** 1985 May 22; 82(21):1962 **(Swe)**

AMPHETAMINES

4–Bromo–2,5–dimethoxyphenethylamine: identification of a new street drug. Ragan FA Jr, et al. **J Anal Toxicol** 1985 Mar–Apr;9(2):91–3

Board of Medicine proposes new amphetamine rules. **Mich Med** 1985 Feb;84(2):100–2

Psychobiological foundations of behaviors induced by amphetamines. Groves PM, et al. **Natl Inst Drug Abuse Res Monogr Ser** 1984; 54:356–66

p–Chloroamphetamine: effect on sleep and respiration in the rat. DeMesquita S. **Pharmacol Biochem Behav** 1985 May;22(5):889–91

Structure–activity studies on methoxy–substituted phenylisopropylamines using drug discrimination methodology. Glennon RA, et al. **Pharmacol Biochem Behav** 1985 May;22(5):723–9

[Microanalysis of amphetamines III. Detection of amphetamines in the hair of monkeys treated with methamphetamine] Takahashi K, et al. **Eisei Shikenjo Hokoku** 1984;(102):21–4 (Eng. Abstr.) **(Jpn)**

ANOREXIA NERVOSA

Chlorpromazine–associated haemolysis in anorexia nervosa. Van der Weyden MB, et al. **Acta Haematol (Basel)** 1985;73(2):111–3

Activity measures in anorexia nervosa. Falk JR, et al. **Arch Gen Psychiatry** 1985 Aug;42(8):811–4

Anorexia nervosa: aetiological theories and treatment methods. Bryant R, et al. **J Adolesc** 1985 Mar;8(1):93–103

Behavior therapy, pimozide treatment and prolactin secretion in anorexia nervosa. Weizman A, et al. **Psychother Psychosom** 1985;43(3):136–40

ANTIDEPRESSIVE AGENTS

1st Czechoslovak Conference on Biological Psychiatry. Karlovy Vary (Karlsbad), September 1983. Abstracts. **Act Nerv Super (Praha)** 1985 Mar;27(1):60–72

Alteration of histamine metabolism in the rat brain under influence of various antidepressive treatments. Zawilska J, et al. **Agents Actions** 1985 Apr;16(3–4):105–8

Qualitative and quantitative analysis of the action of typical and atypical antidepressants in the experimental animal. Kozlovskaya MM, et al. **Ann Ist Super Sanita** 1984;20(1):73–7

Effects of long–term drug treatments on the sensitivity of presynaptic receptors regulating neurotransmitter release. Raiteri M, et al. **Ann Ist Super Sanita** 1984;20(1):57–64

Membrane–related effects of atypical antidepressants. Valdman AV, et al. **Ann Ist Super Sanita** 1984;20(1):65–72

Resting metabolic rate is reduced in patients treated with antidepressants. Fernstrom MH, et al. **Biol Psychiatry** 1985 Jun;20(6):692–5

Comparison of the effects of binodaline and amitriptyline on peripheral autonomic functions in healthy volunteers. Longmore J, et al. **Br J Clin Pharmacol** 1985 Mar;19(3):295–300

Antidepressant properties of the triazolobenzodiazepines alprazolam and adinazolam: studies on the olfactory bulbectomized rat model of depression. O'Connor WT, et al. **Br J Clin Pharmacol** 1985;

19 Suppl 1:49S–56S

A comparison of the cardiovascular effects and subjective tolerability of binedaline and amitriptylene in healthy volunteers. Joubert PH, et al. **Eur J Clin Pharmacol** 1985;27(6):667–70

Interindividual differences in the binding of antidepressives to plasma proteins: the role of the variants of alpha 1-acid glycoprotein. Tinguely D, et al. **Eur J Clin Pharmacol** 1985;27(6):661–6

Evidence of dopamine involvement in the effect of repeated treatment with various antidepressants in the behavioural 'despair' test in rats. Borsini F, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):253–6

Drug response as a predictor of transmission of non-bipolar major depression within families. Prusoff BA, et al. **J Affective Disord** 1985 Mar–Apr;8(2):171–6

1-Azacycloalkyl-1,4-benzodiazepin-2-ones with antianxiety-antidepressant actions. Sugasawa T, et al. **J Med Chem** 1985 Jun;28(6):699–707

Synthesis and antidepressant profiles of phenyl-substituted 2-amino- and 2-[(alkoxycarbonyl)amino]-1,4,5,6-tetrahydropyrimidines. Weinhardt K, et al. **J Med Chem** 1985 Jun;28(6):694–8

Neurochemical profile of Lu 19-005, a potent inhibitor of uptake of dopamine, noradrenaline, and serotonin. Hyttel J, et al. **J Neurochem** 1985 May;44(5):1615–22

5-Hydroxytryptamine-stimulated inositol phospholipid hydrolysis in rat cerebral cortex slices: pharmacological characterization and effects of antidepressants. Kendall DA, et al. **J Pharmacol Exp Ther** 1985 May;233(2):473–9

Effects of clenbuterol and antidepressant drugs on beta adrenergic receptor/N-protein coupling in the cerebral cortex of the rat. O'Donnell JM, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):30–6

Enhanced signal transduction by adenylate cyclase in platelet membranes of patients showing antidepressant responses to alprazolam: preliminary data. Mooney JJ, et al. **J Psychiatr Res** 1985;19(1):65–75

Elevation of mood due to antidepressants [letter] Pearce PL. **JAMA** 1985 Jun 7;253(21):3091–2

On acute and chronic CNS effects of antidepressants in normals: neurophysiological, behavioral and pharmacokinetic studies with pirlindol. Saletu B, et al. **Methods Find Exp Clin Pharmacol** 1985 Mar;7(3):137–51

Antidepressants and endogenous opioid peptide systems. Przewłocki R, et al. **Neuropeptides** 1985 Feb;5(4–6):575–8

Serotonin and antidepressant drugs antagonize melatonin-induced behavioural changes after injection into the nucleus accumbens of rats. Gaffori O, et al. **Neuropharmacology** 1985 Mar;24(3):237–44

Parallel changes in the sensitivity of gamma-aminobutyric acid and noradrenergic receptors following chronic administration of antidepressant and GABAergic drugs. A possible role in affective disorders. Suzdak PD, et al. **Neuropharmacology** 1985 Mar;24(3):217–22

The olfactory bulbectomized rat as a model of depression. Leonard BE. **Pol J Pharmacol Pharm** 1984 Sep–Oct;36(5):561–9 (30 ref.)

Characterization of the bupropion cue in the rat: lack of evidence for a dopaminergic mechanism. Blitzer RD, et al. **Psychopharmacology (Berlin)** 1985;85(2):173–7

The tail suspension test: a new method for screening antidepressants in mice. Steru L, et al. **Psychopharmacology (Berlin)** 1985;85(3):367–70

The activation of mice's behavior and reduction of brain beta-adrenergic receptor binding following repeated administration of antidepressant drugs. Nomura S, et al. **Yakubutsu Seishin Kodo** 1984 Nov;4(3):237–41

[Effect of acute administration of antidepressive agents at 2 P.M. on plasma and pineal levels of melatonin in the rat] Mouren P, et al. **Encephale** 1985 Jan–Feb;11(1):29–30 (Eng. Abstr.) **(Fre)**

[Drug flush. Possible role of indalpine overdosage (letter)] Manigand G, et al. **Presse Med** 1985 Apr 13;14(15):841 **(Fre)**

[Therapeutic strategy in depression] Scotto JC, et al. **Rev Prat** 1985 May 11;35(27):1633–8 (Eng. Abstr.) **(Fre)**

[Treatment of depressive syndrome with antidepressants] Woggon B, et al. **Med Monatsschr Pharm** 1985 May;8(5):130–6 **(Ger)**

[Inhibition of brain monoamine oxidase in the rat by multiple pyrazidol administration] Verevkina IV, et al. **Biull Eksp Biol Med** 1985 May;99(5):583–4 (Eng. Abstr.) **(Rus)**

[Comparative study of the indices of the antidepressive activity of potassium orotate and piracetam] Karkishchenko NN, et al. **Farmakol Toksikol** 1985 Mar–Apr;48(2):32–5 (Eng. Abstr.) **(Rus)**

[The effect of psychopharmacologic agents on the passive transport of Ca2+ induced by vanadate in human erythrocytes] Pogády J, et al. **Bratisl Lek Listy** 1985 Apr;83(4):345–52 (Eng. Abstr.) **(Slo)**

ANTISOCIAL PERSONALITY DISORDER

The relationship between antisocial behavior and affective illness. Reich J. **Compr Psychiatry** 1985 May–Jun;26(3):296–303 (47 ref.)

ANXIETY

A double-blind comparison of alprazolam, diazepam and placebo in the treatment of anxious out-patients. Davison K, et al. **Br J Clin Pharmacol** 1985;19 Suppl 1:37S–43S

A comparison of the effects of lorazepam with those of propranolol on experimentally-induced anxiety and performance. File SE, et al. **Br J Clin Pharmacol** 1985 Apr;19(4):445–51

Brief review of published alprazolam clinical studies. Straw RN. **Br J Clin Pharmacol** 1985;19 Suppl 1:57S–59S (22 ref.)

Controlled study of withdrawal symptoms and rebound anxiety after six week course of diazepam for generalised anxiety. Power KG, et al. **Br Med J [Clin Res]** 1985 Apr 27;290(6477):1246–8

Drugs in dentistry. Agents for anxiety disorders. Ciancio SG. **Dent Manage** 1985 Jun;25(6):66, 68, 70

Animal models for the study of anti-anxiety agents: a review. Treit D. **Neurosci Biobehav Rev** 1985 Summer;9(2):203–22

The effects of compounds related to gamma-aminobutyrate and benzodiazepine receptors on behavioural responses to anxiogenic stimuli in the rat: punished barpressing. Quintero S, et al. **Psychopharmacology (Berlin)** 1985;85(2):244–51

[Clinical trial of the action of a benzodiazepine (Lexotan) on the behavior of the anxious patient in dental outpatient care] Debernardi G, et al. **Minerva Stomatol** 1985 Mar–Apr;34(2):323–8 (Eng. Abstr.) **(Ita)**

[Anxiolytic action of sodium valproate (possible role of gamma-aminobutyric acid in affective disorders)] Raevskii KS, et al. **Zh Nevropatol Psikhiatr** 1985;85(4):574–9 (Eng. Abstr.) **(Rus)**

ANXIETY DISORDERS

Management of specific anxiety disorders in the elderly. Turnbull JM, et al. **Geriatrics** 1985 Aug;40(8):75–82

Emergency treatment of acute psychosis, agitation, and anxiety. Ellison JM. **Hosp Community Psychiatry** 1985 Apr;36(4):351–2

L-5-hydroxytryptophan in the treatment of anxiety disorders. Kahn RS, et al. **J Affective Disord** 1985 Mar–Apr;8(2):197–200

Self-reports of anxiety level and EEG changes after a single dose of benzodiazepines. Double-blind comparison of two forms of oxazepam. Ansseau M, et al. **Neuropsychobiology** 1984;12(4):255–9

Clinical pharmacology of benzodiazepines. Rickels K. **Pharmacopsychiatry** 1985 Jan;18(1):156–9

The anxiolytic activity of beta-carboline derivatives in mice, and its separation from ataxic properties. Stephens DN, et al. **Pharmacopsychiatry** 1985 Jan;18(1):167–70

New findings in anxiety. A synthesis for clinical practice in 1985. Curtis GC. **Psychiatr Clin North Am** 1985 Mar;8(1):169–75

Generalized anxiety disorder. Hoehn-Saric R, et al. **Psychiatr Clin North Am** 1985 Mar;8(1):73–88 (65 ref.)

Imipramine in the treatment of panic disorder and its complications. Liebowitz MR. **Psychiatr Clin North Am** 1985 Mar;8(1):37–47

APOMORPHINE

Effect of metoclopramide, domperidone and apomorphine on GH secretion in children and adolescents. Massara F, et al. **Acta Endocrinol (Copenh)** 1985 Apr;108(4):451–5

Characteristics of yawning behavior induced by apomorphine, physostigmine and pilocarpine. Ushijima I, et al. **Arch Int Pharmacodyn Ther** 1985 Feb;273(2):196–201

Low doses of apomorphine elicit two opposing influences on dopamine cell electrophysiology. Grace AA, et al. **Brain Res** 1985 May 6;333(2):285–98

Antagonism of apomorphine-enhanced startle by alpha 1-adrenergic antagonists. Davis M, et al. **Eur J Pharmacol** 1985 Feb 5;108(3):233–41

Sedation and sleep induced by high doses of apomorphine after blockade of D-1 receptors by SCH 23390. Gessa GL, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):269–74

Effect of the dopamine D-1 antagonist SCH 23390 on rotational behaviour induced by apomorphine and pergolide in 6-hydroxy-dopamine denervated rats. Herrera-Marschitz M, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):349–54

Sniffing, rearing and locomotor responses to the D-1 dopamine agonist R-SK&F 38393 and to apomorphine: differential interactions with the selective D-1 and D-2 antagonists SCH 23390 and metoclopramide. Molloy AG, et al. **Eur J Pharmacol** 1985 Feb 5;108(3):305–8

The supersensitivity of dopaminergic neurons to apomorphine in rats following chronic haloperidol. Vogelsang GD, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):267–9

Reserpine-induced hypothermia and its reversal by dopamine agonists. Danielson TJ, et al. **Life Sci** 1985 Jul 8;37(1):31–8

Inhibitory effects of apomorphine and pergolide on neurogenic vasoconstriction in the hindquarters of the rat. Dupont AG, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):146–51

Effects of discriminant and non-discriminant dopamine antagonists on in vivo accumulation of 3H-N-propyl-norapomorphine in mouse striatum and tuberculum olfactorium. Gulat-Marnay C, et al.

Naunyn Schmiedebergs Arch Pharmacol 1985 Apr;329(2):117–22

Chlorimipramine, electroconvulsive shock and combination thereof: differential effects of chronic treatment on apomorphine-induced behaviours and on striatal and mesocortical dopamine turnover. Spyraki C, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):128–34

Effect of chronic haloperidol and quinacrine coadministration on striatal HVA levels and stereotypic behaviors in response to apomorphine in the rat. Deutsch SI, et al. **Neurochem Res** 1985 Apr;10(4):491–8

Antistereotypic effects of cholecystokinin octapeptide (CCK-8), ceruletide and related peptides on apomorphine-induced gnawing in sensitized mice. Zetler G. **Neuropharmacology** 1985 Mar;24(3):251–9

In vivo electrochemical monitoring of apomorphine penetration into the rat brain. Marcenac FM, et al. **Neurosci Lett** 1985 Apr 19; 55(3):305–10

The morphogenesis of stereotyped behavior induced by the dopamine receptor agonist apomorphine in the laboratory rat. Szechtman H, et al. **Neuroscience** 1985 Mar;14(3):783–98

Effect of chronic apomorphine on the development of denervation supersensitivity. Robin M, et al. **Pharmacol Biochem Behav** 1985 Apr; 22(4):547–51

Effects of selective dopamine receptor agonists in rats trained to discriminate apomorphine from saline. Woolverton WL, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):577–81

Differential involvement of dopamine D-1 and D-2 receptors in the circling behaviour induced by apomorphine, SK & F 38393, pergolide and LY 171555 in 6-hydroxydopamine-lesioned rats. Arnt J, et al. **Psychopharmacology (Berlin)** 1985;85(3):346–52

Increased or decreased locomotor response in rats following repeated administration of apomorphine depends on dosage interval. Castro R, et al. **Psychopharmacology (Berlin)** 1985;85(3):333–9

Influence of cimetidine, ranitidine and imidazole on the behavioral effects of (+/-) N-n-propylnorapomorphine in male rats. Ferrari F, et al. **Psychopharmacology (Berlin)** 1985;85(2):197–200

Increase in plasma ACTH after dopaminergic stimulation in rats. Ježová D, et al. **Psychopharmacology (Berlin)** 1985;85(2):201–3

Effects of apomorphine and haloperidol on 'spontaneous' stereotyped licking behaviour in the Cebus monkey. Korsgaard S, et al. **Psychopharmacology (Berlin)** 1985;85(2):240–3

A computer-supported method for analyzing behavioral observations: studies with stereotypy. Lewis MH, et al. **Psychopharmacology (Berlin)** 1985;85(2):204–9

Studies on the stability of 3H-dopamine, 3H-apomorphine and 3H-ADTN: effects of sodium ascorbate and EDTA. Cabbat FS, et al. **Res Commun Chem Pathol Pharmacol** 1985 Mar;47(3):333–43

Circadian variation in the ambulation-increasing effect of apomorphine after repeated administration in mice. Kuribara H, et al. **Yakubutsu Seishin Kodo** 1984 Nov;4(3):231–6

APPETITE

d-Fenfluramine and salbutamol: two drugs causing anorexia through different neurochemical mechanisms. Garattini S, et al. **Int J Obes** 1984; 8 Suppl 1:151–7

The clinical pharmacology of appetite suppressant drugs. Silverstone T, et al. **Int J Obes** 1984;8 Suppl 1:23–33

AROUSAL

Are the anxiogenic effects of yohimbine mediated by its action at benzodiazepine receptors? Pellow S, et al. **Neurosci Lett** 1985 Mar 22; 55(1):5–9

Clinical pharmacology of benzodiazepines. Rickels K. **Pharmacopsychiatry** 1985 Jan;18(1):156–9

1,2-Anellated 1,4-benzodiazepine derivatives--a new class of antipsychotics. Ruhland M, et al. **Pharmacopsychiatry** 1985 Jan; 18(1):174–7

The anxiolytic activity of beta-carboline derivatives in mice, and its separation from ataxic properties. Stephens DN, et al. **Pharmacopsychiatry** 1985 Jan;18(1):167–70

Paradoxical sleep deprivation and the immobility response in the rat: effects of desipramine and phentolamine. van Luijtelaar EL, et al. **Sleep** 1985;8(1):49–55

Behavioural and endocrine reactions in boys scoring high on Sennton neurotic scale viewing an exciting and partly violent movie and the importance of social support. Arnetz BB, et al. **Soc Sci Med** 1985; 20(7):731–6

ATTENTION

Noradrenergic modulation of selective attention: its role in memory retrieval. Sara SJ. **Ann NY Acad Sci** 1985;444:178–93

A limiting factor in the 'normalization' of schizophrenic orienting response dysfunction. Bernstein AS, et al. **Schizophr Bull** 1985;11(2):230–54

ATTENTION DEFICIT DISORDER WITH HYPERACTIVITY

Evaluating drug effectiveness in an office setting for children with attention deficit disorders. Ottinger DR, et al. **Clin Pediatr (Phila)** 1985 May;24(5):245–51

Oral pemoline kinetics in hyperactive children. Sallee F, et al. **Clin Pharmacol Ther** 1985 Jun;37(6):606–9

Methylphenidate in hyperactive children: differential effects of dose on academic, learning, and social behavior. Rapport MD, et al. **J Abnorm Child Psychol** 1985 Jun;13(2):227–43

Stimulants and neuroleptics in hyperactive children [letter] Gualtieri CT, et al. **J Am Acad Child Psychiatry** 1985 May;24(3):363–4

Cardiovascular effects of desipramine in children and adolescents with attention deficit disorder. Biederman J, et al. **J Pediatr** 1985 Jun; 106(6):1017–20

Adolescent outcome of hyperactive children treated with stimulants in childhood: a review. Hechtman L. **Psychopharmacol Bull** 1985; 21(2):178–91 (15 ref.)

New drug trials in attention deficit disorder. Rapoport JL, et al. **Psychopharmacol Bull** 1985;21(2):232–6 (16 ref.)

A review of studies of drug treatment efficacy for attention deficit disorder with hyperactivity in adolescents. Varley CK. **Psychopharmacol Bull** 1985;21(2):216–21 (31 ref.)

Pharmacological treatment of attention deficit disorder, residual type (ADD,RT, 'minimal brain dysfunction,' 'hyperactivity') in adults. Wender PH, et al. **Psychopharmacol Bull** 1985;21(2):222–31

Methylphenidate: rate-dependent drug effects in hyperactive boys. Weber K. **Psychopharmacology (Berlin)** 1985;85(2):231–5

[Urinary 3-methoxy-4-hydroxyphenylglycol sulfate in school children with minimal brain dysfunction syndrome] Wang YF. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1985 Feb; 18(1):45–9 (Eng. Abstr.) **(Chi)**

AUTISM, INFANTILE

Vitamin B6, magnesium, and combined B6-Mg: therapeutic effects in childhood autism. Martineau J, et al. **Biol Psychiatry** 1985 May; 20(5):467–78

Serotonin relationships of autistic probands and their first-degree relatives. Kuperman S, et al. **J Am Acad Child Psychiatry** 1985 Mar; 24(2):186–90

AVOIDANCE LEARNING

Direct and indirect behavioral pathways to the social transmission of food avoidance. Galef BG Jr. **Ann NY Acad Sci** 1985;443:203–15

Introduction: physiological mechanisms in conditioned taste aversions. Grill HJ. **Ann NY Acad Sci** 1985;443:67–88

Conditioned food aversions and satiety signals. Kulkosky PJ. **Ann NY Acad Sci** 1985;443:330–47

Conditioned taste aversions: a behavioral index of toxicity. Riley AL, et al. **Ann NY Acad Sci** 1985;443:272–92

Glucocorticoid and other hormonal substrates of conditioned taste aversion. Smotherman WP. **Ann NY Acad Sci** 1985;443:126–44

Interfering with taste aversion learning in rats: the role of associative interference. Cannon DS, et al. **Appetite** 1985 Mar;6(1):1–19

Effects of tifluadom on passive avoidance behaviour in DBA/2 mice. Pavone F, et al. **Behav Brain Res** 1985 May;15(3):177–81

Response of the rat brain beta-endorphin system to novelty: importance of the fornix connection. Netto CA, et al. **Behav Neural Biol** 1985 Jan; 43(1):37–46

Central versus peripheral actions of Leu-enkephalin on acquisition of a one-way active avoidance response in rats. Martinez JL Jr, et al. **Brain Res** 1985 Feb 18;327(1–2):37–43

Aversive effects of subcutaneously injected vasopressin in the rat: independence of the ascending dorsal noradrenergic bundle. Tam FW, et al. **Brain Res** 1985 Jun 24;337(1):133–7

Spontaneous configuring in conditioned flavor aversion. Forbes DT, et al. **J Exp Psychol [Anim Behav]** 1985 Apr;11(2):224–40

Potentiation and overshadowing in preweanling and adult rats. Kucharski D, et al. **J Exp Psychol [Anim Behav]** 1985 Jan;11(1):15–34

2-Amino-4-phosphonobutyric acid selectively blocks two-way avoidance learning in the mouse. Sahai S, et al. **Neurosci Lett** 1985 May 14; 56(2):137–42

Dose-related effects of pentobarbital on the genetic differences seen between paired, Roman high- or low-avoidance rats in a shuttle box. Driscoll P, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):435–9

Effects of psychotropic drugs on discrimination conditioning in olfactory bulbectomized rats. Gomita Y, et al. **Pharmacol Biochem Behav** 1985 May;22(5):717–22

Lithium effects on position learning with exploratory and aversive goal-box conditions. Hines G. **Pharmacol Biochem Behav** 1985 May; 22(5):695–8

Intracortical glutamate injection produces helpless-like behavior in the rat. Petty F, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):531–3

Passive avoidance after ibotenic acid and radio frequency lesions in the rat amygdala. Jellestad FK, et al. **Physiol Behav** 1985 Feb; 34(2):299–305

Conditioned taste aversion suppresses induction of delayed–type hypersensitivity immune reactions. Kelley KW, et al. **Physiol Behav** 1985 Feb;34(2):189–93

Target biting associated with a gustatory avoidance response. Wagner GC, et al. **Physiol Behav** 1985 Mar;34(3):465–9

Luteinizing–hormone–releasing hormone modifies retention of passive and active avoidance responses in rats. Mora S, et al. **Psychopharmacology (Berlin)** 1985;85(3):315–8

Anti–aversive role of serotonin in the dorsal periaqueductal grey matter. Schütz MT, et al. **Psychopharmacology (Berlin)** 1985;85(3):340–5

[3,6–disubstituted 1–lupinylquinoxalin–2(1H)–ones of pharmacological interest. Effect on acquisition and modification of a conditioned avoidance response in rats] Sparatore A, et al. **Farmaco [Sci]** 1985 May; 40(5):303–14 (Eng. Abstr.) **(Ita)**

AZEPINES

Differential modulation of gamma–aminobutyric acid receptors by caprolactam derivatives with central nervous system depressant or convulsant activity. Skerritt JH, et al. **Brain Res** 1985 Apr 8; 331(2):225–33

Pharmacological and neurochemical properties of 1,4–diazepines with two annelated heterocycles ('hetrazepines'). Weber KH, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):19–31

The dopamine autoreceptor agonist B–HT 920 markedly stimulates sexual behavior in male rats. Ferrari F, et al. **Experientia** 1985 May 15; 41(5):636–8

I.R. and N.M.R. spectroscopic studies of 1,4–thienodiazepinic drugs. Fernández–Arciniega MA, et al. **Farmaco [Prat]** 1985 Apr; 40(4):124–30

Synthesis and interaction of 5–(substituted–phenyl)–3–methyl–6,7–dihydropyrazolo[4,3–e][1,4]diazepin–8(7H)–ones with benzodiazepine receptors in rat cerebral cortex. Baraldi PG, et al. **J Med Chem** 1985 May;28(5):683–5

The putative dopamine autoreceptor agonist B–HT 920 decreases nigral dopamine cell firing rate and prolactin release in rat. Eriksson E, et al. **Life Sci** 1985 May 13;36(19):1819–27

Effect of cetiedil on platelet aggregation and thromboxane synthesis. Yamaguchi A, et al. **Thromb Res** 1985 Feb 1;37(3):391–400

[Thin–layer densitometric determination of clotiazepam in tablets and blood plasma] Busch M, et al. **Arzneimittelforsch** 1985;35(2):547–51 (Eng. Abstr.) **(Ger)**

[The effect of dilazep on red cell survival] Saito H, et al. **Rinsho Ketsueki** 1985 Jan;26(1):15–9 (Eng. Abstr.) **(Jpn)**

[New derivatives of 7– and 8–member perhydrocyclic compounds. II. Studies on the effect on the central nervous system and circulatory system of new derivatives of perhydro–1,4–oxazepine, perhydro–1,4–diazepine, perhydro–1,4,5–oxadiazepine and perhydro–1,5–oxazocine containing the 2–guanidinoethyl group] Szadowska A, et al. **Acta Pol Pharm** 1985;42(1):55–60 (Eng. Abstr.) **(Pol)**

BEHAVIOR

Neuropharmacologic management of behavior sequelae in head injury: a case report. Haas JF, et al. **Arch Phys Med Rehabil** 1985 Jul; 66(7):472–4

No acute behavioural effects of exposure to styrene: a safe level of exposure? Edling C, et al. **Br J Ind Med** 1985 May;42(5):301–4

On acute and chronic CNS effects of antidepressants in normals: neurophysiological, behavioral and pharmacokinetic studies with pirlindol. Saletu B, et al. **Methods Find Exp Clin Pharmacol** 1985 Mar; 7(3):137–51

[Clinical trial of the action of a benzodiazepine (Lexotan) on the behavior of the anxious patient in dental outpatient care] Debernardi G, et al. **Minerva Stomatol** 1985 Mar–Apr;34(2):323–8 (Eng. Abstr.) **(Ita)**

BEHAVIOR, ANIMAL

The effects of aniracetam on primate behavior and EEG. Schwam E, et al. **Ann NY Acad Sci** 1985;444:482–4

Characteristics of yawning behavior induced by apomorphine, physostigmine and pilocarpine. Ushijima I, et al. **Arch Int Pharmacodyn Ther** 1985 Feb;273(2):196–201

Some behavioral effects of early styrene intoxication in experimental animals. Husain R, et al. **Arch Toxicol** 1985 Apr;57(1):53–5

Catecholamine–blocking drugs injected at sites of amine accumulation reverse catecholamine degeneration associated deficits. Willis GL, et al. **Behav Brain Res** 1985 Apr;15(2):101–6

Ethanol preference behaviour and dopamine release in the rat. Schmidt J, et al. **Biomed Biochim Acta** 1984;43(12):1431–4

A behavioural and biochemical study in mice and rats of putative selective agonists and antagonists for 5–HT1 and 5–HT2 receptors. Goodwin GM, et al. **Br J Pharmacol** 1985 Mar;84(3):743–53

Involvement of nigrostriatal dopamine neurons in the contraversive rotational behavior evoked by electrical stimulation of the lateral hypothalamus. Castañeda E, et al. **Brain Res** 1985 Feb 18; 327(1–2):143–51

Enhancement of some 5–HT–dependent behavioural responses following repeated immobilization in rats. Kennett GA, et al. **Brain Res** 1985 Mar 25;330(2):253–63

Amine accumulation in behavioural pathology. Willis GL, et al. **Brain Res** 1985 Jun;356(2):109–32 (302 ref.)

Evidence of dopamine involvement in the effect of repeated treatment with various antidepressants in the behavioural 'despair' test in rats. Borsini F, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):253–6

Long–term behavioral effects of phenobarbital in suckling rats. McBride MC, et al. **Exp Neurol** 1985 Jul;89(1):59–70

Behavioral indications for phenothiazine and benzodiazepine tranquilizers in dogs. Hart BL. **J Am Vet Med Assoc** 1985 Jun 1;186(11):1192–4

Effect of immune complex–forming reactants on catecholamine–modulated behaviors in the rat hypothalamus. Schupf N, et al. **J Neuroimmunol** 1985 Jul;9(1–2):13–27

Characteristics of the cortical and hippocampal EEG power spectra of rabbits during normal behavioral states and after administration of CNS acting drugs. Yamamoto J. **Jpn J Pharmacol** 1985 Mar;37(3):227–34

Effects of bombesin on behavior. Cowan A, et al. **Life Sci** 1985 Jul 15; 37(2):135–45

Beta–endorphin–(10–16) antagonizes behavioral responses elicited by melatonin following injection into the nucleus accumbens of rats. Gaffori O, et al. **Life Sci** 1985 Jul 29;37(4):357–64

Development of selective tolerance to the serotonin behavioral syndrome and suppression of locomotor activity after repeated administration of either 5–MeODMT or mCPP. Sills MA, et al. **Life Sci** 1985 Jul 1; 36(26):2463–9

Catecholamine–independent behavioral and neurochemical effects of cocaine in rats. Gale K. **Natl Inst Drug Abuse Res Monogr Ser** 1984; 54:323–32

Psychobiological foundations of behaviors induced by amphetamines. Groves PM, et al. **Natl Inst Drug Abuse Res Monogr Ser** 1984; 54:356–66

The continuity of dopamine receptor antagonism can dictate the long–term behavioural consequences of a mesolimbic infusion of dopamine. Costall B, et al. **Neuropharmacology** 1985 Mar;24(3):193–7

Serotonin and antidepressant drugs antagonize melatonin–induced behavioural changes after injection into the nucleus accumbens of rats. Gaffori O, et al. **Neuropharmacology** 1985 Mar;24(3):237–44

Effects of MET–ENK, substance P and SRIF on the behavior of Hemichromis bimaculatus. Christ H. **Peptides (Fayetteville)** 1985 Jan–Feb;6(1):139–48

Specificity of nucleus accumbens to activities related to cholecystokinin in rats. Katsuura G, et al. **Peptides (Fayetteville)** 1985 Jan–Feb; 6(1):91–6

Altered responses to serotonergic agents in Fawn–Hooded rats. Gudelsky GA, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):489–92

Comparative behavioral effects of CNS cholinesterase inhibitors. Mos DE, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):479–82

Opiomelanocortins and behavioral adaptation. Bohus B. **Pharmacol Ther** 1984;26(3):417–51 (238 ref.)

1.2–Anellated 1.4–benzodiazepine derivatives—a new class of antipsychotics. Ruhland M, et al. **Pharmacopsychiatry** 1985 Jan; 18(1):174–7

Postnatal lead exposure and the cholinergic system. Alfano DP, et al. **Physiol Behav** 1985 Mar;34(3):449–55

8th congress of the Polish Pharmacological Society. Symposium II: Pharmacological implications for animal models of mental disorders. **Pol J Pharmacol Pharm** 1984 Sep–Oct;36(5):493–569

Some behavioral effects of microinjections of serotonin and noradrenaline into the limbic structures of the rat brain. Plaźnik A. **Pol J Pharmacol Pharm** 1984 Sep–Oct;36(5):541–54

Neurotropic drugs and brain development: effects on cell replication in vivo and in vitro. Patel AJ. **Prog Clin Biol Res** 1985;163C:301–5

Influence of cimetidine, ranitidine and imidazole on the behavioral effects of (+/–) N–n–propylnorapomorphine in male rats. Ferrari F, et al. **Psychopharmacology (Berlin)** 1985;85(2):197–200

Effects of some dibenzo–azepines on suppressed and nonsuppressed behavior of squirrel monkeys. Spealman RD. **Psychopharmacology (Berlin)** 1985;85(2):129–32

Chronic neuroleptic treatment and mesolimbic dopamine denervation induce behavioural supersensitivity to opiates. Stinus L, et al. **Psychopharmacology (Berlin)** 1985;85(3):323–8

Specific opioid–amphetamine interactions in the caudate putamen. Woo SK, et al. **Psychopharmacology (Berlin)** 1985;85(3):371–6

Behavioral effects of long–term neuroleptic treatment in Cebus monkeys. Casey DE. **Psychopharmacology [Suppl]** 1985;2:211–6

Functional classification of different dopamine receptors. Ungerstedt U, et al. **Psychopharmacology [Suppl]** 1985;2:19–30

An analysis of some behavioural effects of the vibration and noise components of transport in pigs. Stephens DB, et al. **Q J Exp Physiol** 1985 Apr;70(2):211–7

Biogenic amine alterations in limbic brain regions of muricidal rats. Broderick PA, et al. **Res Commun Chem Pathol Pharmacol** 1985 Apr; 48(1):3-15

[Behavioral pharmacology of amantadine with special references to the effect on abnormal behavior in mice and rats] Fujiwara M, et al. **Nippon Yakurigaku Zasshi** 1985 Apr;85(4):259-74 (Eng. Abstr.) **(Jpn)**

[New derivatives of 7- and 8-member perhydrocyclic compounds. II. Studies on the effect on the central nervous system and circulatory system of new derivatives of perhydro-1,4-oxazepine, perhydro-1,4-diazepine, perhydro-1,4,5-oxadiazepine and perhydro-1,5-oxazocine containing the 2-guanidinoethyl group] Szadowska A, et al. **Acta Pol Pharm** 1985;42(1):55-60 (Eng. Abstr.) **(Pol)**

BENACTYZINE

Comparative effects of aprophen, atropine and benactyzine on central and peripheral cholinoceptors and on acetylcholinesterase. Dawson RM, et al. **Biochem Pharmacol** 1985 May 1;34(9):1577-9

BENZAZEPINES

SCH 23390 may alter dopamine-mediated motor behaviour via striatal D-1 receptors. Boyce S, et al. **Biochem Pharmacol** 1985 May 15; 34(10):1665-9

Inhibition of hepatic microsomal drug metabolism by the calcium channel blockers diltiazem and verapamil. Renton KW. **Biochem Pharmacol** 1985 Jul 15;34(14):2549-53

Hemodynamic and pharmacological effects of the converting enzyme inhibitor CGS 14824A in normal volunteers. Schaller MD, et al. **Eur J Clin Pharmacol** 1985;28(3):267-72

Selective D-1 dopamine receptor increase following chronic treatment with SCH 23390. Creese I, et al. **Eur J Pharmacol** 1985 Feb 12; 109(1):127-8

Sedation and sleep induced by high doses of apomorphine after blockade of D-1 receptors by SCH 23390. Gessa GL, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):269-74

Effect of the dopamine D-1 antagonist SCH 23390 on rotational behaviour induced by apomorphine and pergolide in 6-hydroxy-dopamine denervated rats. Herrera-Marschitz M, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):349-54

Sniffing, rearing and locomotor responses to the D-1 dopamine agonist R-SK&F 38393 and to apomorphine: differential interactions with the selective D-1 and D-2 antagonists SCH 23390 and metoclopramide. Molloy AG, et al. **Eur J Pharmacol** 1985 Feb 5;108(3):305-8

Comparative studies of cardiovascular effects of a new dopamine agonist (SK&F 38393A) and dopamine. Tsai CS, et al. **Gen Pharmacol** 1985; 16(2):85-9

Effects of the calcium antagonist, diltiazem on in vitro and in vivo/in vitro bone resorption. Ly SY, et al. **Horm Metab Res** 1985 Mar; 17(3):152-5

Effects of SK&F 82526 and SK&F 83742 on the renal vascular dopamine receptor. Schmidt M, et al. **J Pharmacol** 1985 Jan-Mar;16(1):15-22

Do D 600 and diltiazem interact with serotonin receptors in rabbit vascular tissues? Ohashi M, et al. **J Pharmacol Exp Ther** 1985 Jun; 233(3):830-5

SCH23390 causes persistent antidopaminergic effects in vivo: evidence for longterm occupation of receptors. Schulz DW, et al. **Life Sci** 1985 May 20;36(20):1941-8

Newer dopamine quinazolones as anti-parkinsonian agents. Kumar P, et al. **Pharmazie** 1985 Apr;40(4):267-8

Differential involvement of dopamine D-1 and D-2 receptors in the circling behaviour induced by apomorphine, SK & F 38393, pergolide and LY 171555 in 6-hydroxydopamine-lesioned rats. Arnt J, et al. **Psychopharmacology (Berlin)** 1985;85(3):346-52

[Effects of diltiazem on plasma ACTH, beta-ELI and ADH levels during surgery] Kono K, et al. **Masui** 1985 Jan;34(1):18-24 (Eng. Abstr.) **(Jpn)**

BENZODIAZEPINE TRANQUILIZERS

Article-induced' dyscontrol [letter] Gardner DL, et al. **Am J Psychiatry** 1985 Jun;142(6):776

The effects of a benzodiazepine antagonist Ro 15-1788 in the presence of stable concentrations of midazolam. Lauven PM. et al. **Anesthesiology** 1985 Jul;63(1):61-4

A double-blind comparison of alprazolam, diazepam and placebo in the treatment of anxious out-patients. Davison K, et al. **Br J Clin Pharmacol** 1985;19 Suppl 1:37S-43S

Pharmacokinetics and pharmacodynamics following single and repeated nightly administrations of loprazolam, a new benzodiazepine hypnotic. McInnes GT, et al. **Br J Clin Pharmacol** 1985 May;19(5):649-56

Antidepressant properties of the triazolobenzodiazepines alprazolam and adinazolam: studies on the olfactory bulbectomized rat model of depression. O'Connor WT, et al. **Br J Clin Pharmacol** 1985; 19 Suppl 1:49S-56S

Brief review of published alprazolam clinical studies. Straw RN. **Br J Clin Pharmacol** 1985;19 Suppl 1:57S-59S (22 ref.)

Drugs in dentistry. Agents for anxiety disorders. Ciancio SG. **Dent Manage** 1985 Jun;25(6):66, 68, 70

Intramuscular bioavailability of chlorazepate as compared to diazepam. Bertler A, et al. **Eur J Clin Pharmacol** 1985;28(2):229-30

Spontaneous and RO 15-1788-induced reversal of subsensitivity to GABA following chronic benzodiazepines. Gonsalves SF, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):163-70

On the spectrophotometric determination of estazolam using Ru(III) ion. Gallo N, et al. **Farmaco [Prat]** 1985 Mar;40(3):77-80

Behavioral indications for phenothiazine and benzodiazepine tranquilizers in dogs. Hart BL. **J Am Vet Med Assoc** 1985 Jun 1;186(11):1192-4

Alprazolam overdose: clinical findings and serum concentrations in two cases. McCormick SR, et al. **J Clin Psychiatry** 1985 Jun;46(6):247-8

Efficiency and cleanliness of ether extraction for benzodiazepines in blood samples treated with aqueous ammonia compared with other methods for the purpose of HPLC assay. Stevens HM. **J Forensic Sci Soc** 1985 Jan-Feb;25(1):67-79

Triazolam, an anomalous benzodiazepine receptor ligand: in vitro characterization of alprazolam and triazolam binding. Clow A, et al. **J Neurochem** 1985 Aug;45(2):621-5

Comparison of triazolam and pentobarbital: performance impairment, subjective effects and abuse liability. Roache JD, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):120-33

Inhibitory effect on 3H-diazepam binding and potentiating action on GABA of ethyl loflazepate, a new minor tranquilizer. Sakai Y, et al. **Jpn J Pharmacol** 1985 Apr;37(4):373-9

Psychological treatment for benzodiazepine dependence [letter] Tyrer P, et al. **Lancet** 1985 May 4;1(8436):1042-3

Acute pharmacokinetic and pharmacodynamic comparison of two different formulations of temazepam. Mattila MJ, et al. **Med Biol** 1985; 63(1):21-7

Benzodiazepines produce contrasting effects on the active membrane properties of an invertebrate neuron. Tan KS, et al. **Neuropharmacology** 1985 Feb;24(2):91-4

The modulation of cortical acetylcholine release by GABA, GABA-like drugs and benzodiazepines in freely moving guinea-pigs. Tanganelli S, et al. **Neuropharmacology** 1985 Apr;24(4):291-9

Effects of zopiclone and benzodiazepine hypnotics on search in short-term memory. Subhan Z, et al. **Neuropsychobiology** 1984;12(4):244-8

gamma-Aminobutyric acid modulation of benzodiazepine receptor binding in vitro does not predict the pharmacologic activity of all benzodiazepine receptor ligands. Chweh AY, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):173-7

Pharmacology of benzodiazepine antagonists. Haefely W. **Pharmacopsychiatry** 1985 Jan;18(1):163-6

Clinical pharmacology of benzodiazepines. Rickels K. **Pharmacopsychiatry** 1985 Jan;18(1):156-9

1.2-Anellated 1.4-benzodiazepine derivatives--a new class of antipsychotics. Ruhland M, et al. **Pharmacopsychiatry** 1985 Jan; 18(1):174-7

The sedative effects of CL 218,872, like those of chlordiazepoxide, are reversed by benzodiazepine antagonists. File SE, et al. **Psychopharmacology (Berlin)** 1985;85(3):295-300

[Alprazolam (Tafil). A new benzodiazepine-with a new action profile?] Rasmussen SB, et al. **Ugeskr Laeger** 1985 Apr 29;147(18):1495-7 **(Dan)**

[Activity of clobazam on plasma prolactin and gonadotropins after administration of sulpiride in the male rat] Valli M, et al. **Ann Endocrinol (Paris)** 1984;45(6):409-11 (Eng. Abstr.) **(Fre)**

[Characteristics of benzodiazepine consumption in patients hospitalized in an internal medicine department] Le Goc I, et al. **Encephale** 1985 Jan-Feb;11(1):1-6 (Eng. Abstr.) **(Fre)**

[Benzodiazepines: pharmacodynamic aspects] Jacqmin P, et al. **J Pharm Belg** 1985 Jan-Feb;40(1):35-54 (74 ref.) (Eng. Abstr.) **(Fre)**

[Clobazam and N-desmethylclobazam. Assay by HPLC. Application to a pharmacokinetic study] Biehler J, et al. **Therapie** 1985 May-Jun; 40(3):167-71 (Eng. Abstr.) **(Fre)**

[Possible disorders after withdrawal of prolonged treatment with benzodiazepines in man (drug addicts excluded)] Lagier G. **Therapie** 1985 Jan-Feb;40(1):51-7 (Eng. Abstr.) **(Fre)**

[Clinical trial of the action of a benzodiazepine (Lexotan) on the behavior of the anxious patient in dental outpatient care] Debernardi G, et al. **Minerva Stomatol** 1985 Mar-Apr;34(2):323-8 (Eng. Abstr.) **(Ita)**

[Effect of phenazepam on the peripheral catecholaminergic systems in immobilization stress] Malikova LA, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):23-7 (Eng. Abstr.) **(Rus)**

BENZODIAZEPINONES

Effect of H2 receptor- and muscarine receptor antagonists and prostaglandin E1 analog on the gastric mucosal hemodynamics and oxygen sufficiency in rats. Sato N, et al. **Adv Exp Med Biol** 1984; 180:763-71

The effects of a benzodiazepine antagonist Ro 15-1788 in the presence of stable concentrations of midazolam. Lauven PM, et al. **Anesthesiology** 1985 Jul;63(1):61-4

Pharmacokinetics and pharmacodynamics following single and repeated nightly administrations of loprazolam, a new benzodiazepine hypnotic. McInnes GT, et al. **Br J Clin Pharmacol** 1985 May;19(5):649-56

Blockade of the diazepam-induced increase in rat striatal acetylcholine content by the specific benzodiazepine antagonists ethyl-beta-carboline-3-carboxylate and Ro 15-1788. Kolasa K, et al. **Brain Res** 1985 Jun 17;336(2):342-5

Effects of pirenzepine on plasma insulin, glucagon and pancreatic polypeptide levels in normal man. Zaccaria M, et al. **Eur J Clin Pharmacol** 1985;27(6):701-5

The benzodiazepine antagonist Ro 15-1788 reverses the effect of methyl-beta-carboline-3-carboxylate but not of harmaline on cerebellar cGMP and motor performance in mice. Burkard WP, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):241-7

Spontaneous and RO 15-1788-induced reversal of subsensitivity to GABA following chronic benzodiazepines. Gonsalves SF, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):163-70

Kinetics and displacement of [11C]RO 15-1788, a benzodiazepine antagonist, studied in human brain in vivo by positron tomography. Samson Y, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):247-51

Comparative inhibitory effects of pirenzepine and atropine on cholinergic stimulation of exocrine and endocrine rat pancreas. Otsuki M, et al. **Gastroenterology** 1985 Aug;89(2):408-14

Plasma determination of 3-methylclonazepam by capillary gas chromatography. Coassolo P, et al. **J Chromatogr** 1985 Mar 22; 338(2):347-55

1-Azacycloalkyl-1,4-benzodiazepin-2-ones with antianxiety-antidepressant actions. Sugasawa T, et al. **J Med Chem** 1985 Jun;28(6):699-707

'Peripheral-type' binding sites for benzodiazepines in brain: relationship to the convulsant actions of Ro 5-4864. Weissman BA, et al. **J Neurochem** 1985 May;44(5):1494-9

Inhibitory effect on 3H-diazepam binding and potentiating action on GABA of ethyl loflazepate, a new minor tranquilizer. Sakai Y, et al. **Jpn J Pharmacol** 1985 Apr;37(4):373-9

The interaction of McN-A-343 with pirenzepine and other selective muscarine receptor antagonists at a prejunctional muscarine receptor. Choo LK, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb; 328(4):430-8

The effects of benzodiazepines on spinal homosynaptic depression. Davies MF, et al. **Neuropharmacology** 1985 Apr;24(4):301-7

Information processing and benzodiazepines. Kleindienst-Vanderbeke G. **Neuropsychobiology** 1984;12(4):238-43

Clonazepam-induced hyperphagia in nondeprived rats: tests of pharmacological specificity with Ro5-4864, Ro5-3663, Ro15-1788 and CGS 9896. Cooper SJ, et al. **Pharmacol Biochem Behav** 1985 May; 22(5):753-60

NMR analysis of an oligodeoxyribonucleotide-drug adduct: anthramycin-d(ATGCAT). Graves DE, et al. **Prog Clin Biol Res** 1985; 172B:193-205

[Activity of clobazam on plasma prolactin and gonadotropins after administration of sulpiride in the male rat] Valli M, et al. **Ann Endocrinol (Paris)** 1984;45(6):409-11 (Eng. Abstr.) **(Fre)**

[Clobazam and N-desmethylclobazam. Assay by HPLC. Application to a pharmacokinetic study] Biehler J, et al. **Therapie** 1985 May-Jun; 40(3):167-71 (Eng. Abstr.) **(Fre)**

[Effect of phenazepam on the peripheral catecholaminergic systems in immobilization stress] Malikova LA, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):23-7 (Eng. Abstr.) **(Rus)**

BIOGENIC AMINES

Changes in the brain biogenic monoamines of rats, induced by piracetam and aniracetam. Petkov VD, et al. **Acta Physiol Pharmacol Bulg** 1984; 10(4):6-15

Liquid chromatographic determination of free and conjugated 3-methoxy-4-hydroxyphenylethylene glycol with wide-ranging substances related to monoamine metabolism. Ishikawa K, et al. **Anal Biochem** 1985 Jun;147(2):441-50

Role of the spinal monoaminergic systems in suppression of ejaculation by alpha-methyldopa. Kimura Y, et al. **Andrologia** 1985 Mar-Apr; 17(2):166-71

Biogenic amine/metabolite response during in-flight emergencies. Krahenbuhl GS, et al. **Aviat Space Environ Med** 1985 Jun; 56(6):576-80

Monoamine metabolites: their relationship and lack of relationship to monoaminergic neuronal activity. Commissiong JW. **Biochem Pharmacol** 1985 Apr 15;34(8):1127-31

Effects of intraventricular injections of 6-hydroxydopamine on amine metabolites in rat brain and urine. Edwards DJ, et al. **Biochem Pharmacol** 1985 Apr 15;34(8):1255-63

Cerebrospinal fluid (CSF) and brain monoamine metabolites in the developing rat pup. Shaywitz BA, et al. **Brain Res** 1985 Jan; 349(1-2):225-32

Effect of styrene oxide on levels of biogenic amines and activity of monoamine oxidase in different parts of rat brain. Husain R, et al. **Bull Environ Contam Toxicol** 1985 May;34(5):722-9

Pharmacokinetics of oral moclobemide in healthy human subjects and effects on MAO-activity in platelets and excretion of urine monoamine metabolites. Wiesel FA, et al. **Eur J Clin Pharmacol** 1985; 28(1):89-95

Sex differences in long-term gonadectomized rats: monoamine levels and [3H]nitroimipramine binding in brain nuclei. Renner KJ, et al. **Exp Brain Res** 1985;58(1):198-201

Pharmacologic studies of central actions of zopiclone: influence on brain monoamines in rats under stressful condition. Sato K, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Apr;23(4):204-10

New high-performance liquid chromatography system for the separation of biogenic amines as their Dns derivatives. Hayman AR, et al. **J Chromatogr** 1985 Jun 7;325(2):462-6

Modulation by monoamines of somatostatin-sensitive adenylate cyclase on neuronal and glial cells from the mouse brain in primary cultures. Chneiweiss H, et al. **J Neurochem** 1985 Jun;44(6):1825-31

Role of monoamines in experimental spinal cord injury in rats. Relationship between Na+-K+-ATPase and lipid peroxidation. Kurihara M. **J Neurosurg** 1985 May;62(5):743-9

Relationships between drug-induced changes in tetrahydrobiopterin and biogenic amine concentrations in rat brain. Lee EH, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):141-6

Auto-tolerance to the endogenous opioids and sleep. Gillman MA, et al. **Med Hypotheses** 1985 Apr;16(4):393-5

Cardiovascular responses elicited by microinjection of monoamines into mesencephalic nucleus dorsalis raphe in cats. Saxena AK, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):141-5

Mechanisms of the central action of lithium. Sinitskii VN, et al. **Neurosci Behav Physiol** 1985 Jan-Feb;15(1):81-8

Biogenic amine alterations in limbic brain regions of muricidal rats. Broderick PA, et al. **Res Commun Chem Pathol Pharmacol** 1985 Apr; 48(1):3-15

Electrophysiological studies on neuronal transmission in the frog's photosensory pineal organ. The effect of amino acids and biogenic amines. Meissl H, et al. **Vision Res** 1984;24(12):1727-34

[Effect of electroconvulsive shock on brain monoamines] Kuang PG. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1985 Feb; 18(1):41-4 (Eng. Abstr.) **(Chi)**

[A TRH analog (DN-1417). Effects on the levels of monoamines and the metabolites in the various brain regions in rats] Nagai Y, et al. **Nippon Yakurigaku Zasshi** 1985 Apr;85(4):209-20 (Eng. Abstr.) **(Jpn)**

[Changes in the response to the extracellular application of acetylcholine during the intracellular perfusion of isolated neurons with biogenic amines] Turpaev TM, et al. **Dokl Akad Nauk SSSR** 1985; 280(6):1495-8 **(Rus)**

[Biogenic amine content of brain sections, blood and adrenals of rabbits exposed to vibration and noise] Minasian SM, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):439-45 (Eng. Abstr.) **(Rus)**

BIPOLAR DISORDER

Renal function in 153 manic-depressive patients treated with lithium for more than five years. Løkkegaard H, et al. **Acta Psychiatr Scand** 1985 Apr;71(4):347-55

Plasma lithium level and interepisode functioning in bipolar disorder. Goodnick PJ, et al. **Am J Psychiatry** 1985 Jun;142(6):761-2

Manic depression: a multiple hormone disorder? Skutsch GM. **Biol Psychiatry** 1985 Jun;20(6):662-8

Erythrocyte membrane sodium-potassium and magnesium ATPase in primary affective disorder. Thakar JH, et al. **Biol Psychiatry** 1985 Jul; 20(7):734-40

Methylene blue for MDI [letter] Turner WJ. **Biol Psychiatry** 1985 Jul; 20(7):815

Imipramine metabolism in recurrent depressive episodes. Tollefson G, et al. **J Affective Disord** 1985 Mar-Apr;8(2):183-6

Monoamine oxidase inhibitors in the treatment of atypical depression. Zisook S, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):131-7

Lithium therapy for mania and depression. Murray JB. **J Gen Psychol** 1985 Jan;112(1):5-33

Interdependency of lithium ratio, plasma lithium level and clinical state in patients with affective disorders. Elizur A, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(2):167-72

Effects of carbamazepine on cerebrospinal fluid somatostatin. Rubinow DR, et al. **Psychopharmacology (Berlin)** 1985;85(2):210-3

Bipolar disorder and social work practice. Sands RG. **Soc Work Health Care** 1985 Spring;10(3):91-105

[A case of simultaneous treatment of the manic syndrome and granulocytopenia with lithium salts] Greń K, et al. **Psychiatr Pol** 1984 May-Jun;18(3):285-8 **(Pol)**

BLOOD-BRAIN BARRIER

Blood-brain barrier permeability to leucine-enkephalin, D-alanine2-D-leucine5-enkephalin and their N-terminal amino acid (tyrosine). Zlokovic BV, et al. **Brain Res** 1985 Jun 10;336(1):125-32

Role of 5-HT on increased permeability of blood-brain barrier under heat stress. Sharma HS, et al. **Indian J Physiol Pharmacol** 1984 Oct-Dec;

28(4):259-67

[The hemato-encephalic barrier in emotional stress] Belova TI, et al. **Usp Fiziol Nauk** 1985 Apr-Jun;16(2):61-76 (105 ref.) **(Rus)**

BODY IMAGE

Dysmorphophobia [letter] Jenike MA. **Br J Psychiatry** 1985 Mar; 146:326

BRADYKININ

Stimulation of prostacyclin production in isolated rat adipocytes by angiotensin II, vasopressin, and bradykinin: evidence for two separate mechanisms of prostaglandin synthesis. Axelrod L, et al. **Endocrinology** 1985 Jun;116(6):2548-53

BUTYLAMINES

Metabolism of N-nitrodialkylamines. Suzuki E, et al. **IARC Sci Publ** 1984; (57):485-90

BUTYROPHENONE TRANQUILIZERS

Lipids and apolipoproteins in patients treated with major tranquilizers. Sasaki J, et al. **Clin Pharmacol Ther** 1985 Jun;37(6):684-7

[Haloperidol decanoate in replacing combinations of antipsychotic agents in the treatment of chronic schizophrenics] Youssef HA. **Acta Psiquiatr Psicol Am Lat** 1984 Dec;30(4):297-304 **(Spa)**

BUTYROPHENONES

Two 5-HT receptors linked to adenylate cyclase in guinea pig hippocampus are discriminated by 5-carboxamidotryptamine and spiperone. Shenker A, et al. **Eur J Pharmacol** 1985 Mar 12; 109(3):427-9

Pergolide elevation of MHPG sulphate concentration in rat hypothalamus blocked by spiperone and mimicked by other dopamine agonists. Fuller RW, et al. **J Pharm Pharmacol** 1985 Apr;37(4):268-70

A comparison between centrifugation and filtration as a means to separate bound and unbound ligand during 3[H]-spiroperidol binding. Csernansky CA, et al. **J Pharmacol Methods** 1985 Jun;13(3):187-91

Binding of 3H-spiperone to human lymphocytes: a biological marker in schizophrenia? Bondy B, et al. **Psychiatry Res** 1985 May;15(1):41-8

Presynaptic stimulation of dopaminergic CNS structures in sheep as a mechanism of immobilising action of Immobyl (fentanyl + azaperone). Kania BF. **Res Vet Sci** 1985 Mar;38(2):179-83

[Binding of 3H-spiperone in the mouse brain after intraperitoneal injection] Zharkovskiĭ AM, et al. **Biull Eksp Biol Med** 1985 Mar; 99(3):314-5 (Eng. Abstr.) **(Rus)**

CARBAMAZEPINE

Lack of pharmacokinetic interaction of carbamazepine with tranylcypromine [letter] Joffe RT, et al. **Arch Gen Psychiatry** 1985 Jul; 42(7):738

Carbamazepine-induced thrombocytopenia in a young child. Bradley JM, et al. **Clin Pharm** 1985 Mar-Apr;4(2):221-3

The influence of cimetidine on single-dose carbamazepine pharmacokinetics. Dalton MJ, et al. **Epilepsia** 1985 Mar-Apr; 26(2):127-30

A study of some pharmacological actions of carbamazepine and sodium valproate. Mansuri SM, et al. **Indian J Physiol Pharmacol** 1984 Oct-Dec; 28(4):315-8

Bioavailability and central side effects of different carbamazepine tablets. Neuvonen PJ. **Int J Clin Pharmacol Ther Toxicol** 1985 Apr; 23(4):226-32

Differential mediation of the anticonvulsant effects of carbamazepine and diazepam. Weiss SR, et al. **Life Sci** 1985 Jun 24;36(25):2413-9

Effects of carbamazepine on cerebrospinal fluid somatostatin. Rubinow DR, et al. **Psychopharmacology (Berlin)** 1985;85(2):210-3

Erythromycin-carbamazepine interaction [letter] Kessler JM. **S Afr Med J** 1985 Jun 29;67(26):1038

Determination of total and free plasma carbamazepine concentrations by enzyme multiplied immunoassay: interference with the 10,11-epoxide metabolite. Contin M, et al. **Ther Drug Monit** 1985;7(1):46-50

Fallacious results from measuring salivary carbamazepine concentrations. Dickinson RG, et al. **Ther Drug Monit** 1985;7(1):41-5

Simultaneous plasma carbamazepine and carbamazepine-epoxide concentrations in pharmacokinetic and bioavailability studies. Hooper WD, et al. **Ther Drug Monit** 1985;7(1):36-40

[Responsibility of the physician in prescribing Tegretol [letter] Kamp JS. **Ned Tijdschr Geneeskd** 1985 Mar 30;129(13):607-8 **(Dut)**

[Tegretol] Benoit P, et al. **Soins Psychiatr** 1985 Feb;(52):I-II **(Fre)**

[Quantitative determination of carbamazepine in tablets by reverse phase HPLC] Mamolo MG, et al. **Boll Chim Farm** 1984 Dec; 123(12):591-9 (Eng. Abstr.) **(Ita)**

[Interaction of carbamacepine and tuberculostatic agents (letter)] Bastús JB. **Med Clin (Barc)** 1985 Apr 6;84(13):542-3 **(Spa)**

[Clinical pharmacology of carbamazepine--a comparison with phenytoin] Bertilsson L, et al. **Lakartidningen** 1985 Apr 10;82(15):1355-60 **(Swe)**

CARBIDOPA

Carbidopa effect on rat brain monoamine oxidase and pineal melatonin. McIntyre IM, et al. **Biol Psychiatry** 1985 Jul;20(7):809-11

CATATONIA

Severe prolonged catatonia with associated flushing reaction responsive to lithium carbonate. Pheterson AD, et al. **J Am Acad Child Psychiatry** 1985 Mar;24(2):235-7

CATECHOL ESTROGENS

Studies on the effects of catecholestrogens on prolactin secretion by cultured normal rat anterior pituitary cells. Lamberts SW, et al. **Endocrinology** 1985 Jun;116(6):2631-6

Effects of short-term exposure to catecholestrogens on serum concentrations of gonadotrophins and metabolism of catecholestrogens in ovariectomized rats. Ball P, et al. **Horm Metab Res** 1985 Apr; 17(4):184-8

CATECHOLAMINES

Catecholamines and contractility of the human myometrium at term: a possible role for prostaglandins. Wikland M, et al. **Acta Physiol Hung** 1985;65(3):331-4

Determinations of catecholamine half-lives and turnover rates in discrete catecholamine nerve terminal systems of the hypothalamus, the preoptic region and the forebrain by quantitative histofluorimetry. Andersson K, et al. **Acta Physiol Scand** 1985 Apr;123(4):411-26

Sub-aggregatory doses of catecholamines prevent prostacyclin-induced inhibition of platelet aggregation. Buttrick PM, et al. **Am Heart J** 1985 Jun;109(6):1258-63

Methodological considerations in the determination of plasma catecholamines by high-performance liquid chromatography with electrochemical detection. Bouloux P, et al. **Ann Clin Biochem** 1985 Mar;22 (Pt 2):194-203

Computer simulations of the conformations of catecholamine derivatives. Hassan M, et al. **Ann NY Acad Sci** 1985;446:185-98

Plasma norepinephrine, epinephrine, and dopamine levels in end-stage renal disease. Effect of hemodialysis. Elias AN, et al. **Arch Intern Med** 1985 Jun;145(6):1013-5

Brain catecholamines and memory modulation: effects of footshock, amygdala implantation, and stimulation. Welsh KA, et al. **Behav Neural Biol** 1985 Mar;43(2):119-31

Response of hepatic ornithine decarboxylase and polyamine concentration to surgical stress in the rat: evidence for a permissive effect of catecholamines on glucocorticoid action. Corti A, et al. **Biochem Biophys Res Commun** 1985 Jun 28;129(3):885-91

The phorbol ester TPA enhances A23187--but not carbachol- and high K+-induced catecholamine secretion from cultured bovine adrenal chromaffin cells. Morita K, et al. **Biochem Biophys Res Commun** 1985 Jun 14;129(2):511-6

Characterization of protein kinase C and its role in catecholamine secretion from bovine adrenal-medullary cells. Brocklehurst KW, et al. **Biochem J** 1985 May 15;228(1):35-42

Declining catecholamine secretion in adrenal medulla on prolonged stimulation with acetylcholine. Bevington A, et al. **Biochem Pharmacol** 1985 May 1;34(9):1497-500

Interaction of phenothiazine drugs with human ceruloplasmin. Relation between activation of catecholamine neurotransmitter oxidation and electron donating ability of phenothiazine drugs. de Mol NJ. **Biochem Pharmacol** 1985 Aug 1;34(15):2605-9

Affinity-dependent cross-linking to neurotoxin sites of the acetylcholine receptor mediated by catechol oxidation. Nickoloff BJ, et al. **Biochemistry** 1985 Feb 12;24(4):999-1007

Plasma catecholamines and ECT. Khan A, et al. **Biol Psychiatry** 1985 Jul;20(7):799-804

Do catecholamines play a physiologic role in regulating corpus luteum function in the pseudopregnant rabbit? Gadsby JE, et al. **Biol Reprod** 1985 May;32(4):907-15

Hypothalamic epinephrine is released into hypophysial portal blood during stress. Gibbs DM. **Brain Res** 1985 Jun 3;335(2):360-4

Clonidine effects on catecholamine levels and turnover in discrete hypothalamic and extra-hypothalamic areas. Jhanwar-Uniyal M, et al. **Brain Res** 1985 Jun 24;337(1):109-16

Effects of catecholamines on spinal motoneurones and spinal reflex discharges in the isolated spinal cord of the newborn rat. Kitazawa T, et al. **Brain Res** 1985 Mar;351(1):31-6

Place preference conditioning with methylphenidate and nomifensine. Martin-Iverson MT, et al. **Brain Res** 1985 Apr 15;332(1):59-67

Cerebellum plus locus coeruleus in tissue culture: I. Catecholamine histofluorescence and extracellular electrophysiology. Seil FJ, et al. **Brain Res** 1985 Jan;349(1-2):165-70

Intertectal neuronal plasticity in Xenopus laevis: persistence despite catecholamine depletion. Udin SB, et al. **Brain Res** 1985 Mar; 351(1):81–8

Microspectrofluorometric characterization of amine accumulation proximal to lateral hypothalamic lesions. Willis GL, et al. **Brain Res** 1985 May 20;334(2):344–7

Amine accumulation in behavioural pathology. Willis GL, et al. **Brain Res** 1985 Jun;356(2):109–32 (302 ref.)

Ultrastructural evidence of direct synaptic contact of catecholamine terminals with oxytocin–containing neurons in the parvocellular portion of the rat hypothalamic paraventricular nucleus. Yamano M, et al. **Brain Res** 1985 Jun 10;336(1):176–9

Catecholamine innervation of cervical dendrite bundles: possible phrenic nucleus innervation. Bellinger DL, et al. **Brain Res Bull** 1984 Dec; 13(6):701–7

MPTP alters central catecholamine neurons in addition to the nigrostriatal system. Gupta M, et al. **Brain Res Bull** 1984 Dec;13(6):737–42

Effect of delta 9–THC on brain and plasma catecholamine levels as measured by HPLC. Patel V, et al. **Brain Res Bull** 1985 Jan; 14(1):85–90

Plasticity of catecholaminergic neurons in aged rat brain: reinnervation and functional recovery after axotomy. Phelps CJ, et al. **Brain Res Bull** 1984 Dec;13(6):727–36

Early appearance of catecholaminergic neurons in the central nervous system of precocial and altricial avian species. A fluorescence–histochemical study. Guglielmone R, et al. **Cell Tissue Res** 1985;240(2):381–4

Cortisol and catecholamines response to venisection by humans with different blood groups. Locong AH, et al. **Clin Biochem** 1985 Feb; 18(1):67–9

Acetaminophen administration interferes with urinary metanephrine (and catecholamine) determinations [letter] Wilson SP, et al. **Clin Chem** 1985 Jun;31(6):1093–4

Receptor mechanisms in fish chromatophores—VIII. Mediated by beta adrenoceptors, catecholamines always act to disperse pigment in siluroid melanophores. Fujii R, et al. **Comp Biochem Physiol** [C] 1985; 81(1):1–6

Catecholamine hormones and the control of avian salt glands. Wilson JX, et al. **Comp Biochem Physiol** [C] 1985;81(1):77–9

Cardiovascular and catecholamine responses to hypoxemia in chemically sympathectomized fetal lambs. Lewis AB, et al. **Dev Pharmacol Ther** 1985;8(2):129–40

Effect of intravenous ketanserin on plasma catecholamines and renin activity in normal volunteers. Reimann IW, et al. **Eur J Clin Pharmacol** 1985;28(3):273–7

Pharmacological interference with the neurotoxic action of 1–methyl–4–phenyl–1,2,3,6–tetrahydropyridine (MPTP) on central catecholamine neurons in the mouse. Sundström E, et al. **Eur J Pharmacol** 1985 Apr 16;110(3):293–9

Effects of intracerebroventricular 6–hydroxydopamine on catecholaminergic fibers in the rat hypothalamus. Hwang BH, et al. **Exp Neurol** 1985 May;88(2):336–48

Changes in the size of isolated chromaffin granules in ATP–evoked catecholamine release. Warashina A. **FEBS Lett** 1985 May 6; 184(1):87–9

Hormonal influence on the response of the uterus of the Brazilian marsupial Didelphis albiventris to adrenergic drugs. Rocha LR, et al. **Gen Comp Endocrinol** 1985 May;58(2):179–85

Immunohistochemical demonstration of catecholaminergic cell bodies in the spinal cord of the rat. Preliminary note. Dietl M, et al. **Histochemistry** 1985;82(4):385–9

Effect of phosphodiesterase regulators and catecholamines on motility of isolated pregnant rat uterus. Singh M, et al. **Indian J Exp Biol** 1984 Dec;22(12):645–8

Pharmacologic studies of the central action of zopiclone: effects on locomotor activity and brain monoamines in rats. Liu HJ, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Mar;23(3):121–8

Brain catecholamines and the central control of food intake. Stricker EM, et al. **Int J Obes** 1984;8 Suppl 1:39–50 (64 ref.)

Sympathetic activity, plasma renin activity (PRA) and kininogen levels in patients haemodialysed with acetate and bicarbonate. Ksiażek A, et al. **Int Urol Nephrol** 1984;16(4):337–44

Exercise, dobutamine, and combined atropine, norepinephrine, and epinephrine compared. Haidet GC, et al. **J Appl Physiol** 1985 Jun; 58(6):2047–53

The effects of hypoxia on catecholamine dynamics in the rat carotid body. Brokaw JJ, et al. **J Auton Nerv Syst** 1985 May;13(1):35–47

Vasoactive amines modulate actin cables (stress fibers) and surface area in cultured bovine endothelium. Welles SL, et al. **J Cell Physiol** 1985 Jun;123(3):337–42

Simultaneous assay of 3,4–dihydroxyphenylalanine, catecholamines and O–methylated metabolites in human plasma using high–performance liquid chromatography. Ishimitsu T, et al. **J Chromatogr** 1985 Feb 8; 337(2):239–48

Catecholamine secretion as a function of perceived coping self–efficacy. Bandura A, et al. **J Consult Clin Psychol** 1985 Jun;53(3):406–14

Radioreceptor assay for beta–adrenergic receptor–reactive catecholamines in serum samples. Iwo K, et al. **J Lab Clin Med** 1985 Jun; 105(6):711–7

The effect of acute lithium administration on brain monoamine synthesis and the precursor amino acids tyrosine and tryptophan in brain and plasma in rats. Berggren U. **J Neural Transm** 1985;61(3–4):175–81

Direct fluorometric assay of catecholamine secretion from isolated bovine adrenal chromaffin cells. Lelkes PI, et al. **J Neurosci Methods** 1985 May;13(3–4):249–55

An improved technique for extracting catecholamines from body fluids. Macdonald IA, et al. **J Neurosci Methods** 1985 May;13(3–4):239–48

Photoaffinity labelling of MSH receptors on Anolis melanophores: effects of catecholamines, calcium and forskolin. Eberle AN, et al. **J Recept Res** 1985;5(1):59–81

Regional changes in catecholamine content of the pregnant uterus. Arkinstall SJ, et al. **J Reprod Fertil** 1985 Mar;73(2):547–57

Changes in dopamine–beta–hydroxylase, and copper, and catecholamine concentrations in human plasma with physical exercise. Ohno H, et al. **J Sports Med Phys Fitness** 1984 Dec;24(4):315–20

Glucose and insulin infusion directly after cardiac surgery: effects on systemic glucose uptake, catecholamine excretion, O2 consumption, and CO2 production. Nilsson F, et al. **JPEN** 1985 Mar–Apr;9(2):159–64

Effect of 2,4,6–trinitrophenol on catecholamine secretion from perfused bovine adrenal glands. Yamanaka K, et al. **Jpn J Pharmacol** 1985 Jan; 37(1):120–3

Hormonal control of renal potassium excretion. Field MJ, et al. **Kidney Int** 1985 Feb;27(2):379–87 (86 ref.)

The effects of a single acute dose of dexamethasone on monoamine and metabolite levels in rat brain. Rothschild AJ, et al. **Life Sci** 1985 Jul 1;36(26):2491–501

The effects of acute and chronic treatment with triiodothyronine and thyroxine on the hypothalamic and telencephalic catecholamine nerve terminal systems of the hypophysectomized male rat. Chronic treatment modulates catecholamine utilization in discrete catecholamine nerve terminal systems. Andersson K, et al. **Neuroendocrinology** 1985 May; 40(5):398–408

Influences of catecholamines on growth hormone release in female goldfish, Carassius auratus. Chang JP, et al. **Neuroendocrinology** 1985 Jun;40(6):463–70

A combined autoradiographic and immunocytochemical study of 3H–corticosterone target neurons and catecholamine neurons in rat and mouse lower brain stem. Duncan GE, et al. **Neuroendocrinology** 1985 Mar;40(3):262–71

Central and peripheral catecholamine innervation of the rat intermediate and posterior pituitary lobes. Saavedra JM. **Neuroendocrinology** 1985 Apr;40(4):281–4

Comparison of the changes in central catecholamine systems following short– and long–term lithium treatment and the consequences of lithium withdrawal. Ahluwalia P, et al. **Neuropsychobiology** 1984; 12(4):217–23

State of adrenergic and cholinergic systems in schizophrenia patients during psychopharmacotherapy. Krupenina LB, et al. **Neurosci Behav Physiol** 1985 Jan–Feb;15(1):1–8

Morphological evidence that serotonin–immunoreactive neurons in the nucleus dorsomedialis hypothalami could be under catecholaminergic influence. Arezki F, et al. **Neurosci Lett** 1985 May 14;56(2):161–6

Reflex changes in sympatho–adrenal medullary functions in response to various thermal cutaneous stimulations in anesthetized rats. Kurosawa M, et al. **Neurosci Lett** 1985 May 14;56(2):149–54

Effects of gonadal steroids on catecholamine levels in the brain of the oyster toadfish. Pennypacker KR, et al. **Neurosci Lett** 1985 Apr 9; 55(2):203–6

Effects of intravenously administered 6–hydroxydopamine on the content of monoamines in the median eminence and neurointermediate lobe of the rat. Sheward WJ, et al. **Neurosci Lett** 1985 Apr 9;55(2):141–4

Chlordecone interaction with catecholamine binding and uptake in rat brain synaptosomes. Desaiah D. **Neurotoxicology (Little Rock Ar)** 1985 Spring;6(1):159–65

Effect of dialysate sodium on the dopamine, adrenaline and noradrenaline concentration in haemodialysis patients. Ksiażek A, et al. **Proc Eur Dial Transplant Assoc Eur Ren Assoc** 1985;21:225–9

Prostaglandins, catecholamines, and differentiation of the secondary palate. Greene RM, et al. **Prog Clin Biol Res** 1985;163C:277–81

Effects of ketamine on the catecholamine containing cells of the adrenal gland of the lizard Podarcis s. sicula Raf. Varano L, et al. **Res Commun Chem Pathol Pharmacol** 1985 Apr;48(1):145–8

Effects of nicotinic an muscarinic stimulation on calcium flux and catecholamine secretion in primary cultures of adrenal medullary cells. Watanabe J. **Tokushima J Exp Med** 1984 Dec;31(3–4):79–84

[Central neurotransmitters and cardiovascular activity] Xia Y. **Sheng Li Ko Hsueh Chin Chan** 1985 Jan;16(1):27–31 (50 ref.) (Ch

[Expression of the adrenergic phenotype by dorsal root ganglion cells of the quail in culture in vitro] Xue ZG, et al. **C R Acad Sci [III]** 1985;300(13):483–8 (Eng. Abstr.) (Fre)

[Concentrations of catecholamines in CSF and plasma, and cardiovascular effects following epidural administration of 2 mg epinephrine] Nakajima

J. **Masui** 1985 Feb;34(2):144-51 (Eng. Abstr.) **(Jpn)**

[Neuro-intestinal peptides and peptide-producing cells--immunohistocytochemistry of catecholamines and opioid peptides in the hamster adrenal medulla] Kobayashi S, et al. **Nippon Heikatsukin Gakkai Zasshi** 1984 Oct;20(5):393-9 **(Jpn)**

[Catecholamine content in the human adrenal gland] Nakada T, et al. **Nippon Hinyokika Gakkai Zasshi** 1985 Feb;76(2):239-43 (Eng. Abstr.) **(Jpn)**

[Spatial reorganization of the organelles of catecholamine-synthesizing group A1 neurons during emotional stress] Zhigadlo BA, et al. **Arkh Anat Gistol Embriol** 1985 Feb;88(2):11-6 (Eng. Abstr.) **(Rus)**

[Catecholamine levels in pancreatic tissue after intraperitoneal administration of acetylcholine] Gal'kiv MA, et al. **Fiziol Zh** 1985 Mar-Apr;31(2):230-4 **(Rus)**

[Cardiomyocytes in monolayer culture and the effect on them of catecholamines and hypoxia] Gurevich MI, et al. **Fiziol Zh** 1985 May-Jun;31(3):267-72 (Eng. Abstr.) **(Rus)**

[Biogenic amine content of various parts of the brain under the stimulation of interoceptors of the gastrointestinal tract] Kravets SV, et al. **Fiziol Zh** 1985 Mar-Apr;31(2):216-9 **(Rus)**

[Changes in blood monoamine and 11-hydroxycorticosteroid levels in rats under the action of stress] Ugarova OP. **Fiziol Zh** 1985 Mar-Apr; 31(2):224-7 **(Rus)**

[Effect of gamma-aminobutyric acid, taurine and catecholamines on the synaptic processes in Lorenzini's ampules in Black Sea skates] Akoev GN, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):466-71 (Eng. Abstr.) **(Rus)**

[Cytophotometric study of catecholamines and acetylcholinesterase in neurons of the intramural plexus of the urinary bladder of the cat in controls and animals exposed to experimental conditions] Lapsha VI, et al. **Neirofiziologiia** 1985;17(2):263-70 (Eng. Abstr.) **(Rus)**

CENTRAL NERVOUS SYSTEM AGENTS

Characteristics of the cortical and hippocampal EEG power spectra of rabbits during normal behavioral states and after administration of CNS acting drugs. Yamamoto J. **Jpn J Pharmacol** 1985 Mar;37(3):227-34

Drugs and chemicals that act on the central nervous system: interpretation of experimental evidence. Kellogg CK. **Prog Clin Biol Res** 1985; 163C:147-53 (27 ref.)

CHILD BEHAVIOR DISORDERS

Treatment of an aggressive, compulsive adolescent with sultopride [letter] Bucci L. **Am J Psychiatry** 1985 Jul;142(7):882-3

CHILD DEVELOPMENT DISORDERS

Understanding and treatment of childhood depression. Aylward GP. **J Pediatr** 1985 Jul;107(1):1-9

CHLORAMINES

A possible origin of chemiluminescence in phagocytosing neutrophils. Reaction between chloramines and H2O2. Zgliczyński JM, et al. **Int J Biochem** 1985;17(4):515-9

Generation of free radical intermediates from foreign compounds by neutrophil-derived oxidants. Kalyanaraman B, et al. **J Clin Invest** 1985 May;75(5):1618-22

[In vitro antibacterial activity of chloramide] Farina C, et al. **G Ital Chemioter** 1984 Sep-Dec;31(3):215-8 (Eng. Abstr.) **(Ita)**

CHLORDIAZEPOXIDE

Chlordiazepoxide toxicity in Limbitrol overdose [letter] Goethe JW, et al. **Am J Psychiatry** 1985 Jun;142(6):774

Comparison of limbitrol (chlordiazepoxide/amitriptyline) and amitriptyline alone as a single night-time dose for the treatment of depression with anxiety. James RT, et al. **J Int Med Res** 1985; 13(2):84-7

Brain amines and effects of chlordiazepoxide on motor activity in response to stress. Freeman GB, et al. **Pharmacol Biochem Behav** 1985 May; 22(5):665-70

The effects of d-amphetamine, chlordiazepoxide and alpha-flupenthixol on food-reinforced tracking of a visual stimulus by rats. Evenden JL, et al. **Psychopharmacology (Berlin)** 1985;85(3):361-6

The sedative effects of CL 218,872, like those of chlordiazepoxide, are reversed by benzodiazepine antagonists. File SE, et al. **Psychopharmacology (Berlin)** 1985;85(3):295-300

A comparison between chlordiazepoxide and CL 218,872--a synthetic nonbenzodiazepine ligand for benzodiazepine receptors on spontaneous locomotor activity in rats. McElroy JF, et al. **Psychopharmacology (Berlin)** 1985;85(2):224-6

[Effect of stable strontium on spontaneous and drug-induced motor activity in the rat] Escanero JF, et al. **Arch Farmacol Toxicol** 1985 Apr; 11(1):33-9 (Eng. Abstr.) **(Spa)**

P-CHLOROPHENYLALANINE

Decreased serotonin content of embryonic raphe neurons following maternal administration of p-chlorophenylalanine: a quantitative immunocytochemical study. Lauder JM, et al. **Brain Res** 1985 May; 352(1):107-14

CHLORPROMAZINE

Chlorpromazine-associated haemolysis in anorexia nervosa. Van der Weyden MB, et al. **Acta Haematol (Basel)** 1985;73(2):111-3

Comparison of inhibitory actions of chlorpromazine or its 7,8-dihydroxy and 7,8-dioxo-didesmethyl analogs on DA-sensitive adenylate cyclase and calmodulin activation of phosphodiesterase in rat striatum. Palmer GC, et al. **Arch Int Pharmacodyn Ther** 1985 Feb;273(2):202-11

Effects of chlorpromazine and its dihydroxy metabolite on calcium movement and electrical activity in superior cervical ganglia. Guzman-Harty M, et al. **Arch Toxicol** 1985 Feb;56(4):272-8

Inhibitory effect of chlorpromazine on bone formation in vivo and in vitro. Komoda T, et al. **Biochem Pharmacol** 1985 Jul 1; 34(13):2389-91

Drug-protein interactions: binding of chlorpromazine to calmodulin, calmodulin fragments, and related calcium binding proteins. Marshak DR, et al. **Biochemistry** 1985 Jan 1;24(1):144-50

Chlorpromazine inhibition of electron transport in Azotobacter vinelandii membranes. Wong TY, et al. **Biochim Biophys Acta** 1985 May 31; 807(3):320-3

The mechanism of intestinal transport of sulfamethoxazole and the effect of chlorpromazine in rat everted intestine. Chung YH, et al. **J Pharmacobiodyn** 1985 Feb;8(2):142-9

Comparison of chlorpromazine, haloperidol and pimozide in the treatment of phencyclidine psychosis: DA-2 receptor specificity. Giannini AJ, et al. **J Toxicol Clin Toxicol** 1984-85;22(6):573-9

Effect of chlorpromazine on peritoneal clearances. Indraprasit S, et al. **Nephron** 1985;40(3):341-3

Effect of centrally acting drugs on ethanol detoxification enzymes in distinct rat brain regions. Messiha FS. **Neurobehav Toxicol Teratol** 1985 Mar-Apr;7(2):181-4

Drug interactions and vasoconstrictors used in local anesthetic solutions. Yagiela JA, et al. **Oral Surg Oral Med Oral Pathol** 1985 Jun; 59(6):565-71

Temperature dependent modification of radiosensitivity following hypoxic cytocidal action of chlorpromazine. Shenoy MA, et al. **Radiat Environ Biophys** 1985;24(2):113-7

Thorazine injected; pt. dies: criminal charges. Case in point: people v. Nygren (696 P. 2d 270--CO). Tammelleo AD. **Regan Rep Nurs Law** 1985 May;25(12):2

[Effects of haloperidol, chlorpromazine, metoclopramide and ascorbic acid on adrenergic salivation and lacrimation in mice at an ambient temperature of 30 degrees C] Li BH, et al. **Chung Kuo Yao Li Hsueh Pao** 1985 Mar;6(1):24-6 (Eng. Abstr.) **(Chi)**

[A simple phosphorimetric method for the determination of chlorpromazine] Huang RH, et al. **Yao Hsueh Hsueh Pao** 1984 Aug; 19(8):606-10 (Eng. Abstr.) **(Chi)**

[Biotransformation of Chlorphenethazin (Elroquil, Marophen)] Pfeifer S, et al. **Pharmazie** 1985 Jan;40(1):37-9 (Eng. Abstr.) **(Ger)**

CHLORPROTHIXENE

Determination of chlorprothixene and its sulfoxide metabolite in plasma by high-performance liquid chromatography with ultraviolet and amperometric detection. Brooks MA, et al. **J Chromatogr** 1985 Feb 8;337(2):351-62

Tetracyclic pyridazines as potential psychopharmacological agents. Ross BS, et al. **J Med Chem** 1985 Jul;28(7):870-5

CHOICE BEHAVIOR

The effects of delaying reward on choice preference in rats with hippocampal or selective septal lesions. Rawlins JN, et al. **Behav Brain Res** 1985 May;15(3):191-203

Differential effects of pimozide on response-rate and choice accuracy in a self-stimulation paradigm in mice. Bowers W, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):521-6

CLOMIPRAMINE

Chlorimipramine, electroconvulsive shock and combination thereof: differential effects of chronic treatment on apomorphine-induced behaviours and on striatal and mesocortical dopamine turnover. Spyraki C, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):128-34

Role of the serotonin uptake carrier in the neurochemical response to methamphetamine: effects of citalopram and chlorimipramine. Schmidt CJ, et al. **Neurochem Res** 1985 May;10(5):637-48

Clomipramine and imipramine in obsessive-compulsive disorder. Volavka J, et al. **Psychiatry Res** 1985 Jan;14(1):85-93

[Treatment of obsessive compulsive neurosis] Greenberg D, et al. **Harefuah** 1985 Mar 1;108(5):231-5 (Eng. Abstr.) **(Heb)**

COCAINE

Atomizer modification for nasal administration of cocaine and other drugs. Rector FT, et al. **Anesth Analg** 1985 Jul;64(7):739-41

Carl Koller: the man and the drug. McAuley JE. **Br Dent J** 1985 May 11;158(9):339-42

Frequency-related, bidirectional limbic responses to cocaine: comparisons with amphetamine and lidocaine. Lesse H, et al. **Brain Res** 1985 May 27;335(1):21-31

Cocaine increases EEG beta: a replication and extension of Hans Berger's historic experiments. Herning RI, et al. **Electroencephalogr Clin Neurophysiol** 1985 Jun;60(6):470-7

Platelet responsiveness and biosynthesis of thromboxane and prostacyclin in response to in vitro cocaine treatment. Togna G, et al. **Haemostasis** 1985;15(2):100-7

An epidemic of cocaine associated deaths in Utah. Sander R, et al. **J Forensic Sci** 1985 Apr;30(2):478-84

The danger of cocaine [editorial] Pollin W. **JAMA** 1985 Jul 5; 254(1):98

Bromocriptine as treatment of cocaine abuse [letter] Dackis CA, et al. **Lancet** 1985 May 18;1(8438):1151-2

Catecholamine-independent behavioral and neurochemical effects of cocaine in rats. Gale K. **Natl Inst Drug Abuse Res Monogr Ser** 1984; 54:323-32

Sensitization of rotational behavior produced by a single exposure to cocaine. Guan LC, et al. **Pharmacol Biochem Behav** 1985 May; 22(5):901-3

[A brief review on cocaine] Renggli R. **Schweiz Med Wochenschr** 1985 Mar 30;115(13):426-30 (15 ref.) (Eng. Abstr.) (Ger)

[Fatal cocaine poisoning] Kisser W. **Z Rechtsmed** 1985;94(2):155-8 (Eng. Abstr.) (Ger)

COGNITION

Comparison of triazolam and pentobarbital: performance impairment, subjective effects and abuse liability. Roache JD, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):120-33

Information processing and benzodiazepines. Kleindienst-Vanderbeke G. **Neuropsychobiology** 1984;12(4):238-43

COMPULSIVE BEHAVIOR

Treatment of an aggressive, compulsive adolescent with sultopride [letter] Bucci L. **Am J Psychiatry** 1985 Jul;142(7):882-3

CONDITIONING (PSYCHOLOGY)

Associative conditioning analog selectively increases cAMP levels of tail sensory neurons in Aplysia. Ocorr KA, et al. **Proc Natl Acad Sci USA** 1985 Apr;82(8):2548-52

Anxiolytic drugs and the acquisition of conditioned fear in mice. Sanger DJ, et al. **Psychopharmacology (Berlin)** 1985;85(3):284-8

CONDITIONING, CLASSICAL

Direct and indirect behavioral pathways to the social transmission of food avoidance. Galef BG Jr. **Ann NY Acad Sci** 1985;443:203-15

Introduction: physiological mechanisms in conditioned taste aversions. Grill HJ. **Ann NY Acad Sci** 1985;443:67-88

GABA effect on conditioned reflex responses in teleost. Ivanuš J, et al. **Ann NY Acad Sci** 1985;444:543-6

Conditioned food aversions and satiety signals. Kulkosky PJ. **Ann NY Acad Sci** 1985;443:330-47

Conditioned taste aversions: a behavioral index of toxicity. Riley AL, et al. **Ann NY Acad Sci** 1985;443:272-92

Glucocorticoid and other hormonal substrates of conditioned taste aversion. Smotherman WP. **Ann NY Acad Sci** 1985;443:126-44

Interfering with taste aversion learning in rats: the role of associative interference. Cannon DS, et al. **Appetite** 1985 Mar;6(1):1-19

Potentiation and overshadowing in preweanling and adult rats. Kucharski D, et al. **J Exp Psychol [Anim Behav]** 1985 Jan;11(1):15-34

Conditioned taste aversion suppresses induction of delayed-type hypersensitivity immune reactions. Kelley KW, et al. **Physiol Behav** 1985 Feb;34(2):189-93

CONDITIONING, OPERANT

Arginine vasopressin inoculates against age-related changes in temporal memory. Meck WH, et al. **Ann NY Acad Sci** 1985;444:453-6

Physostigmine reverses memory deficits produced by pretraining electrical stimulation of the dorsal hippocampus in mice. Micheau J, et al. **Behav Brain Res** 1985 Apr;15(2):75-81

Effects of acute oral administration of lithium compounds on multiple schedule performance in rats. Chrislip DW, et al. **Neurobehav Toxicol Teratol** 1985 Jan-Feb;7(1):39-42

Differential effects of pimozide on response-rate and choice accuracy in a self-stimulation paradigm in mice. Bowers W, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):521-6

Neuroleptic-induced deficits in operant responding for temperature reinforcement. Ettenberg A, et al. **Pharmacol Biochem Behav** 1985 May; 22(5):761-7

Effects of neuroleptics on rate and duration of operant versus reflexive licking in rats. Gramling SE, et al. **Pharmacol Biochem Behav** 1985 Apr; 22(4):541-5

Effects of phenytoin, phenobarbital, and valproic acid, alone and in selected combinations, on schedule-controlled behavior of rats. Picker M, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):389-93

Haloperidol and nonreinforcement produce different patterns of response slowing in a food reinforced runway task. Wirtshafter D, et al. **Pharmacol Biochem Behav** 1985 May;22(5):661-3

The effects of d-amphetamine, chlordiazepoxide and alpha-flupenthixol on food-reinforced tracking of a visual stimulus by rats. Evenden JL, et al. **Psychopharmacology (Berlin)** 1985;85(3):361-6

Methylphenidate: rate-dependent drug effects in hyperactive boys. Weber K. **Psychopharmacology (Berlin)** 1985;85(2):231-5

CONFLICT (PSYCHOLOGY)

Prenatal stress impairs maternal behavior in a conflict situation and reduces hippocampal benzodiazepine receptors. Fride E, et al. **Life Sci** 1985 Jun 3;36(22):2103-9

CORTICOSTERONE

Pharmacology of the steroid regulation of transmitter choice in cultured rat sympathetic ganglia. McLennan IS, et al. **Aust J Exp Biol Med Sci** 1984 Oct;62 (Pt 5):627-39

Phospholipids, sterol carrier protein2 and adrenal steroidogenesis. Vahouny GV, et al. **Biochim Biophys Acta** 1985 May 17; 834(3):324-30

Effect of fetal decapitation on unbound rat plasma corticosterone concentration at the end of pregnancy. Cohen A, et al. **Biol Neonate** 1985;47(3):163-9

Corticosterone modulation of neurotransmitter receptors in rat hippocampus: a quantitative autoradiographic study. Biegon A, et al. **Brain Res** 1985 Apr 22;332(2):309-14

The development of the glucocorticoid receptor system in the rat limbic brain. I. Ontogeny and autoregulation. Meaney MJ, et al. **Brain Res** 1985 Feb;350(1-2):159-64

The development of the glucocorticoid receptor system in the rat limbic brain. III. Negative-feedback regulation. Sapolsky RM, et al. **Brain Res** 1985 Feb;350(1-2):169-73

Effects of steroid hormones on the neuropil of the hypothalamic paraventricular nucleus of male chickens. Panzica GC, et al. **Cell Tissue Res** 1985;240(1):169-74

Effects of corticotropin-releasing factor (CRF) on aldosterone and 18-hydroxycorticosterone secretion. Maser-Gluth C, et al. **Clin Exp Hypertens [A]** 1984;6(10-11):2097-100

Cytochemical and cytophysiological studies of gonadotropin-releasing hormone (GnRH) target cells in the male rat pituitary: differential effects of androgens and corticosterone on GnRH binding and gonadotropin release. Tibolt RE, et al. **Endocrinology** 1985 Jul;117(1):396-404

Androstenedione or corticosterone treatment during pregnancy alters estrous cycle of adult female offspring in mice. Harvey PW, et al. **Experientia** 1985 Apr 15;41(4):492-4

Effects of chronic changes in dietary electrolytes and acute stress on plasma levels of corticosterone and aldosterone in the duck (Anas platyrhynchos). Klingbeil CK. **Gen Comp Endocrinol** 1985 Apr; 58(1):10-9

Changes in hormone levels in relation to breeding behavior in male bullfrogs (Rana catesbeiana) at the individual and population levels. Mendonça MT, et al. **Gen Comp Endocrinol** 1985 May;58(2):270-9

Inhibition of the ACTH adrenal response to stress by treatment with hydrocortisone, prednisolone and dexamethasone in the rat. Baumann JB, et al. **Horm Res** 1985;21(4):254-60

Alterations in the activities of subcellular fractions marker enzymes in rat liver and brain by hydrocortisone and corticosterone treatment. Garcia MV, et al. **Int J Biochem** 1985;17(2):203-8

The stimulation of lipogenesis in white adipose tissue from fed rats by corticosterone. Minshull M, et al. **Int J Biochem** 1985;17(4):529-32

In vitro metabolism of [3H] corticosterone by mammary glands from lactating rats. Isolation and identification of 21-acyl[3H]corticosterone. Pearlman WH, et al. **J Biol Chem** 1985 May 10;260(9):5296-301

Thymosin fraction 5 causes increased serum corticosterone in rodents in vivo. McGillis JP, et al. **J Immunol** 1985 Jun;134(6):3952-5

Muscarinic receptor subclasses in the chick embryo retina: influence of corticosterone treatment. Gremo F, et al. **J Neurochem** 1985 Aug; 45(2):345-51

Eighteen-deoxyaldosterone and other less polar forms of 18-hydroxycorticosterone as aldosterone precursors in rat adrenals

Cozza EN, et al. **J Steroid Biochem** 1985 May;22(5):665-72

Comparison of the distribution kinetics and metabolism to acid end-products of corticosterone and 11-deoxycorticosterone in BALB/c mice. Marandici A, et al. **J Steroid Biochem** 1985 Apr;22(4):539-45

Dissociation between adrenocorticotropin and corticosterone responses to restraint after previous chronic exposure to stress. Armario A, et al. **Life Sci** 1985 Jun 3;36(22):2085-92

A combined autoradiographic and immunocytochemical study of 3H-corticosterone target neurons and catecholamine neurons in rat and mouse lower brain stem. Duncan GE, et al. **Neuroendocrinology** 1985 Mar;40(3):262-71

ACTH and corticosterone secretion in rats following removal of the neurointermediate lobe of the pituitary gland. Fagin KD, et al. **Neuroendocrinology** 1985 Apr;40(4):352-62

Involvement of the sensory cortex in adrenocortical responses following photic and acoustic stimulation in the rat. Feldman S, et al. **Neurosci Lett** 1985 Apr 9;55(2):249-53

The effect of adrenalectomy and corticosterone on homotypic collateral sprouting of serotonergic fibers in hippocampus. Zhou FC, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):111-6

Effects of emotional stress on the immune system. Miller NE. **Pavlov J Biol Sci** 1985 Apr-Jun;20(2):47-52

Comparative biochemical responses of rats to different stressful stimuli. Odio MR, et al. **Physiol Behav** 1985 Apr;34(4):595-9

Maturation of the diurnal rhythm of corticosterone in female domestic fowl. Webb ML, et al. **Poult Sci** 1985 Apr;64(4):744-50

Increase in plasma ACTH after dopaminergic stimulation in rats. Ježová D, et al. **Psychopharmacology (Berlin)** 1985;85(2):201-3

In vivo effects of glucocorticoids on serum corticosterone levels in rats. Yamada K, et al. **Res Commun Chem Pathol Pharmacol** 1985 Mar; 47(3):441-4

[Appraisal of ultradian components in the ethosecretogram of rat] Shiraishi I. **Hokkaido Igaku Zasshi** 1985 Jan;60(1):66-81 (Eng. Abstr.) **(Jpn)**

[Development of a photoperiod-controllable clean rack for rats: circadian rhythms of water intake and blood corticosterone levels] Torii R, et al. **Jikken Dobutsu** 1985 Jan;34(1):57-62 (Eng. Abstr.) **(Jpn)**

CORTICOTROPIN

The effect of nifedipine on CRF-41 and AVP-induced ACTH release in vitro. Murakami K, et al. **Acta Endocrinol (Copenh)** 1985 May; 109(1):32-6

Opiomelanocorticotropic-like hormones in Vipera aspis pituitary. Uva B, et al. **Acta Histochem (Jena)** 1985;76(1):81-7

Somatostatin inhibition of cyclic AMP accumulation and adrenocorticotropin release from mouse anterior pituitary tumor cells: mode of action and self-regulation. Reisine TD. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:169-77

Distribution of the pro-opiomelanocortin derived peptides, adrenocorticotrope hormone, alpha-melanocyte-stimulating hormone and beta-endorphin (ACTH, alpha-MSH, beta-END) in the rat hypothalamus. Mezey E, et al. **Brain Res** 1985 Mar 4;328(2):341-7

Blood pressure responses to ACTH and adrenaline infusions in dogs. Anderson WP, et al. **Clin Exp Hypertens [A]** 1985;7(4):525-37

Acute and chronic effects of ACTH on thermogenesis and brown adipose tissue in the rat. Rothwell NJ, et al. **Comp Biochem Physiol [A]** 1985; 81(1):99-102

Re-evaluation of 'frontal deafferentation' studies on the regulation of ACTH secretion in the light of CRF immunohistology. Lengvári I, et al. **Endocrinol Exp (Bratisl)** 1985 Mar;19(1):3-9

Changes induced in rabbit plasma and aqueous humour by ACTH4-10 and ACTH1-24. Stárka L, et al. **Endocrinol Exp (Bratisl)** 1985 Mar; 19(1):25-8

Corticotropin-releasing factor stimulation of adrenocorticotropin and beta-endorphin release: effects of acute and chronic stress. Young EA, et al. **Endocrinology** 1985 Jul;117(1):23-30

Inhibition of the ACTH adrenal response to stress by treatment with hydrocortisone, prednisolone and dexamethasone in the rat. Baumann JB, et al. **Horm Res** 1985;21(4):254-60

Bacterial lipopolysaccharide induction of leukocyte-derived corticotropin and endorphins. Harbour-McMenamin D, et al. **Infect Immun** 1985 Jun; 48(3):813-7

Lack of renal effects of DOCA, ACTH, spironolactone, and angiotensin II in Squalus acanthias. Churchill PC, et al. **J Exp Zool** 1985 Apr; 234(1):17-22

Dissociation between adrenocorticotropin and corticosterone responses to restraint after previous chronic exposure to stress. Armario A, et al. **Life Sci** 1985 Jun 3;36(22):2085-92

ACTH and corticosterone secretion in rats following removal of the neurointermediate lobe of the pituitary gland. Fagin KD, et al. **Neuroendocrinology** 1985 Apr;40(4):352-62

Development of hypothalamic opioid neurons: a combined immunocytochemical and [3H]thymidine autoradiographic study. Khachaturian H, et al. **Neuropeptides** 1985 Feb;5(4-6):477-80

Changes in releasability of ACTH and beta-endorphin with chronic stress. Young E, et al. **Neuropeptides** 1985 Feb;5(4-6):545-8

Opiomelanocortins and behavioral adaptation. Bohus B. **Pharmacol Ther** 1984;26(3):417-51 (238 ref.)

Ultrashort-loop positive feedback of corticotropin (ACTH)-releasing factor to enhance ACTH release in stress. Ono N, et al. **Proc Natl Acad Sci USA** 1985 May;82(10):3528-31

Loss of sensitivity to ACTH of adrenocortical cells isolated from maturing domestic fowl. Carsia RV, et al. **Proc Soc Exp Biol Med** 1985 Jul; 179(3):279-82

Increase in plasma ACTH after dopaminergic stimulation in rats. Ježová D, et al. **Psychopharmacology (Berlin)** 1985;85(2):201-3

ACTH-releasing activity of urotensin I and ovine CRF: interactions with arginine vasotocin, isotocin and arginine vasopressin. Fryer J, et al. **Regul Pept** 1985 May;11(1):11-5

[Corticotropin releasing factor] Conte-Devolx B, et al. **Presse Med** 1985 Mar 30;14(13):737-41 (Eng. Abstr.) **(Fre)**

[Effect of an introductory dose of etomidate, methohexital and midazolam on adrenal cortex function before and after ACTH-stimulation] Börner U, et al. **Dtsch Med Wochenschr** 1985 May 10;110(19):750-2 (Eng. Abstr.) **(Ger)**

[Effects of diltiazem on plasma ACTH, beta-ELI and ADH levels during surgery] Kono K, et al. **Masui** 1985 Jan;34(1):18-24 (Eng. Abstr.) **(Jpn)**

[Brain blood supply and beta-endorphin and corticotropin content on exposure to thyroliberin] Mirozoian RS, et al. **Biull Eksp Biol Med** 1985 Mar;99(3):318-20 (Eng. Abstr.) **(Rus)**

[Participation of gamma-aminobutyric acid in regulating corticotropin secretion in rats] Mishunina TM, et al. **Fiziol Zh** 1985 May-Jun; 31(3):321-6 (Eng. Abstr.) **(Rus)**

CORTICOTROPIN RELEASING HORMONE

The distribution of corticotrophin-releasing factor immunoreactivity in various ovine tissues. Kawai K, et al. **Acta Endocrinol (Copenh)** 1985 Apr;108(4):433-9

The effect of nifedipine on CRF-41 and AVP-induced ACTH release in vitro. Murakami K, et al. **Acta Endocrinol (Copenh)** 1985 May; 109(1):32-6

Studies on the site of origin and molecular form of the extrahypothalamic corticotrophin-releasing factor (CRF) in rats. Yasuda N, et al. **Acta Endocrinol (Copenh)** 1985 Jun;109(2):145-52

Corticotropin-releasing factor, sauvagine, and urotensin I: effects on blood flow. Lenz HJ, et al. **Am J Physiol** 1985 Jul;249(1 Pt 2):R85-90

Corticotropin-releasing factor inhibits insulin release from perfused rat pancreas. Moltz JH, et al. **Am J Physiol** 1985 Jun; 248(6 Pt 1):E741-3

Corticotropin-releasing factor: a physiologic regulator of adrenal epinephrine secretion. Brown MR, et al. **Brain Res** 1985 Mar 4; 328(2):355-7

Corticotropin-releasing factor (CRF)-immunoreactive neurons in the mammillary body of the rat. Kovács M, et al. **Cell Tissue Res** 1985; 240(2):455-60

The origin and ultrastructural characteristics of corticotropin-releasing factor (CRF)-immunoreactive nerve fibers in the posterior pituitary of the rat. Lengvári I, et al. **Cell Tissue Res** 1985;240(2):467-71

Studies on peptides. CXXIV. Solution synthesis of the hentetracontapeptide amide corresponding to the entire amino acid sequence of human corticotropin releasing factor (hCRF). Fujii N, et al. **Chem Pharm Bull (Tokyo)** 1984 Dec;32(12):4797-805

Studies on peptides. CXXIII. Preparations of nine peptide fragments for the synthesis of human corticotropin releasing factor (hCRF). Fujii N, et al. **Chem Pharm Bull (Tokyo)** 1984 Dec;32(12):4786-96

Effects of corticotropin-releasing factor (CRF) on aldosterone and 18-hydroxycorticosterone secretion. Maser-Gluth C, et al. **Clin Exp Hypertens [A]** 1984;6(10-11):2097-100

Re-evaluation of 'frontal deafferentation' studies on the regulation of ACTH secretion in the light of CRF immunohistology. Lengvári I, et al. **Endocrinol Exp (Bratisl)** 1985 Mar;19(1):3-9

Effects and pharmacokinetic properties of the rat/human corticotropin-releasing factor in rhesus monkeys. Schürmeyer TH, et al. **Endocrinology** 1985 Jul;117(1):300-6

Corticotropin-releasing factor stimulation of adrenocorticotropin and beta-endorphin release: effects of acute and chronic stress. Young EA, et al. **Endocrinology** 1985 Jul;117(1):23-30

Relationship between pituitary responses to human corticotropin-releasing factor and thyrotropin-releasing hormone in depressives and normal controls. Holsboer F, et al. **Eur J Pharmacol** 1985 Mar 26; 110(1):153-4

Opposite regulation of pro-opiomelanocortin gene transcription by glucocorticoids and CRH. Gagner JP, et al. **Mol Cell Endocrinol** 1985 Apr;40(1):25-32

Co-localization of corticotropin releasing factor and vasopressin mRNA in neurones after adrenalectomy. Wolfson B, et al. **Nature** 1985 May 2-8;315(6014):59-61

Morphometrical analysis of the distribution of corticotrophin releasing factor, glucocorticoid receptor and phenylethanolamine-N-methyltransferase immunoreactive structures in the paraventricular hypothalamic nucleus of the rat. Agnati LF, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):147-52

Anatomical and ontogenetic studies of the human paraventriculo-infundibular corticoliberin system. Bresson JL, et al. **Neuroscience** 1985 Apr;14(4):1077-90

Long-term suspension culture of isolated hypothalamic nuclei of the rat: morphological differentiation and release of substances influencing corticotropin and growth hormone secretion. Gyévai A, et al. **Neuroscience** 1985 Feb;14(2):519-33

Distribution of CRF- and tyrosine hydroxylase-immunoreactive neurons in the brainstem of the domestic fowl (Gallus domesticus). Knigge KM, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):97-101

Ultrashort-loop positive feedback of corticotropin (ACTH)-releasing factor to enhance ACTH release in stress. Ono N, et al. **Proc Natl Acad Sci USA** 1985 May;82(10):3528-31

Interaction of arginine vasopressin and corticotropin releasing factor demonstrated with an improved bioassay. Graf MV, et al. **Proc Soc Exp Biol Med** 1985 Jul;179(3):303-8

ACTH-releasing activity of urotensin I and ovine CRF: interactions with arginine vasotocin, isotocin and arginine vasopressin. Fryer J, et al. **Regul Pept** 1985 May;11(1):11-5

[Corticotropin releasing factor] Conte-Devolx B, et al. **Presse Med** 1985 Mar 30;14(13):737-41 (Eng. Abstr.) **(Fre)**

DANSYL COMPOUNDS

pH dependence of phosphate transport across the red blood cell membrane after modification by dansyl chloride. Berghout A, et al. **Biochim Biophys Acta** 1985 May 14;815(2):281-6

Binding of N-dansylgalactosamine to the lectin from Erythrina cristagalli as followed by stopped-flow and pressure-jump relaxation kinetics. De Boeck H, et al. **Eur J Biochem** 1985 May 15;149(1):141-5

New high-performance liquid chromatography system for the separation of biogenic amines as their Dns derivatives. Hayman AR, et al. **J Chromatogr** 1985 Jun 7;325(2):462-6

DELUSIONS

Plasma catecholamines and ECT. Khan A, et al. **Biol Psychiatry** 1985 Jul;20(7):799-804

DEMENTIA

Rational drug treatment of dementia? [editorial] Byrne J, et al. **Br Med J [Clin Res]** 1985 Jun 22;290(6485):1845-6

DEPRESSION

Plasma tryptophan, age and depression. Phipps DA, et al. **Age Ageing** 1985 Mar;14(2):71-5

Biochemical theories of schizophrenia and depression. Hollister LE. **Ann Acad Med Singapore** 1985 Jan;14(1):76-80

Brief review of published alprazolam clinical studies. Straw RN. **Br J Clin Pharmacol** 1985;19 Suppl 1:57S-59S (22 ref.)

DEPRESSIVE DISORDER

Qualitative and quantitative analysis of the action of typical and atypical antidepressants in the experimental animal. Kozlovskaya MM, et al. **Ann Ist Super Sanita** 1984;20(1):73-7

Can lithium carbonate prolong the antidepressant effect of sleep deprivation? [letter] Baxter LR Jr. **Arch Gen Psychiatry** 1985 Jun; 42(6):635

Internight variability of REM latency in major depression: implications for the use of REM latency as a biological correlate. Ansseau M, et al. **Biol Psychiatry** 1985 May;20(5):489-505

Resting metabolic rate is reduced in patients treated with antidepressants. Fernstrom MH, et al. **Biol Psychiatry** 1985 Jun;20(6):692-5

Animal models of depression: parallels and correlates to severe depression in humans. Jesberger JA, et al. **Biol Psychiatry** 1985 Jul; 20(7):764-84

Plasma catecholamines and ECT. Khan A, et al. **Biol Psychiatry** 1985 Jul;20(7):799-804

Lack of efficacy of estrogen supplementation to imipramine in resistant female depressives. Shapira B, et al. **Biol Psychiatry** 1985 May; 20(5):576-9

Platelet monoamine oxidase inhibition by deprenyl and tranylcypromine: implications for clinical use. Simpson GM, et al. **Biol Psychiatry** 1985 Jun;20(6):684-7

Factor analytic derivation of the MHPG/NM ratio: implications for studying the link between physical fitness and depression. Sothmann MS, et al. **Biol Psychiatry** 1985 May;20(5):579-83

Antidepressant properties of the triazolobenzodiazepines alprazolam and adinazolam: studies on the olfactory bulbectomized rat model of depression. O'Connor WT, et al. **Br J Clin Pharmacol** 1985; 19 Suppl 1:49S-56S

Relationship between pituitary responses to human corticotropin-releasing factor and thyrotropin-releasing hormone in depressives and normal controls. Holsboer F, et al. **Eur J Pharmacol** 1985 Mar 26; 110(1):153-4

A clinical and pharmacological study of the antidepressant activity of viloxazine in adult and elderly patients. Tosca P, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 May;23(5):270-3

Neuroticism and personality disorder in depression. Davidson J, et al. **J Affective Disord** 1985 Mar-Apr;8(2):177-82

The influence of mania and depression on the pharmacokinetics of lithium. A longitudinal single-case study. Kukopoulos A, et al. **J Affective Disord** 1985 Mar-Apr;8(2):159-66

Plasma nortriptyline and clinical response in depression. Murphy GE, et al. **J Affective Disord** 1985 Mar-Apr;8(2):123-9

Drug response as a predictor of transmission of non-bipolar major depression within families. Prusoff BA, et al. **J Affective Disord** 1985 Mar-Apr;8(2):171-6

Imipramine metabolism in recurrent depressive episodes. Tollefson G, et al. **J Affective Disord** 1985 Mar-Apr;8(2):183-6

Combined MAOI, TCA, and direct stimulant therapy of treatment-resistant depression. Feighner JP, et al. **J Clin Psychiatry** 1985 Jun;46(6):206-9

Trimipramine and maprotiline: antidepressant, anxiolytic, and cardiotoxic comparison. Pecknold JC, et al. **J Clin Psychiatry** 1985 May; 46(5):166-71

Thyroxine binding and TSH in recurrent depressive episodes. Tollefson G, et al. **J Clin Psychiatry** 1985 Jul;46(7):267-72

Peripheral edema associated with trazodone: a report of ten cases. Barnett J, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):161-4

Child and adolescent nortriptyline single dose kinetics predict steady state plasma levels and suggested dose: preliminary data. Geller B, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):154-8

Amitriptyline and hydroxylated metabolite plasma levels in depressed outpatients. Robinson DS, et al. **J Clin Psychopharmacol** 1985 Apr; 5(2):83-8

Monoamine oxidase inhibitors in the treatment of atypical depression. Zisook S, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):131-7

Stress and immunomodulation: the role of depression and neuroendocrine function. Stein M, et al. **J Immunol** 1985 Aug; 135(2 Suppl):827s-833s

Comparison of limbitrol (chlordiazepoxide/amitriptyline) and amitriptyline alone as a single night-time dose for the treatment of depression with anxiety. James RT, et al. **J Int Med Res** 1985; 13(2):84-7

Two cases of obsessive-compulsive disorder with depression responsive to trazodone. Baxter LR Jr. **J Nerv Ment Dis** 1985 Jul;173(7):432-3

Understanding and treatment of childhood depression. Aylward GP. **J Pediatr** 1985 Jul;107(1):1-9

Enhanced signal transduction by adenylate cyclase in platelet membranes of patients showing antidepressant responses to alprazolam: preliminary data. Mooney JJ, et al. **J Psychiatr Res** 1985;19(1):65-75

Cholinomimetic drug RS 86, REM sleep, and depression [letter] Berger M, et al. **Lancet** 1985 Jun 15;1(8442):1385-6

Mianserin versus amitriptyline for depression: a double-blind 6-week trial. Rabkin JG, et al. **Neuropsychobiology** 1984;12(4):224-8

KUSTA (Kurz-Skala Stimmung/Aktivierung): a daily self-rating scale for depressive patients. Wendt G, et al. **Pharmacopsychiatry** 1985 Jan; 18(1):118-22

Studies on the locus coeruleus system in an animal model for antidepressive activity. Kostowski W, et al. **Pol J Pharmacol Pharm** 1984 Sep-Oct;36(5):523-30

The olfactory bulbectomized rat as a model of depression. Leonard BE. **Pol J Pharmacol Pharm** 1984 Sep-Oct;36(5):561-9 (30 ref.)

Trazodone in endogenous depressed patients: a negative report and a critical evaluation of the pertaining literature. Klein HE, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(2):173-86

Delta-sleep inducing peptide in cerebrospinal fluid from schizophrenics, depressives and healthy volunteers. Lindström LH, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(1):83-90

The cortisol response to desipramine in endogenous depressives and normal controls: preliminary findings. Asnis GM, et al. **Psychiatry Res** 1985 Mar;14(3):225-33

Elevated plasma homovanillic acid in depressed females with melancholia and psychosis. Devanand DP, et al. **Psychiatry Res** 1985 May; 15(1):1-4

The effect of clorgyline on noradrenergic function. Ross RJ, et al. **Psychopharmacology (Berlin)** 1985;85(2):227-30

Effects of carbamazepine on cerebrospinal fluid somatostatin. Rubinow DR, et al. **Psychopharmacology (Berlin)** 1985;85(2):210-3

'Pseudo-allergy': treatment with an MAO inhibitor. Ulwelling W. **Psychosomatics** 1985 Jun;26(6):535-6

A preliminary report on anti-depressant therapy and its effects on hope and immunity. Udelman DL, et al. **Soc Sci Med** 1985; 20(10):1069-72

[Alprazolam (Tafil). A new benzodiazepine-with a new action profile?] Rasmussen SB, et al. **Ugeskr Laeger** 1985 Apr 29;147(18):1495-7 **(Dan)**

[Comparison of various tools for evaluating depression apropos of a study on Athymil 30 mg] Lempérière T, et al. **Ann Med Psychol (Paris)** 1984 Nov;142(9):1206-14 **(Fre)**

[Selective study of sulfate and glucuronide conjugates of urinary MHPG in nervous depression. Peripheral and central influences] Peyrin L, et al. **Encephale** 1985 Jan-Feb;11(1):19-24 (Eng. Abstr.) **(Fre)**

[Depressive states and biological markers] Boyer P. **Rev Prat** 1985 May 11;35(27):1627-32 (Eng. Abstr.) **(Fre)**

[Effect of preventive administration of lithium carbonate on serum concentrations of various pituitary and peripheral hormones in patients with endogenous depression] Horodnicki JM, et al. **Psychiatr Pol** 1984 Jul-Aug;18(4):319-25 (Eng. Abstr.) **(Pol)**

[Various aspects of the differential therapy of circular depressions] Prokhorova IS. **Zh Nevropatol Psikhiatr** 1985;85(4):570-4 (Eng. Abstr.) **(Rus)**

[Sleep deprivation as a method of treating endogenous depression] Vovin RIa, et al. **Zh Nevropatol Psikhiatr** 1985;85(4):560-5 (Eng. Abstr.) **(Rus)**

DESIPRAMINE

Comparison of the effects of chronic administration of ciclazindol and desipramine on pupillary responses to tyramine, methoxamine and pilocarpine in healthy volunteers. Kerr FA, et al. **Br J Clin Pharmacol** 1985 May;19(5):639-47

Effect of chronic desipramine treatment on adrenoceptor modulation of [3H]dopamine release from rat nucleus accumbens slices. Nurse B, et al. **Brain Res** 1985 May 20;334(2):235-42

Effect of chronic reserpine and desmethylimipramine treatment on CRF-like immunoreactivity of discrete brain areas of rat. Tizabi Y, et al. **Brain Res** 1985 Jun 3;335(2):389-91

Why is amitriptyline much weaker than desipramine at decreasing beta-adrenoceptor numbers? Wise H, et al. **Eur J Pharmacol** 1985 Mar 26;110(1):137-41

Tricyclic antidepressants antagonize prostaglandin (PG) E2-induced contractions of the guinea pig ileum and hypomotility in the mouse. Tayo FM. **Experientia** 1985 Apr 15;41(4):474-6

Interethnic dissociation between debrisoquine and desipramine hydroxylation. Rudorfer MV, et al. **J Clin Psychopharmacol** 1985 Apr; 5(2):89-92

Inhibition of the retrograde axonal transport of acetylcholinesterase by the anti-calmodulin agents amitriptyline and desipramine. Tiberi M, et al. **J Neurobiol** 1985 May;16(3):245-8

Cardiovascular effects of desipramine in children and adolescents with attention deficit disorder. Biederman J, et al. **J Pediatr** 1985 Jun; 106(6):1017-20

Down-regulation of beta-adrenoceptors in rat cortex by repeated administration of desipramine, electroconvulsive shock and clenbuterol requires 5-HT neurones but not 5-HT. Nimgaonkar VL, et al. **Neuropharmacology** 1985 Apr;24(4):279-83

The effect of prolonged treatment with tricyclic antidepressants on the actions of 5-hydroxytryptamine in the hippocampal slice of the rat. Rowan MJ, et al. **Neuropharmacology** 1985 Feb;24(2):131-7

Drug interactions and vasoconstrictors used in local anesthetic solutions. Yagiela JA, et al. **Oral Surg Oral Med Oral Pathol** 1985 Jun; 59(6):565-71

Studies on the locus coeruleus system in an animal model for antidepressive activity. Kostowski W, et al. **Pol J Pharmacol Pharm** 1984 Sep-Oct;36(5):523-30

The cortisol response to desipramine in endogenous depressives and normal controls: preliminary findings. Asnis GM, et al. **Psychiatry Res** 1985 Mar;14(3):225-33

Dose-dependent growth hormone, prolactin and cortisol stimulation after i.v. administration of desimipramine in human subjects. Laakmann G, et al. **Psychoneuroendocrinology** 1985;10(1):83-93

Paradoxical sleep deprivation and the immobility response in the rat: effects of desipramine and phentolamine. van Luijtelaar EL, et al. **Sleep** 1985;8(1):49-55

DESOXYCORTICOSTERONE

Effect of hydrocortisone and desoxycorticosterone on some reductases, esterases and synthetases. Tancheva L, et al. **Acta Physiol Pharmacol Bulg** 1984;10(4):59-63

Mineralocorticoid regulation of apical cell membrane Na+ and K+ transport of the cortical collecting duct. Sansom SC, et al. **Am J Physiol** 1985 Jun;248(6 Pt 2):F858-68

Lack of renal effects of DOCA, ACTH, spironolactone, and angiotensin II in Squalus acanthias. Churchill PC, et al. **J Exp Zool** 1985 Apr; 234(1):17-22

Sodium-dependent modulation of the renal Na-K-ATPase: influence of mineralocorticoids on the cortical collecting duct. O'Neil RG, et al. **J Membr Biol** 1985;85(2):169-79

Effects of angiotensin or carbachol on sodium intake and excretion in adrenalectomized or deoxycorticosterone-treated rats. Fitzsimons JT, et al. **J Physiol (Lond)** 1985 Feb;359:447-58

Comparison of the distribution kinetics and metabolism to acid end-products of corticosterone and 11-deoxycorticosterone in BALB/c mice. Marandici A, et al. **J Steroid Biochem** 1985 Apr;22(4):539-45

DEXTROAMPHETAMINE

Effects of some motion sickness suppressants on static and dynamic tracking performance. Schroeder DJ, et al. **Aviat Space Environ Med** 1985 Apr;56(4):344-50

Association of the mesencephalic locomotor region with locomotor activity induced by injections of amphetamine into the nucleus accumbens. Brudzyński SM, et al. **Brain Res** 1985 May 13; 334(1):77-84

6-OHDA lesions of the ventral tegmental area block morphine-induced but not amphetamine-induced facilitation of self-stimulation. Hand TH, et al. **Brain Res** 1985 Mar 4;328(2):233-41

Nigral reticulata neurons: potentiation of responsiveness to amphetamine with long-term treatment. Kamata K, et al. **Brain Res** 1985 Apr 15; 332(1):188-93

Frequency-related, bidirectional limbic responses to cocaine: comparisons with amphetamine and lidocaine. Lesse H, et al. **Brain Res** 1985 May 27;335(1):21-31

Effects of D- and L-amphetamine on dopamine metabolism and ascorbic acid levels in nucleus accumbens and olfactory tubercle as studied by in vivo differential pulse voltammetry. Louilot A, et al. **Brain Res** 1985 Jun 17;336(2):253-63

An investigation of amphetamine-induced release of 5-HT from rat hippocampal slices. Balfour DJ, et al. **Eur J Pharmacol** 1985 Mar 12; 109(3):395-9

Combined MAOI, TCA, and direct stimulant therapy of treatment-resistant depression. Feighner JP, et al. **J Clin Psychiatry** 1985 Jun;46(6):206-9

Amphetamine induced release of endogenous dopamine in vitro is not reduced following pretreatment with reserpine. Niddam R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):123-7

The effects of d-amphetamine, chlordiazepoxide and alpha-flupenthixol on food-reinforced tracking of a visual stimulus by rats. Evenden JL, et al. **Psychopharmacology (Berlin)** 1985;85(3):361-6

The discriminative stimulus properties and detection thresholds of intracranial self-stimulation: effects of d-amphetamine, morphine, and haloperidol. Schaefer GJ, et al. **Psychopharmacology (Berlin)** 1985; 85(3):289-94

DIAZEPAM

Foot shock-induced decrease of low affinity GABA receptors in the rat brain: antagonism by diazepam. Concas A, et al. **Ann Ist Super Sanita** 1984;20(1):53-6

The influence of cyclobarbital and diazepam on drug metabolism in vitro and their binding to cytochrome P-450. Wierzba W, et al. **Biomed Biochim Acta** 1984;43(12):1425-30

The effects of age and smoking on the plasma protein binding of lignocaine and diazepam. Davis D, et al. **Br J Clin Pharmacol** 1985 Feb; 19(2):261-5

A double-blind comparison of alprazolam, diazepam and placebo in the treatment of anxious out-patients. Davison K, et al. **Br J Clin Pharmacol** 1985;19 Suppl 1:37S-43S

Controlled study of withdrawal symptoms and rebound anxiety after six week course of diazepam for generalised anxiety. Power KG, et al. **Br Med J [Clin Res]** 1985 Apr 27;290(6477):1246-8

Blockade of the diazepam-induced increase in rat striatal acetylcholine content by the specific benzodiazepine antagonists ethyl-beta-carboline-3-carboxylate and Ro 15-1788. Kolasa K, et al. **Brain Res** 1985 Jun 17;336(2):342-5

Prenatal exposure to diazepam results in enduring reductions in brain receptors and deep slow wave sleep. Livezey GT, et al. **Brain Res** 1985 May 20;334(2):361-5

Pre-natal administration of diazepam improves radial maze learning in mice. Benton D, et al. **Comp Biochem Physiol [C]** 1985;80(2):273-5

Intramuscular bioavailability of chlorazepate as compared to diazepam. Bertler A, et al. **Eur J Clin Pharmacol** 1985;28(2):229-30

Pharmacological evidence that the non-neuronal diazepam binding site in primary cultures of glial cells is associated with a calcium channel. Bender AS, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):287-8

Extraction, separation, and detections of 14C-diazepam and 14C-metabolites from brain tissue of mature and old rats. Komiskey HL, et al. **J Anal Toxicol** 1985 May-Jun;9(3):131-3

Increased sensitivity of the elderly to the central depressant effects of diazepam. Pomara N, et al. **J Clin Psychiatry** 1985 May;46(5):185-7

3-Amino-beta-carboline derivatives and the benzodiazepine receptor. Synthesis of a selective antagonist of the sedative action of diazepam. Dodd RH, et al. **J Med Chem** 1985 Jun;28(6):824-8

Some long-lasting neurochemical effects of prenatal or early postnatal exposure to diazepam. Frieder B, et al. **J Neurochem** 1985 Jul; 45(1):37-42

Solubilization by cosolvents III: Diazepam and benzocaine in binary solvents. Rubino JT, et al. **J Parenter Sci Technol** 1985 May-Jun; 39(3):106-11

Responsibilities of prescribing. Avery JK. **J Tenn Med Assoc** 1985 May; 78(5):297

Inhibitory effect on 3H-diazepam binding and potentiating action on GABA of ethyl loflazepate, a new minor tranquilizer. Sakai Y, et al. **Jpn J Pharmacol** 1985 Apr;37(4):373-9

Differential mediation of the anticonvulsant effects of carbamazepine and diazepam. Weiss SR, et al. **Life Sci** 1985 Jun 24;36(25):2413-9

Patterns of diazepam prescribing in primary care: a case control study. Mulvihill MN, et al. **Mt Sinai J Med (NY)** 1985 Apr;52(4):276-80

The effects of benzodiazepines on spinal homosynaptic depression. Davies MF, et al. **Neuropharmacology** 1985 Apr;24(4):301-7

Evidence that 2-phenylpyrazolo[4,3-c]-quinolin-3(5H)-one antagonises pharmacological, electrophysiological and biochemical effects of diazepam in rats. Santi M, et al. **Neuropharmacology** 1985 Feb; 24(2):99-105

Evidence that tolerance develops to the anxiolytic effect of diazepam in rats. Treit D. **Pharmacol Biochem Behav** 1985 Mar;22(3):383-7

Role of neurotransmitters and teratogens on palate development. Zimmerman EF, et al. **Prog Clin Biol Res** 1985;163C:405-8

The effects of intravenous diazepam and hyoscine upon human memory. Frith CD, et al. **Q J Exp Psychol [A]** 1984 Feb;36(1):133-44

Concentration independent accumulation of diazepam by rat liver slices. Effect of human serum albumin. Blaese U, et al. **Res Commun Chem Pathol Pharmacol** 1985 Feb;47(2):313-6

Generic Valiums clear another hurdle at FDA [news] Sun M. **Science** 1985 Jul 26;229(4711):369

Benzodiazepines inhibit human platelet activation: comparison of the mechanism of antiplatelet actions of flurazepam and diazepam. Romstedt K, et al. **Thromb Res** 1985 May 15;38(4):361-74

[Intravenous sedation before endoscopic interventions. Comparative study of lormetazepam and diazepam in oil] Tolksdorf W, et al. **Fortschr Med** 1985 Mar 7;103(9):249-52 (Eng. Abstr.) **(Ger)**

[Harman-induced changes in the anxiolytic effect of diazepam] Zin'kovskaia LIa, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):21-3 (Eng. Abstr.) **(Rus)**

[Effect of sodium valproate on brain levels of diazepam and N-desmethyldiazepam in the rat] Gómez Luque A, et al. **Arch Farmacol Toxicol** 1985 Apr;11(1):13-8 (Eng. Abstr.) **(Spa)**

DIBENZAZEPINES

Trimipramine and maprotiline: antidepressant, anxiolytic, and cardiotoxic comparison. Pecknold JC, et al. **J Clin Psychiatry** 1985 May; 46(5):166-71

Mianserin versus amitriptyline for depression: a double-blind 6-week trial. Rabkin JG, et al. **Neuropsychobiology** 1984;12(4):224-8

Mianserin [letter] Edwards IR. **NZ Med J** 1985 May 8;98(778):350

Effects of some dibenzo-azepines on suppressed and nonsuppressed behavior of squirrel monkeys. Spealman RD. **Psychopharmacology (Berlin)** 1985;85(2):129-32

Differential alteration of striatal D-1 and D-2 receptors induced by the long-term administration of haloperidol, sulpiride or clozapine to rats. Jenner P, et al. **Psychopharmacology [Suppl]** 1985;2:174-81

[Comparison of various tools for evaluating depression apropos of a study on Athymil 30 mg] Lempérière T, et al. **Ann Med Psychol (Paris)** 1984 Nov;142(9):1206-14 **(Fre)**

[Immunoallergic febrile reaction with hypereosinophilia after ingestion of metapramine (letter)] Gentric A, et al. **Presse Med** 1985 Jun 8; 14(23):1290 **(Fre)**

DIBENZOTHIEPINS

Possible relationship between antimanic effect and activity of zotepine to 5HT1 receptor. Harada T, et al. **Folia Psychiatr Neurol Jpn** 1984; 38(4):473-80

Delayed gastric emptying with dothiepin. Woodhouse KW, et al. **Hum Toxicol** 1985 Jan;4(1):67-70

Decreased 5-HT2 but not 5-HT1 receptor binding in cortex of rat after chronic administration of dothiepin. Application of the Woolf plot to analysis of binding parameters. Diggory GL, et al. **Neuropharmacology** 1985 Apr;24(4):275-8

DIBENZOXAZEPINES

Pharmacokinetics of amoxapine and its active metabolites. Calvo B, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Apr;23(4):180-5

Amoxapine-associated acute renal failure [letter] Chu CC, et al. **South Med J** 1985 Jun;78(6):761

DIETHYLAMINES

Dietary phenolics and betel nut extracts as modifiers of N-nitrosation in rat and man. Stich HF, et al. **IARC Sci Publ** 1984;(57):213-22

Metabolism of N-nitrodialkylamines. Suzuki E, et al. **IARC Sci Publ** 1984; (57):485-90

[Gas-chromatographic analysis of beta-diethylaminoethylchloride and beta-diethylaminoethylacetate ether in the air of work areas] Bake MIa. **Gig Tr Prof Zabol** 1985 Feb;(2):54-6 **(Rus)**

DIIODOTYROSINE

[Ultrastructural changes in thyrocytes exposed to the antithyroid preparations betazin and diiodotyrosine] Trunov VI, et al. **Tsitol Genet** 1985 Jan-Feb;19(1):13-7 (Eng. Abstr.) **(Rus)**

DISCRIMINATION (PSYCHOLOGY)

Effects of selective dopamine receptor agonists in rats trained to discriminate apomorphine from saline. Woolverton WL, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):577-81

The discriminative stimulus properties and detection thresholds of intracranial self-stimulation: effects of d-amphetamine, morphine, and haloperidol. Schaefer GJ, et al. **Psychopharmacology (Berlin)** 1985; 85(3):289-94

DISCRIMINATION LEARNING

Effects of psychotropic drugs on discrimination conditioning in olfactory bulbectomized rats. Gomita Y, et al. **Pharmacol Biochem Behav** 1985 May;22(5):717-22

DOPA

Simultaneous assay of 3,4-dihydroxyphenylalanine, catecholamines and O-methylated metabolites in human plasma using high-performance liquid chromatography. Ishimitsu T, et al. **J Chromatogr** 1985 Feb 8; 337(2):239-48

[Enzymatic synthesis of 3,4-dihydroxyphenyl-L-alanine by free and immobilized Citrobacter freundii cells] Voivodov KI, et al. **Prikl Biokhim Mikrobiol** 1985 Mar-Apr;21(2):161-6 (Eng. Abstr.) **(Rus)**

DOPAMINE

Catecholamine microfluorometry of nigral perikarya and tyrosine hydroxylase assay in some telencephalic structures of rats exposed to different behavioral situations. Divac I, et al. **Acta Neurobiol Exp (Warsz)** 1984;44(6):262-72

Growth hormone releasing factor (GRF) and dopamine coexist in hypothalamic arcuate neurons. Meister B, et al. **Acta Physiol Scand** 1985 May;124(1):133-6

3H-dopamine clearance from the intravascular compartment of the maternal and fetal rhesus monkey. Phillippe M, et al. **Am J Obstet Gynecol** 1985 Jul 1;152(5):599-601

Clearance of 3H-dopamine from the amniotic fluid in the rhesus monkey. Phillippe M, et al. **Am J Obstet Gynecol** 1985 Jul 1;152(5):601-2

Central effects of angiotensin II and dopamine in sodium-depleted sheep. Huang BS, et al. **Am J Physiol** 1985 May;248(5 Pt 2):R541-8

The renal effects of dopamine [letter] Cramolini GM. **Anesthesiology** 1985 Jun;62(6):844

Physiologic and pharmacologic characterization of a novel group of substantia nigra zona reticulata neurons involved in striatal dopamine regulation. Chan SH. **Ann Acad Med Singapore** 1985 Jan;14(1):153-7

On the role of dopamine receptors in aldosterone secretion. Frisina N, et al. **Ann Endocrinol (Paris)** 1984;45(6):387-91

Mechanisms involved in the release of dopamine from the tuberoinfundibular system in vitro. Amoroso S, et al. **Ann Ist Super Sanita** 1984;20(1):109-11

Effect of dopamine on the threshold of the voltage-dependent ionic channels in the rat brain. Bernardi G, et al. **Ann Ist Super Sanita** 1984; 20(1):1-4

6R-L-erythro-5,6,7,8-tetrahydrobiopterin as a regulator of dopamine and serotonin biosynthesis in the rat brain. Miwa S, et al. **Arch Biochem Biophys** 1985 May 15;239(1):234-41

Asymmetry in the effects of unilateral 6-OHDA lesions on eating and drinking evoked by hypothalamic stimulation. Mittleman G, et al. **Behav Brain Res** 1985 May;15(3):263-7

Catecholamine-blocking drugs injected at sites of amine accumulation reverse catecholamine degeneration associated deficits. Willis GL, et al. **Behav Brain Res** 1985 Apr;15(2):101-6

SCH 23390 may alter dopamine-mediated motor behaviour via striatal D-1 receptors. Boyce S, et al. **Biochem Pharmacol** 1985 May 15; 34(10):1665-9

Binding characteristics of the dopamine uptake inhibitor [3H]nomifensine to striatal membranes. Dubocovich ML, et al. **Biochem Pharmacol** 1985 Apr 15;34(8):1137-44

BIBLIOGRAPHY

DOPAMINE

Selective increase in dopamine metabolism in the prefrontal cortex by the anxiogenic beta-carboline FG 7142. Tam SY, et al. **Biochem Pharmacol** 1985 May 1;34(9):1595-8

Effect of chronic postnatal hypoxia on dopamine uptake by synaptosomes from striatum of adult rats. Ihle W, et al. **Biomed Biochim Acta** 1985; 44(3):433-7

Dopamine-stimulated fucosylation of brain proteins in vitro is not inhibited by puromycin. Lössner B, et al. **Biomed Biochim Acta** 1985; 44(3):465-73

Ethanol preference behaviour and dopamine release in the rat. Schmidt J, et al. **Biomed Biochim Acta** 1984;43(12):1431-4

Dopamine autoreceptors and the effects of drugs on locomotion and dopamine synthesis. Brown F, et al. **Br J Pharmacol** 1985 Apr; 84(4):853-60

Rapid desensitization of presynaptic dopamine autoreceptors during exposure to exogenous dopamine. Arbilla S, et al. **Brain Res** 1985 Jun 24;337(1):11-7

Subchronic administration of GABAergic agonists elevates [3H]GABA binding and produces tolerance in striatal dopamine catabolism. Beart PM, et al. **Brain Res** 1985 May 27;335(1):169-73

Effects of inhibitors of Na+,K+-ATPase on the membrane potentials and neurotransmitter efflux in rat brain slices. Brosemer RW. **Brain Res** 1985 May 13;334(1):125-37

Association of the mesencephalic locomotor region with locomotor activity induced by injections of amphetamine into the nucleus accumbens. Brudzyński SM, et al **Brain Res** 1985 May 13; 334(1):77-84

Dopaminergic mechanisms in subthalamic nucleus of rat: analysis using horseradish peroxidase and microiontophoresis. Campbell GA, et al. **Brain Res** 1985 May 6;333(2):261-70

Involvement of nigrostriatal dopamine neurons in the contraversive rotational behavior evoked by electrical stimulation of the lateral hypothalamus. Castañeda E, et al. **Brain Res** 1985 Feb 18; 327(1-2):143-51

Excitatory and inhibitory effects of dopamine on synaptic transmission in the rat olfactory cortex slice. Collins GG, et al. **Brain Res** 1985 May 6;333(2):237-45

Topographical analysis of nucleus accumbens sites at which cholecystokinin potentiates dopamine-induced hyperlocomotion in the rat. Crawley JN, et al. **Brain Res** 1985 Jun 3;335(2):337-41

The formation of deaminated metabolites of dopamine in the locus coeruleus depends upon noradrenergic neuronal activity. Curet O, et al. **Brain Res** 1985 Jun 3;335(2):297-301

The hypothalamohypophyseal system in vitro: electrophysiology of the pars intermedia and evidence for both excitatory and inhibitory inputs. Davis MD, et al. **Brain Res** 1985 May 13;334(1):97-104

The prefrontal 'cortex' in the pigeon. Biochemical evidence. Divac I, et al. **Brain Res** 1985 Apr 22;332(2):365-8

Low doses of apomorphine elicit two opposing influences on dopamine cell electrophysiology. Grace AA, et al. **Brain Res** 1985 May 6; 333(2):285-98

Opposing effects of striatonigral feedback pathways on midbrain dopamine cell activity. Grace AA, et al. **Brain Res** 1985 May 6;333(2):271-84

6-OHDA lesions of the ventral tegmental area block morphine-induced but not amphetamine-induced facilitation of self-stimulation. Hand TH, et al. **Brain Res** 1985 Mar 4;328(2):233-41

Effects of D- and L-amphetamine on dopamine metabolism and ascorbic acid levels in nucleus accumbens and olfactory tubercle as studied by in vivo differential pulse voltammetry. Louilot A, et al. **Brain Res** 1985 Jun 17;336(2):253-63

Quantification of lesion-induced dopaminergic supersensitivity using the rotational model in the mouse. Mandel RJ, et al. **Brain Res** 1985 Mar 25;330(2):358-63

Effect of chronic desipramine treatment on adrenoceptor modulation of [3H]dopamine release from rat nucleus accumbens slices. Nurse B, et al. **Brain Res** 1985 May 20;334(2):235-42

Possible interactions between dynorphin and dopaminergic systems in rat basal ganglia and substantia nigra. Quirion R, et al. **Brain Res** 1985 Apr 8;331(2):358-62

Potential changes of frog afferent terminals in response to dopamine. Ryan GP, et al. **Brain Res** 1985 Mar 4;328(2):283-90

Dopamine depletion in a striatal subregion disrupts performance of a skilled motor task in the rat. Sabol KE, et al. **Brain Res** 1985 May 27;335(1):33-43

Spatial distribution of dopamine, methotrexate and antipyrine during continuous intracerebral microperfusion. Sendelbeck SL, et al. **Brain Res** 1985 Mar 4;328(2):251-8

The distribution of monoaminergic cells and fibers in a periventricular preoptic nucleus involved in the control of gonadotropin release: immunohistochemical evidence for a dopaminergic sexual dimorphism. Simerly RB, et al. **Brain Res** 1985 Mar 18;330(1):55-64

Reactive capacity: a sensitive behavioral marker of movement initiation and nigrostriatal dopamine function. Spirduso WW, et al. **Brain Res** 1985 May 27;335(1):45-54

On the origin of dopamine and its metabolite in predominantly noradrenergic innervated brain areas. Westerink BH, et al. **Brain Res** 1985 Mar 18;330(1):164-6

Dopamine production by isolated glomeruli and tubules from rat kidneys. Baines AD, et al. **Can J Physiol Pharmacol** 1985 Feb;63(2):155-8

Estradiol increases dopamine turnover in intermediate and posterior pituitary lobes of ovariectomized rats. Saavedra JM, et al. **Cell Mol Neurobiol** 1984 Dec;4(4):397-402

Study of the interrelationship between dopaminergic activity and potassium ion. Matsuda S, et al. **Clin Exp Hypertens [A]** 1984; 6(12):2249-61

Evaluation of the central dopaminergic activity in gestational hyperprolactinaemia by means of the electroretinographic technique. De Luca Brunori I, et al. **Clin Exp Obstet Gynecol** 1985; 12(1-2):13-5

Effect of secretagogues on pancreatic exocrine secretion in the monkey and the dog. Iwatsuki K, et al. **Clin Exp Pharmacol Physiol** 1985 Jan-Feb;12(1):67-72

Dopamine: receptors and clinical applications. Goldberg LI. **Clin Physiol Biochem** 1985;3(2-3):120-6 (33 ref.)

Norepinephrine alone versus norepinephrine plus low-dose dopamine: enhanced renal blood flow with combination pressor therapy. Schaer GL, et al. **Crit Care Med** 1985 Jun;13(6):492-6

Effects of 6-hydroxydopamine-induced catecholamine depletion on shock-precipitated wall climbing of infant rat pups. Emerich DF, et al. **Dev Psychobiol** 1985 May;18(3):215-27

Strain differences in brain biogenic amines concentration in rats with different resistance to emotional stress. Sudakov KV, et al. **Endocrinol Exp (Bratisl)** 1985 Mar;19(1):39-45

In vitro and in vivo antagonistic regulation by estradiol and progesterone of the rat pituitary domperidone binding sites: correlation with ovarian steroid regulation of the dopaminergic inhibition of prolactin secretion in vitro. Bression D, et al. **Endocrinology** 1985 May;116(5):1905-11

Prolactin metabolic clearance and resistance to dopaminergic suppression in acute uremia. McKenna TM, et al. **Endocrinology** 1985 May; 116(5):2003-7

Rapid effects of hyperprolactinemia on basal prolactin secretion and dopamine turnover in the medial and lateral median eminence. Selmanoff M. **Endocrinology** 1985 May;116(5):1943-52

The effect of dopamine administration on the activity of the renin-angiotensin-aldosterone system in sick preterm infants. Sulyok E, et al. **Eur J Pediatr** 1985 Jan;143(3):191-3

Striatal synaptosomal dopamine synthesis: evidence against direct regulation by an autoreceptor mechanism. Compton DR, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):157-62

Magnesium ions reveal nanomolar potency of dopamine at [3H]spiperone labelled D-2 receptors in rat corpus striatum. De Vries DJ, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):417-9

Dopamine preferentially stimulates postsynaptic alpha 2-adrenoceptors in the femoral vascular bed, but alpha 1-adrenoceptors in the renal vascular bed of the anaesthetised dog. Duval N, et al. **Eur J Pharmacol** 1985 Feb 5;108(3):265-72

Pharmacological changes in dopaminergic systems induced by long-term administration of amantadine. Gianutsos G, et al. **Eur J Pharmacol** 1985 Apr 16;110(3):357-61

Phencyclidine-induced inhibition of rat prolactin secretion: increased portal blood dopamine. Meltzer HY, et al. **Eur J Pharmacol** 1985 Mar 26;110(1):143-6

Electrochemical, pharmacological and electrophysiological evidence of rapid dopamine release and removal in the rat caudate nucleus following electrical stimulation of the median forebrain bundle. Millar J, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):341-8

Role of the dopamine uptake carrier in the neurochemical response to methamphetamine: effects of amfonelic acid. Schmidt CJ, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):73-80

Differences in dopamine- and noradrenaline-induced amylase release from the rat parotid gland. Sundström S, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):355-61

Reduced sensitivity of synaptosomal dopamine autoreceptors following increase in synaptosomal dopamine synthesis. Tissari AH. **Eur J Pharmacol** 1985 Mar 12;109(3):433-4

Number of dopamine neurons predicts prolactin levels in two inbred mouse strains. Sved AF, et al. **Experientia** 1985 May 15;41(5):644-6

Modulation of striatal enkephalinergic neurons by antipsychotic drugs. Hong JS, et al. **Fed Proc** 1985 Jun;44(9):2535-9

Pergolide mesylate inhibits exercise-induced prolactin release in man. De Meirleir K, et al. **Fertil Steril** 1985 Apr;43(4):628-31

Comparative studies of cardiovascular effects of a new dopamine agonist (SK&F 38393A) and dopamine. Tsai CS, et al. **Gen Pharmacol** 1985; 16(2):85-9

Plasma catecholamine and blood lactate cumulation during incremental exhaustive exercise. Lehmann M, et al. **Int J Sports Med** 1985 Apr; 6(2):78-81

Dopamine stimulated increase of GTP levels in the rat retina. Schaeffer JM, et al. **J Biol Chem** 1985 Apr 25;260(8):4555-7

Analysis of the positive inotropic effect of ibopamine in the blood-perfused canine papillary muscle. Kawahara K, et al. **J Cardiovasc Pharmacol** 1985 Mar-Apr;7(2):316-20

BIBLIOGRAPHY

Levels of dopamine and thyrotrophin-releasing hormone in hypophysial stalk blood during an oestrogen-stimulated surge of prolactin in the ovariectomized rat. de Greef WJ, et al. **J Endocrinol** 1985 Apr; 105(1):107-12

Synthesis and central dopaminergic effects of N-(4,6-dimethyl-2-pyridinyl)benzamides. Bouhayat S, et al. **J Med Chem** 1985 May;28(5):555-9

Dopamine sulfoconjugation in the rat brain: regulation by monoamine oxidase. Buu NT. **J Neurochem** 1985 Aug;45(2):470-6

3,4-Dihydroxyphenylethylamine and 5-hydroxytryptamine metabolism in the rat: acidic metabolites in cisternal cerebrospinal fluid before and after giving probenecid. Curzon G, et al. **J Neurochem** 1985 Aug; 45(2):508-13

Neurochemical profile of Lu 19-005, a potent inhibitor of uptake of dopamine, noradrenaline, and serotonin. Hyttel J, et al. **J Neurochem** 1985 May;44(5):1615-22

Evidence that [3H]dopamine is taken up and released from nondopaminergic nerve terminals in the rat substantia nigra in vitro. Kelly E, et al. **J Neurochem** 1985 Jul;45(1):137-44

Dopamine uptake is differentially regulated in rat striatum and nucleus accumbens. Missale C, et al. **J Neurochem** 1985 Jul;45(1):51-6

Preparation and characterization of antisera and monoclonal antibodies to serotonergic and dopaminergic ligands. Flurkey K, et al. **J Neuroimmunol** 1985 May;8(2-3):115-27

Pergolide elevation of MHPG sulphate concentration in rat hypothalamus blocked by spiperone and mimicked by other dopamine agonists. Fuller RW, et al. **J Pharm Pharmacol** 1985 Apr;37(4):268-70

Acute and subchronic effects of MJ-13859, a potential antipsychotic drug, on rat brain dopaminergic function. McMillen BA. **J Pharmacol Exp Ther** 1985 May;233(2):369-75

Role of dopamine in the neurotoxic effects of methamphetamine. Schmidt CJ, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):539-44

Further studies of dopamine metabolism and function in Tetrahymena. Gundersen RE, et al. **J Protozool** 1985 Feb;32(1):25-3

Benztropine inhibits toxicity of MPTP in mice [letter] Bradbury AJ, et al. **Lancet** 1985 Jun 22;1(8443):1444-5

Dopamine inhibition of anterior pituitary adenylate cyclase is mediated through the high-affinity state of the D2 receptor. Borgundvaag B, et al. **Life Sci** 1985 Jul 29;37(4):379-86

In vivo electrochemical studies of rat striatal dopamine and serotonin release after morphine. Broderick PA. **Life Sci** 1985 Jun 17; 36(24):2269-75

Firing properties of substantia nigra dopaminergic neurons in freely moving rats. Freeman AS, et al. **Life Sci** 1985 May 20; 36(20):1983-94

D2-dopamine receptor-mediated inhibition of cyclic AMP formation in striatal neurons in primary culture. Weiss S, et al. **Mol Pharmacol** 1985 Jun;27(6):595-9

Pharmacology in vivo of the phenylindan derivative, Lu 19-005, a new potent inhibitor of dopamine, noradrenaline and 5-hydroxytryptamine uptake in rat brain. Arnt J, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):101-7

Effects of discriminant and non-discriminant dopamine antagonists on in vivo accumulation of 3H-N-propyl-norapomorphine in mouse striatum and tuberculum olfactorium. Gulat-Marnay C, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):117-22

Amphetamine induced release of endogenous dopamine in vitro is not reduced following pretreatment with reserpine. Niddam R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):123-7

Chlorimipramine, electroconvulsive shock and combination thereof: differential effects of chronic treatment on apomorphine-induced behaviours and on striatal and mesocortical dopamine turnover. Spyraki C, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):128-34

Unexpected potentiation by discriminant benzamide derivatives of stereotyped behaviours elicited by dopamine agonists in mice. Vasse M, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):108-16

Comparison of release of endogenous dopamine and gamma-aminobutyric acid from rat caudate synaptosomes. Caudill WL, et al. **Neurochem Res** 1985 Mar;10(3):319-31

Release of endogenous dopamine, 3,4-dihydroxyphenylacetic acid, and amino acid transmitters from rat striatal slices. Flint RS, et al. **Neurochem Res** 1985 Apr;10(4):515-27

The uptake of serotonin and dopamine by homogenates of frozen rat and human brain tissue. Stenström A, et al. **Neurochem Res** 1985 May; 10(5):591-9

Electroacupuncture alters catecholamines in brain regions of rats. Sun AY, et al. **Neurochem Res** 1985 Feb;10(2):251-8

Hypoprolactinemia induced by hypophysectomy and long-term bromocriptine treatment decreases tuberoinfundibular dopaminergic neuronal activity and the responsiveness of these neurons to prolactin. Demarest KT, et al. **Neuroendocrinology** 1985 May;40(5):369-76

Dopamine-induced physical barrier to inhibit prolactin release in mammotrophs disappears during resumption of prolactin secretion. Reifel CW, et al. **Neuroendocrinology** 1985 May;40(5):438-43

Altered pharmacokinetics of L-dopa metabolism [letter] Melamed E, et al. **Neurology** 1985 Jun;35(6):939-41

Activation of muscarinic receptors on striatal synaptosomes increases the release of endogenous dopamine. Bonanno G, et al. **Neuropharmacology** 1985 Mar;24(3):261-4

The continuity of dopamine receptor antagonism can dictate the long-term behavioural consequences of a mesolimbic infusion of dopamine. Costall B, et al. **Neuropharmacology** 1985 Mar;24(3):193-7

Alterations in dopamine metabolism after chronic administration of haloperidol. Possible role of increased autoreceptor sensitivity. Saller CF, et al. **Neuropharmacology** 1985 Feb;24(2):123-9

The role of noradrenaline in tuning and dopamine in switching between signals in the CNS. Oades RD. **Neurosci Biobehav Rev** 1985 Summer; 9(2):261-82

Dopamine hyperpolarizes and reduces the light responses of rod ON-centre bipolar cells in the retina of the dogfish, Scyliorhinus canicula. Shiells RA, et al. **Neurosci Lett** 1985 Apr 19;55(3):331-6

Alteration of dopamine metabolism in different brain regions of the rabbit by estradiol and tamoxifen. Baksi SN, et al. **Neuroscience** 1985 Apr; 14(4):1053-9

Regulation of dopamine release by impulse flow and by autoreceptors as studied by in vivo voltammetry in the rat striatum. Gonon FG, et al. **Neuroscience** 1985 Mar;14(3):765-74

Effect of haloperidol and sulpiride on dopamine metabolism in nucleus accumbens and olfactory tubercle: a study by in vivo voltammetry. Louilot A, et al. **Neuroscience** 1985 Mar;14(3):775-82

Detection of homovanillic acid in vivo using microcomputer-controlled voltammetry: simultaneous monitoring of rat motor activity and striatal dopamine release. O'Neill RD, et al. **Neuroscience** 1985 Mar; 14(3):753-63

Morphological evidence for a dopaminergic terminal field in the hippocampal formation of young and adult rat. Verney C, et al. **Neuroscience** 1985 Apr;14(4):1039-52

Locomotor response of nialamide pretreated old rats to intraaccumbens dopamine. Cousin KM, et al. **Pharmacol Biochem Behav** 1985 Mar; 22(3):461-8

Effects of phencyclidine (PCP)-like drugs on turning behavior, 3H-dopamine uptake, and 3H-PCP binding. Johnson KM, et al. **Pharmacol Biochem Behav** 1985 May;22(5):731-5

Suppression of male copulatory behavior by delta 9-THC is not dependent on changes in plasma testosterone or hypothalamic dopamine or serotonin content. Shrenker P, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):415-20

Effects of ovariectomy and estrogen replacement on intrastriatal dopamine-elicited postural deviation. Smith RL, et al. **Pharmacol Biochem Behav** 1985 May;22(5):689-93

Dopamine decreases conductance of the electrical junctions between cultured retinal horizontal cells. Lasater EM, et al. **Proc Natl Acad Sci USA** 1985 May;82(9):3025-9

Central inhibitory action of TRH on prolactin secretion in the rat. Ohta H, et al. **Proc Soc Exp Biol Med** 1985 May;179(1):9-12

Neurotropic drugs and brain development: effects on cell replication in vivo and in vitro. Patel AJ. **Prog Clin Biol Res** 1985;163C:301-5

Chronic neuroleptic treatment and mesolimbic dopamine denervation induce behavioural supersensitivity to opiates. Stinus L, et al. **Psychopharmacology (Berlin)** 1985;85(3):323-8

Induction and reversal of dopamine dyskinesia in rat, cat, and monkey. Lloyd KG, et al. **Psychopharmacology [Suppl]** 1985;2:200-10

Studies on the stability of 3H-dopamine, 3H-apomorphine and 3H-ADTN: effects of sodium ascorbate and EDTA. Cabbat FS, et al. **Res Commun Chem Pathol Pharmacol** 1985 Mar;47(3):333-43

Effects of amfonelic acid, alpha-methyltyrosine, Ro 4-1284 and haloperidol pretreatment on the depletion of striatal dopamine by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine in mice. Fuller RW, et al. **Res Commun Chem Pathol Pharmacol** 1985 Apr;48(1):17-25

Effect of dopamine and dopamine-receptor blockade on in vitro renin release, tissue renin content and tissue cyclic AMP content in the rat. López GA, et al. **Rev Esp Fisiol** 1985 Mar;41(1):95-100

Inhibitory effects of dopamine and isoprenaline on antral motor activity stimulated by acetylcholine or physostigmine in vitro. Ulvestad A, et al. **Scand J Gastroenterol** 1985 Mar;20(2):243-6

Regional brain dopamine metabolism: a marker for the speed, direction, and posture of moving animals. Freed CR, et al. **Science** 1985 Jul 5; 229(4708):62-5

[Normal values of dopamine, noradrenaline, adrenaline, and 5 hydroxyindoleacetic acid in pregnancies of different gestational ages] Lerdo de Tejada A, et al. **Ginecol Obstet Mex** 1985 Feb; 53(334):49-52 (Eng. Abstr.) **(Spa)**

DOPAMINE BETA-HYDROXYLASE

A monoclonal antibody to dopamine beta-monooxygenase: detection of biosynthetic intermediates. Nolan J, et al. **Arch Biochem Biophys** 1985 Jul;240(1):257-64

3-Phenylpropenes as mechanism-based inhibitors of dopamine beta-hydroxylase: evidence for a radical mechanism. Fitzpatrick PF, et al. **Biochemistry** 1985 Apr 23;24(9):2108-14

Secondary isotope effects and structure-reactivity correlations in the dopamine beta-monooxygenase reaction: evidence for a chemical mechanism. Miller SM, et al. **Biochemistry** 1985 Apr 23; 24(9):2114-27

Immunohistochemical evidence for phenylethanolamine-N-methyltransferase-positive/tyrosine hydroxylase-negative neurones in the retina and the posterior hypothalamus of the rat. Foster GA, et al. **Brain Res** 1985 Mar 18; 330(1):183-8

The distribution of monoaminergic cells and fibers in a periventricular preoptic nucleus involved in the control of gonadotropin release: immunohistochemical evidence for a dopaminergic sexual dimorphism. Simerly RB, et al. **Brain Res** 1985 Mar 18;330(1):55-64

Study on the mechanism of the appearance of noise effects. Okada A, et al. **Eur J Applied Physiol** 1985;53(4):364-7

Sympathetic activity, plasma renin activity (PRA) and kininogen levels in patients haemodialysed with acetate and bicarbonate. Ksiażek A, et al. **Int Urol Nephrol** 1984;16(4):337-44

Dopamine beta-hydroxylase-like immunoreactivity in the rat and cat carotid body: a light and electron microscopic study. Chen IL, et al. **J Neurocytol** 1985 Feb;14(1):131-44

Changes in dopamine-beta-hydroxylase, and copper, and catecholamine concentrations in human plasma with physical exercise. Ohno H, et al. **J Sports Med Phys Fitness** 1984 Dec;24(4):315-20

Dopamine-beta-hydroxylase inhibitors, feeding and locomotor activity: reinstatement of feeding following central norepinephrine. Evans KR, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):535-40

DOXAPRAM

Antagonism of xylazine sedation with yohimbine, 4-aminopyridine, and doxapram in dogs. Hatch RC, et al. **Am J Vet Res** 1985 Feb; 46(2):371-5

Effects of doxapram on body temperature of the rat during radiofrequency irradiation. Jauchem JR, et al. **Clin Exp Pharmacol Physiol** 1985 Jan-Feb;12(1):1-8

DOXEPIN

Effect of single and repeated doses of activated charcoal on the pharmacokinetics of doxepin. Scheinin M, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Jan;23(1):38-42

ELECTROCONVULSIVE THERAPY

Plasma catecholamines and ECT. Khan A, et al. **Biol Psychiatry** 1985 Jul;20(7):799-804

Electroconvulsive therapy and schizophrenia. Van Valkenburg C, et al. **Biol Psychiatry** 1985 Jul;20(7):699-700

[Effect of electroconvulsive shock on brain monoamines] Kuang PG. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1985 Feb; 18(1):41-4 (Eng. Abstr.) **(Chi)**

ELECTROENCEPHALOGRAPHY

Effects of fentanyl citrate and droperidol on electroencephalographic findings in dogs. Katherman AE, et al. **Am J Vet Res** 1985 Apr; 46(4):974-6

The effects of aniracetam on primate behavior and EEG. Schwam E, et al. **Ann NY Acad Sci** 1985;444:482-4

Hippocampal-dentate theta disturbance after selective CA1 pyramidal cell damage in the rat. Monmaur P, et al. **Brain Res** 1985 Mar 4; 328(2):301-11

Cocaine increases EEG beta: a replication and extension of Hans Berger's historic experiments. Herning RI, et al. **Electroencephalogr Clin Neurophysiol** 1985 Jun;60(6):470-7

Characteristics of the cortical and hippocampal EEG power spectra of rabbits during normal behavioral states and after administration of CNS acting drugs. Yamamoto J. **Jpn J Pharmacol** 1985 Mar;37(3):227-34

Quantitative electrocortical changes in the rat induced by phencyclidine and other stimulants. Neal H, et al. **Neuropharmacology** 1985 Apr; 24(4):317-23

ELECTROLYTES

Steroids alter ion transport and absorptive capacity in proximal and distal colon. Sellin JH, et al. **Am J Physiol** 1985 Jul;249(1 Pt 1):G113-9

The pharmacological modification of secretory responses. Miller RJ, et al. **Ciba Found Symp** 1985;112:155-74

Effects of chronic changes in dietary electrolytes and acute stress on plasma levels of corticosterone and aldosterone in the duck (Anas platyrhynchos). Klingbeil CK. **Gen Comp Endocrinol** 1985 Apr; 58(1):10-9

Electrolyte transport across the basolateral membrane of the parietal cells. Muallem S, et al. **J Biol Chem** 1985 Jun 10;260(11):6641-53

ELECTROSHOCK

Differential effects of electroconvulsive shock on four models of experimentally-induced aggression in rats. Liou SY, et al. **Jpn J Pharmacol** 1985 Feb;37(2):167-72

Chlorimipramine, electroconvulsive shock and combination thereof: differential effects of chronic treatment on apomorphine-induced behaviours and on striatal and mesocortical dopamine turnover. Spyraki C, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):128-34

Down-regulation of beta-adrenoceptors in rat cortex by repeated administration of desipramine, electroconvulsive shock and clenbuterol requires 5-HT neurones but not 5-HT. Nimgaonkar VL, et al. **Neuropharmacology** 1985 Apr;24(4):279-83

Increased sensitivity to serotonergic agonists after repeated electroconvulsive shock in rats. Wielosz M. **Pharmacol Biochem Behav** 1985 May;22(5):683-7

EMOTIONS

Elevation of mood due to antidepressants [letter] Pearce PL. **JAMA** 1985 Jun 7;253(21):3091-2

A preliminary report on anti-depressant therapy and its effects on hope and immunity. Udelman DL, et al. **Soc Sci Med** 1985; 20(10):1069-72

ENDORPHINS

Maternal and fetal beta-endorphin release in response to the stress of labor and delivery. Kofinas GD, et al. **Am J Obstet Gynecol** 1985 May 1;152(1):56-9

Endogenous opioid immunoreactivity in rat spinal cord following traumatic injury. Faden AI, et al. **Ann Neurol** 1985 Apr; 17(4):386-90

Response of the rat brain beta-endorphin system to novelty: importance of the fornix connection. Netto CA, et al. **Behav Neural Biol** 1985 Jan; 43(1):37-46

Modification of opioid ligand binding in the central and the peripheral nervous system by different buffers. Bourhim N, et al. **Biochem Biophys Res Commun** 1985 Jun 14;129(2):328-33

Ginseng saponin treatment does not alter brain or pituitary levels of beta-endorphin and dynorphin. Ho WK, et al. **Biochem Pharmacol** 1985 Jun 1;34(11):2044-6

Nitrous oxide inhalation does not influence plasma concentrations of beta-endorphin or Met-enkephalin-like immunoreactivity. Evans SF, et al. **Br J Anaesth** 1985 Jun;57(6):624-8

Altered body temperature of rabbits after central injection of beta-endorphin and other peptides. Glyn-Ballinger JR, et al. **Brain Res** 1985 May 6;333(2):366-8

Distribution of the pro-opiomelanocortin derived peptides, adrenocorticotrope hormone, alpha-melanocyte-stimulating hormone and beta-endorphin (ACTH, alpha-MSH, beta-END) in the rat hypothalamus. Mezey E, et al. **Brain Res** 1985 Mar 4;328(2):341-7

Immunohistochemical localization of neurotensin and beta-endorphin in the rat anterior pituitary gland. Miyoshi R, et al. **Brain Res** 1985 Apr 8;331(2):386-8

Possible interactions between dynorphin and dopaminergic systems in rat basal ganglia and substantia nigra. Quirion R, et al. **Brain Res** 1985 Apr 8;331(2):358-62

Modulation of lordosis behaviour in the female rat by corticotropin releasing factor, beta-endorphin and gonadotropin releasing hormone in the mesencephalic central gray. Sirinathsinghji DJ. **Brain Res** 1985 Jun 10;336(1):45-55

Ultrastructural evidence for beta-endorphin-like immunoreactivity in the nervous system of the rat duodenum. Wolter HJ. **Brain Res** 1985 May 13;334(1):194-9

Homeostatic alterations with major trauma. Arachidonic acid metabolites and endorphins. DeMajo WA. **Can Anaesth Soc J** 1985 May; 32(3 Pt 1):241-2

Occurrence of beta-endorphin-like immunoreactive cells in the neural complex of a protochordate. Pestarino M. **Cell Mol Biol** 1985; 31(1):27-31

Determination of beta-endorphin and beta-lipotropin in human cerebrospinal fluid. Laatikainen TJ, et al. **Clin Chim Acta** 1985 Feb 15;145(3):325-9

Endogenous opioids in marine invertebrates. Piccoli R, et al. **Comp Biochem Physiol** [C] 1985;80(2):237-40

Ovarian immunoreactive beta-endorphin and estrous cycle in the rat. Lolait SJ, et al. **Endocrinology** 1985 Jul;117(1):161-8

Changes in beta-endorphin-like immunoreactivity in pituitary portal blood during the estrous cycle and after ovariectomy in rats. Sarkar DK, et al. **Endocrinology** 1985 May;116(5):2075-9

Corticotropin-releasing factor stimulation of adrenocorticotropin and beta-endorphin release: effects of acute and chronic stress. Young EA, et al. **Endocrinology** 1985 Jul;117(1):23-30

Plasma immunoreactive beta-endorphin and cortisol in the newborn infant after elective caesarean section and after spontaneous labour. Pohjavuori M, et al. **Eur J Obstet Gynecol Reprod Biol** 1985 Feb;19(2):67-74

Isolation and characterization of dipeptidyl peptidase IV from human meconium. Functional role of beta-casomorphins. Caporale C, et al. **FEBS Lett** 1985 May 20;184(2):273-7

The identification and characterization of alpha-N-acetylated beta-endorphin in the human pituitary gland. Smith AI, et al. **FEBS Lett** 1985 Jun 3;185(1):109-11

Endogenous opioid nomenclature: light at the end of the tunnel. Kitchen I. **Gen Pharmacol** 1985;16(2):79-84 (48 ref.)

Beta-endorphin and cold pressor test in the aged. Casale G, et al. **Gerontology** 1985;31(2):101-5

Temporal difference of thyrotropin-releasing hormone in prevention of testicular regression in golden hamsters exposed to short photoperiods: possible involvement of beta-endorphin. Chen HJ, et al. **Horm Res** 1985; 21(3):168-74

Bacterial lipopolysaccharide induction of leukocyte-derived corticotropin and endorphins. Harbour-McMenamin D, et al. **Infect Immun** 1985 Jun; 48(3):813-7

Preparation and properties of tritiated human [Tyr18, Trp27]-beta-endorphin. Hammonds RG Jr, et al. **Int J Pept Protein Res** 1985 Feb;25(2):149-54

Identification of N alpha-acetyl-alpha-endorphin and N alpha-acetyl-gamma-endorphin isolated from the neurointermediate lobe of the rat pituitary gland. Burbach JP, et al. **J Biol Chem** 1985 Jun 10;260(11):6663-9

beta-Casomorphin immunoreactive materials in cows' milk incubated with various bacterial species. Hamel U, et al. **J Dairy Res** 1985 Feb; 52(1):139-48

Opioid peptides of the pituitary and hypothalamus: changes in pregnant and lactating rats. Petraglia F, et al. **J Endocrinol** 1985 May; 105(2):239-45

Plasma beta-endorphin levels after exercise [letter] De Meirleir, et al. **J Endocrinol Invest** 1985 Feb;8(1):89

Preembedding colloidal gold immunostaining of hypothalamic neurons: light and electron microscopic localization of beta-endorphin-immunoreactive perikarya. Lamberts R, et al. **J Histochem Cytochem** 1985 Jun;33(6):499-507

Beta-endorphin-(10-16) antagonizes behavioral responses elicited by melatonin following injection into the nucleus accumbens of rats. Gaffori O, et al. **Life Sci** 1985 Jul 29;37(4):357-64

N alpha-Acetyl-gamma-endorphin is an endogenous non-opioid neuropeptide with biological activity. Wiegant VM, et al. **Life Sci** 1985 Jun 17;36(24):2277-85

Auto-tolerance to the endogenous opioids and sleep. Gillman MA, et al. **Med Hypotheses** 1985 Apr;16(4):393-5

The use of reverse-phase chromatographic procedures coupled with radioimmunoassay in studying regional distribution of beta h-endorphin in the human brain. Pasi A, et al. **Neurobehav Toxicol Teratol** 1985 Mar-Apr;7(2):199-201

Senescent change in tissue weight and immunoreactive beta-endorphin, enkephalin, and vasopressin in eight regions of C57BL/6J mouse brain and pituitary. Rogers J, et al. **Neurobiol Aging** 1985 Spring;6(1):1-9

Postnatal development of beta-endorphin immunoreactivity in the medulla oblongata of rat. Alessi NE, et al. **Neuropeptides** 1985 Feb; 5(4-6):473-6

Separate populations of opioid containing neurons in the guinea-pig intestine. Costa M, et al. **Neuropeptides** 1985 Feb;5(4-6):445-8

Action of neutral metalloendopeptidase ('enkephalinase') on beta-endorphin. Gráf L, et al. **Neuropeptides** 1985 Mar;6(1):13-9

Beta-endorphin processing in pituitary and brain is sensitive to haloperidol stimulation. Ham J, et al. **Neuropeptides** 1985 Feb;5(4-6):497-500

Postnatal development of opioid systems in rat brain. Loughlin SE, et al. **Neuropeptides** 1985 Feb;5(4-6):469-72

Differential modulation of the beta-endorphin and dynorphin systems by serotonergic stimulation in the rat. Majeed NH, et al. **Neuropeptides** 1985 Feb;5(4-6):563-6

A comparison of opioid peptide precursors in guinea pig, rat and bovine striata and guinea pig adrenal. Metters KM, et al. **Neuropeptides** 1985 Feb;5(4-6):521-4

The effect of morphine upon CSF opioids in dogs. Noel MA, et al. **Neuropeptides** 1985 Feb;5(4-6):429-32

Antidepressants and endogenous opioid peptide systems. Przewlocki R, et al. **Neuropeptides** 1985 Feb;5(4-6):575-8

Dermorphin-like immunoreactivity in guinea pig and rat stomach. Tsou K, et al. **Neuropeptides** 1985 Feb;5(4-6):449-52

How is kyotorphin (Tyr-Arg) generated in the brain? Ueda H, et al. **Neuropeptides** 1985 Feb;5(4-6):525-8

Enkephalins and endorphins: activation molecules for the immune system and natural killer activity? Wybran J. **Neuropeptides** 1985 Feb; 5(4-6):371-4

Changes in releasability of ACTH and beta-endorphin with chronic stress. Young E, et al. **Neuropeptides** 1985 Feb;5(4-6):545-8

The effect of surgery on plasma beta-endorphin and methionine-enkephalin. Smith R, et al. **Neurosci Lett** 1985 Mar 22; 55(1):17-21

Acupuncture analgesia [letter] Han JS. **Pain** 1985 Mar;21(3):307-10

Effects of intracranial self-stimulation on brain opioid peptides. Stein EA. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):67-73

Binding characteristics of dermorphin, and [dermorphin1-7]-beta c-endorphin in rat brain membranes. Westphal M, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):149-52

Stress produces opioid-like effects on investigatory behavior. Arnsten AF, et al. **Pharmacol Biochem Behav** 1985 May;22(5):803-9

Opiomelanocortins and behavioral adaptation. Bohus B. **Pharmacol Ther** 1984;26(3):417-51 (238 ref.)

The effect of chronic estrogen treatment on immunoreactive beta-endorphin levels in intact female rats. Forman LJ, et al. **Proc Soc Exp Biol Med** 1985 Jul;179(3):365-72

Glucocorticoid inhibition of immunoreactive beta-endorphin release from the anterior lobe of the rat pituitary: in vitro and in vivo studies. Mueller GP, et al. **Proc Soc Exp Biol Med** 1985 Jul;179(3):338-47

Endogenous opioid activity in clinical hemorrhagic shock. Shatney CH, et al. **Surg Gynecol Obstet** 1985 Jun;160(6):547-51

[Endogenous opioids] Schulz R, et al. **Tierarztl Prax** 1985;13(1):11-27 (93 ref.) (Eng. Abstr.) **(Ger)**

[Endorphins and pregnancy] Stoppelli I, et al. **Minerva Ginecol** 1984 Dec; 36(12):761-6 (Eng. Abstr.) **(Ita)**

[Effects of diltiazem on plasma ACTH, beta-ELI and ADH levels during surgery] Kono K, et al. **Masui** 1985 Jan;34(1):18-24 (Eng. Abstr.) **(Jpn)**

[Neuro-intestinal peptides and peptide-producing cells--immunohistocytochemistry of catecholamines and opioid peptides in the hamster adrenal medulla] Kobayashi S, et al. **Nippon Heikatsukin Gakkai Zasshi** 1984 Oct;20(5):393-9 **(Jpn)**

[Brain blood supply and beta-endorphin and corticotropin content on exposure to thyroliberin] Mirozoian RS, et al. **Biull Eksp Biol Med** 1985 Mar;99(3):318-20 (Eng. Abstr.) **(Rus)**

[Changes in the opioid peptide content of the adrenals of rats during immobilization stress] Val'dman AV, et al. **Biull Eksp Biol Med** 1985 Apr;99(4):404-6 (Eng. Abstr.) **(Rus)**

[Immunoreactive beta-lipotropin and endorphins are secreted by the isolated alimentary complex of rats] Titov MI, et al. **Dokl Akad Nauk SSSR** 1985;281(2):497-9 **(Rus)**

ENKEPHALIN, LEUCINE

The stimulation of glycogenolysis in isolated hepatocytes by opioid peptides. Leach RP, et al. **Biochem J** 1985 Apr 1;227(1):191-7

The metabolism of neuropeptides. Endopeptidase-24.11 in human synaptic membrane preparations hydrolyses substance P. Matsas R, et al. **Biochem J** 1985 Jun 1;228(2):487-92

Central versus peripheral actions of Leu-enkephalin on acquisition of a one-way active avoidance response in rats. Martinez JL Jr, et al. **Brain Res** 1985 Feb 18;327(1-2):37-43

Blockade of cholinergic receptors in the C1 area abolishes hypertensive response to opiates in the A1 area of the ventrolateral medulla. Punnen S, et al. **Brain Res** 1985 Jun 10;336(1):180-6

Possible interactions between dynorphin and dopaminergic systems in rat basal ganglia and substantia nigra. Quirion R, et al. **Brain Res** 1985 Apr 8;331(2):358-62

Blood-brain barrier permeability to leucine-enkephalin, D-alanine2-D-leucine5-enkephalin and their N-terminal amino acid (tyrosine). Zlokovic BV, et al. **Brain Res** 1985 Jun 10;336(1):125-32

Effect of hemorrhage on vasopressin, dynorphin A, and leu5-enkephalin in the hypothalamo-pituitary system of the rat. Feuerstein G, et al. **Clin Exp Hypertens** [A] 1984;6(10-11):1973-6

Influence of intracerebroventricular (ICV) GTP-electrolyte infusion on ICV (D-ALA2, D-LEU5) enkephalin (DADL)-induced cardiovascular effects in rats. McDonald WJ, et al. **Clin Exp Hypertens** [A] 1984;

6(10-11):1837-41

Effects of traumatic injury on dynorphin immunoreactivity in spinal cord. Cox BM, et al. **Neuropeptides** 1985 Feb;5(4-6):571-4

Studies in vitro with ICI 174,864, [D-Pen2, D-Pen5]-enkephalin (DPDPE) and [D-Ala2, NMePhe4, Gly-ol]-enkephalin (DAGO). Hirning LD, et al. **Neuropeptides** 1985 Feb;5(4-6):383-6

Localization and quantitation of proenkephalin-derived neuropeptides in the rat hippocampus. Hoffman DW, et al. **Neuropeptides** 1985 Feb; 5(4-6):437-40

Development of hypothalamic opioid neurons: a combined immunocytochemical and [3H]thymidine autoradiographic study. Khachaturian H, et al. **Neuropeptides** 1985 Feb;5(4-6):477-80

Opiate receptor-mediated chemotaxis of human monocytes. Ruff MR, et al. **Neuropeptides** 1985 Feb;5(4-6):363-6

Characterization of a high molecular weight polypeptide from spinal cord with (Leu) enkephalin-immunoreactivity. Wahlström A, et al. **Neuropeptides** 1985 Feb;5(4-6):509-12

Dynorphinergic pathways of Leu-enkephalin production in the rat brain. Zamir N, et al. **Neuropeptides** 1985 Feb;5(4-6):441-4

A study of intracerebroventricular self-administration of leucine or methionine enkephalin by rats in response to intermittent electric shocks. Dib B. **Pain** 1985 May;22(1):49-57

A general procedure for analysis of proenkephalin B derived opioid peptides. Christensson-Nylander I, et al. **Regul Pept** 1985 May; 11(1):65-76

[The nature of cation-binding groups in binding sites for [[3H]Tyr1, D-Ala2, D-Leu5]enkephalin] Zaitsev SV, et al. **Bioorg Khim** 1985 Feb; 11(2):153-61 (Eng. Abstr.) **(Rus)**

ENKEPHALIN, METHIONINE

Protected homocysteine peptides as precursors of labelled methionine peptides. Application in preparation of methionine-enkephalin. Någren K, et al. **Acta Chem Scand [B]** 1985;39(3):157-61

Enzyme-linked immunosorbent assay for Met-enkephalin using unconjugated enkephalin as a solid phase antigen. Takesue Y, et al. **Anal Biochem** 1985 Apr;146(1):35-9

The stimulation of glycogenolysis in isolated hepatocytes by opioid peptides. Leach RP, et al. **Biochem J** 1985 Apr 1;227(1):191-7

Nitrous oxide inhalation does not influence plasma concentrations of beta-endorphin or Met-enkephalin-like immunoreactivity. Evans SF, et al. **Br J Anaesth** 1985 Jun;57(6):624-8

Met-enkephalin-Arg6-Gly7-Leu8 in the organ of Corti: high performance liquid chromatography and immunoelectron microscopy. Eybalin M, et al. **Brain Res** 1985 Apr 8;331(2):389-95

Dopamine receptors regulate Met-enkephalin content in pituitary. George SR, et al. **Brain Res** 1985 May 13;334(1):187-9

Development of methionine-enkephalin in microdissected areas of the rabbit brain. Gingras-Leatherman JL, et al. **Brain Res** 1985 Jun 10; 336(1):73-80

The opioid octapeptide Met5-enkephalin-Arg6-Gly7-Leu8: characterization and distribution in rat spinal cord. Iadarola MJ, et al. **Brain Res** 1985 Mar 18;330(1):127-34

Evidence for the coexistence of acetylcholine and enkephalin in the sympathetic preganglionic neurons of rats. Kondo H, et al. **Brain Res** 1985 Jun 3;335(2):309-14

Possible interactions between dynorphin and dopaminergic systems in rat basal ganglia and substantia nigra. Quirion R, et al. **Brain Res** 1985 Apr 8;331(2):358-62

Effects of enkephalin and 5-hydroxytryptamine on solitary tract neurones involved in respiration and respiratory reflexes. Sessle BJ, et al. **Brain Res** 1985 Feb 18;327(1-2):221-30

Occurrence of met-enkephalin, met-enkephalin-Arg6-Phe7 and met-enkephalin-Arg6-Gly7-Leu8 in gastrin cells of hog antral mucosa. Jönsson AC. **Cell Tissue Res** 1985;240(2):361-5

Potential role of met-enkephalin in short term regulation of blood pressure in anesthetized rabbits. Rhee HM, et al. **Clin Exp Hypertens [A]** 1984; 6(10-11):2063-7

Methionine enkephalin as a possible neuromodulator of regional cerebral blood flow. Blum K, et al. **Experientia** 1985 Jul 15;41(7):932-3

Modulation of striatal enkephalinergic neurons by antipsychotic drugs. Hong JS, et al. **Fed Proc** 1985 Jun;44(9):2535-9

Evaluation of BW942C, a novel antidiarrheal agent, against enterotoxins of Escherichia coli and Vibrio cholerae. Morgan DR, et al. **Infect Immun** 1985 Jun;48(3):754-8

Methionine-enkephalin inhibits stress-induced increases in noradrenaline turnover in brain regions of rats. Tanaka M, et al. **Jpn J Pharmacol** 1985 Jan;37(1):117-9

Characterization of rat brain opioid receptors by [Tyr-3,5-3H]1, D-Ala2, Leu5-enkephalin binding. Benyhe S, et al. **Neurochem Res** 1985 May; 10(5):627-35

Localization and quantitation of proenkephalin-derived neuropeptides in the rat hippocampus. Hoffman DW, et al. **Neuropeptides** 1985 Feb; 5(4-6):437-40

Release of high molecular weight forms of met5-enkephalin-arg6-gly7-leu8 from rat brain. Lindberg I, et al. **Neuropeptides** 1985 Feb;5(4-6):541-4

Prodynorphin immunoreactivity is located in different neurons than proenkephalin immunoreactivity in the cerebral cortex of rats. McGinty JF. **Neuropeptides** 1985 Feb;5(4-6):465-8

Adrenorphin immunoreactivity in rat brain. Miyata A, et al. **Neuropeptides** 1985 Feb;5(4-6):517-20

Release of synenkephalin from neuronal terminals in vitro. Rossier J, et al. **Neuropeptides** 1985 Feb;5(4-6):549-52

Astrocyte opioid receptors: activation modifies the noradrenaline-evoked increase in 2-[14C]deoxyglucose incorporation into glycogen. Pearce B, et al. **Neurosci Lett** 1985 Apr 9;55(2):157-60

The effect of surgery on plasma beta-endorphin and methionine-enkephalin. Smith R, et al. **Neurosci Lett** 1985 Mar 22; 55(1):17-21

Effect of histamine infusion on circulating methionine-enkephalin and catecholamine concentrations. Smith R, et al. **Neurosci Lett** 1985 Apr 19;55(3):289-92

Mesencephalic pathway to the retina exhibits enkephalin-like immunoreactivity. Weiler R. **Neurosci Lett** 1985 Mar 22;55(1):11-6

A study of intracerebroventricular self-administration of leucine or methionine enkephalin by rats in response to intermittent electric shocks. Dib B. **Pain** 1985 May;22(1):49-57

Effects of MET-ENK, substance P and SRIF on the behavior of Hemichromis bimaculatus. Christ H. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):139-48

Cardiovascular interactions between methionine-enkephalin and substance P in the conscious dog. Sander GE, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):133-7

[Effect of an enkephalin analog on the endocrine system in man] Földes J, et al. **Orv Hetil** 1985 May 12;126(19):1145-8 (Eng. Abstr.) **(Hun)**

ENKEPHALINS

Enkephalin-degrading dipeptidyl carboxypeptidase in guinea pig serum: its properties and action on bioactive peptides. Kase R, et al. **Arch Biochem Biophys** 1985 Jul;240(1):330-6

Enkephalin neurons in the guinea pig proximal colon: an immunocytochemical study using an antiserum to methionine-enkephalin-Arg6-Gly7-Leu8. Kobayashi S, et al. **Arch Histol Jpn** 1985 Feb;48(1):27-44

Enkephalin metabolism and its inhibition. Gros C, et al. **Biochem Soc Trans** 1985 Feb;13(1):47-50

Identification of aminopeptidase M as an enkephalin-inactivating enzyme in rat cerebral membranes. Gros C, et al. **Biochemistry** 1985 Apr 23; 24(9):2179-85

Evidence for synenkephalin-like immunoreactivity in pontobulbar monoaminergic neurons of the cat. Charnay Y, et al. **Brain Res** 1985 May 27;335(1):160-4

Spinal parasympathetic enkephalin fibers: patterns and projections. Romagnano MA, et al. **Brain Res** 1985 May 27;335(1):174-81

An enkephalinergic projection from the hypothalamic paraventricular nucleus to the hypothalamic ventromedial nucleus of the rat: an experimental immunohistochemical study. Yamano M, et al. **Brain Res** 1985 Apr 1;331(1):25-33

Light- and electron-microscopic demonstration of enkephalin-like immunoreactivity in paraganglia of the human urinary bladder. Vaalasti A, et al. **Cell Tissue Res** 1985;239(3):683-7

Quantitation of proenkephalin A messenger RNA in bovine brain, pituitary and adrenal medulla: correlation between mRNA and peptide levels. Pittius CW, et al. **EMBO J** 1985 May;4(5):1257-60

Proenkephalin and prodynorphin related neuropeptides in the cochlea. Hoffman DW, et al. **Hear Res** 1985 Jan;17(1):47-50

Localization of enkephalins in adrenaline cells and the nerves innervating adrenaline cells in rat adrenal medulla. Pelto-Huikko M, et al. **Histochemistry** 1985;82(4):377-83

Selective regulation of carboxypeptidase peptide hormone-processing enzyme during enkephalin biosynthesis in cultured bovine adrenomedullary chromaffin cells. Hook VY, et al. **J Biol Chem** 1985 May 25;260(10):5991-7

Separation of enkephalins from their metabolites and precursor by a single pump gradient high-performance liquid chromatographic method. Hui KS, et al. **J Chromatogr** 1985 Jun 7;325(2):467-72

Immunological characterization of secretory proteins of chromaffin granules: chromogranins A, chromogranins B, and enkephalin-containing peptides. Fischer-Colbrie R, et al. **J Neurochem** 1985 Jun;44(6):1854-61

Characterization of membrane-bound aminopeptidases from rat brain: identification of the enkephalin-degrading aminopeptidase. Hersh LB. **J Neurochem** 1985 May;44(5):1427-35

Changes from enkephalin-like to gastrin/cholecystokinin-like immunoreactivity in snail neurons. Gesser BP, et al. **J Neurosci** 1985 Jun;5(6):1412-7

Nasal delivery of polypeptides I: nasal absorption of enkephalins in rats. Su KS, et al. **J Pharm Sci** 1985 Apr;74(4):394-8

Mu1: a very high affinity subtype of enkephalin binding sites in rat brain. Lutz RA, et al. **Life Sci** 1985 Jun 10;36(23):2233-8

Senescent change in tissue weight and immunoreactive beta-endorphin, enkephalin, and vasopressin in eight regions of C57BL/6J mouse brain and pituitary. Rogers J, et al. **Neurobiol Aging** 1985 Spring;6(1):1-9

Peripheral enkephalin hydrolysis in different animal species: a comparative study. Venturelli F, et al. **Neurochem Res** 1985 Mar;10(3):333-42

Substance P, enkephalins, somatostatin, cholecystokinin, oxytocin, and vasopressin in human spinal cord. Schoenen J, et al. **Neurology** 1985 Jun;35(6):881-90

Influence of acute, subchronic and chronic treatment with neuroleptic (haloperidol) on enkephalins and their precursors in the striatum of rat brain. Blanc D, et al. **Neuropeptides** 1985 Feb;5(4-6):567-70

Studies in vitro with ICI 174,864, [D-Pen2, D-Pen5]-enkephalin (DPDPE) and [D-Ala2, NMePhe4, Gly-ol]-enkephalin (DAGO). Hirning LD, et al. **Neuropeptides** 1985 Feb;5(4-6):383-6

Prodynorphin immunoreactivity is located in different neurons than proenkephalin immunoreactivity in the cerebral cortex of rats. McGinty JF. **Neuropeptides** 1985 Feb;5(4-6):465-8

Partial purification and characterisation of a 31 kDalton putative enkephalin precursor from guinea pig striatum. Metters KM, et al. **Neuropeptides** 1985 Feb;5(4-6):505-8

Identification of high molecular weight enkephalin percursor forms in human cerebrospinal fluid. Nyberg F, et al. **Neuropeptides** 1985 Feb; 5(4-6):537-40

Characterization of a new 23 kDalton enkephalin-containing protein in the bovine adrenal medulla. Patey G, et al. **Neuropeptides** 1985 Feb; 5(4-6):513-6

Release of synenkephalin from neuronal terminals in vitro. Rossier J, et al. **Neuropeptides** 1985 Feb;5(4-6):549-52

Leumorphin in human brain. Suda M, et al. **Neuropeptides** 1985 Feb; 5(4-6):461-4

The comparative distribution of enkephalin, dynorphin and substance P in the human globus pallidus and basal forebrain. Haber SN, et al. **Neuroscience** 1985 Apr;14(4):1011-24

Comparison of substance P and enkephalin distribution in rat brain: an overview using radioimmunocytochemistry. McLean S, et al. **Neuroscience** 1985 Mar;14(3):837-52

Sequence and expression of the rat prodynorphin gene. Civelli O, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(12):4291-5

A general procedure for analysis of proenkephalin B derived opioid peptides. Christensson-Nylander I, et al. **Regul Pept** 1985 May; 11(1):65-76

[Enkephalin-noradrenaline interactions in synaptic transmission] Fan JZ, et al. **Sheng Li Ko Hsueh Chin Chan** 1985 Apr;16(2):158-60 **(Chi)**

[Enkephalins and hormonal-metabolic reactions in experimental stress of differing severity] Lishmanov IuB, et al. **Biull Eksp Biol Med** 1985 Mar; 99(3):269-71 (Eng. Abstr.) **(Rus)**

ENURESIS

[Catecholaminergic activity in children with nocturnal enuresis] Szewczyk L. **Pediatr Pol** 1984 Oct;59(10):841-5 (Eng. Abstr.) **(Pol)**

EPHEDRINE

Bioavailability assessment of a new liquid controlled-release pseudoephedrine product. Graves DA, et al. **Clin Pharm** 1985 Mar-Apr; 4(2):199-203

Aperistalsis of the vas deferens corrected with administration of ephedrine. Tiffany P, et al. **J Urol** 1985 Jun;133(6):1060-1

EPINEPHRINE

Effect of propranolol on post-traumatic hypophosphataemia and catecholamine secretion. Lovén L, et al. **Acta Chir Scand** 1985; 151(3):201-4

Changes in blood level of catecholamines during arterial blood pressure rise induced with sciatic nerve stimulation. Całkosiński I, et al. **Acta Physiol Pol** 1984 Jan-Feb;35(1):47-51

Seasonal changes in blood lipids, adrenaline, noradrenaline, glucose and insulin in Norwegian reindeer. Larsen TS, et al. **Acta Physiol Scand** 1985 May;124(1):53-9

Human platelet alpha 2-adrenergic receptors: effect of Na+ on interaction with the adenylate cyclase system and on epinephrine-stimulated platelet secretion. Limbird LE, et al. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:235-42

Neural and transmitter influence on the capillary diameter in exteriorized frog mesentery. Dietrich HH, et al. **Adv Exp Med Biol** 1984; 180:701-9

Effect of a benzodiazepine (alprazolam) on plasma epinephrine and norepinephrine levels during exercise stress. Stratton JR, et al. **Am J Cardiol** 1985 Jul 1;56(1):136-9

Intravascular lidocaine toxicity: influence of epinephrine and route of administration. Yagiela JA. **Anesth Prog** 1985 Mar-Apr;32(2):57-61

Effect of amines on fibrinogen synthesis. Roy AK, et al. **Arch Biochem Biophys** 1985 Jun;239(2):364-7

Depletion of adrenal catecholamines alters the amnestic effect of amygdala stimulation. Bennett C, et al. **Behav Brain Res** 1985 Apr;15(2):83-91

Peripheral epinephrine modulates the effects of post-training amygdala stimulation on memory. Liang KC, et al. **Behav Brain Res** 1985 Apr; 15(2):93-100

Stimulation of inositol trisphosphate formation in hepatocytes by vasopressin, adrenaline and angiotensin II and its relationship to changes in cytosolic free Ca2+. Charest R, et al. **Biochem J** 1985 Apr 1; 227(1):79-90

Effects of phorbol esters on alpha 1-adrenergic-mediated and glucagon-mediated actions in isolated rat hepatocytes. García-Sáinz JA, et al. **Biochem J** 1985 May 15;228(1):277-80

Hepatic thiol and glutathione efflux under the influence of vasopressin, phenylephrine and adrenaline. Sies H, et al. **Biochem J** 1985 Mar 1; 226(2):545-9

Effect of methyl palmoxirate, an oral hypoglycemic agent, on epinephrine-induced hyperglycemia in the rat. Tutwiler GF, et al. **Biochem Pharmacol** 1985 Jun 15;34(12):2217-20

The effect of catecholamines and adenosine deaminase on the glucose transport system in rat adipocytes. Gliemann J, et al. **Biochim Biophys Acta** 1985 Jun 30;845(3):373-9

Factor analytic derivation of the MHPG/NM ratio: implications for studying the link between physical fitness and depression. Sothmann MS, et al. **Biol Psychiatry** 1985 May;20(5):579-83

Catecholamine responses to changes in posture during human pregnancy. Whittaker PG, et al. **Br J Obstet Gynaecol** 1985 Jun;92(6):586-92

Corticotropin-releasing factor: a physiologic regulator of adrenal epinephrine secretion. Brown MR, et al. **Brain Res** 1985 Mar 4; 328(2):355-7

Epinephrine- and norepinephrine-evoked potential changes of frog primary afferent terminals: pharmacological characterization of alpha and beta components. Wohlberg CJ, et al. **Brain Res** 1985 Feb 18; 327(1-2):289-301

Acetaminophen administration interferes with urinary metanephrine (and catecholamine) determinations [letter] Wilson SP, et al. **Clin Chem** 1985 Jun;31(6):1093-4

Blood pressure responses to ACTH and adrenaline infusions in dogs. Anderson WP, et al. **Clin Exp Hypertens** [A] 1985;7(4):525-37

Alpha 1-adrenergic responsiveness of young adult and aged rat submandibular cells in vitro. Baum BJ, et al. **Comp Biochem Physiol** [C] 1985;81(1):121-4

Accumulation of intra-arterially administered [3H]adrenaline and [3H]noradrenaline in various tissues of the Atlantic cod, Gadus morhua. Ungell AL. **Comp Biochem Physiol** [C] 1985;81(1):25-8

Regulation of ketogenesis by epinephrine and norepinephrine in the overnight-fasted, conscious dog. Steiner KE, et al. **Diabetes** 1985 May; 34(5):425-32

Plasma glucagon and catecholamines during exhaustive short-term exercise. Näveri H, et al. **Eur J Applied Physiol** 1985;53(4):308-11

Normetanephrine and metanephrine oxidized by both types of monoamine oxidase. Suzuki O, et al. **Experientia** 1985 May 15;41(5):634-6

Enhancement of adrenaline plasma-levels shortens adrenaline half-life. Porta S, et al. **Horm Metab Res** 1985 May;17(5):264-5

Plasma catecholamine and blood lactate cumulation during incremental exhaustive exercise. Lehmann M, et al. **Int J Sports Med** 1985 Apr; 6(2):78-81

Exercise, dobutamine, and combined atropine, norepinephrine, and epinephrine compared. Haidet GC, et al. **J Appl Physiol** 1985 Jun; 58(6):2047-53

Hemodynamic effects of epinephrine: concentration-effect study in humans. Stratton JR, et al. **J Appl Physiol** 1985 Apr;58(4):1199-206

Analysis of USP epinephrine injections for potency, impurities, degradation products, and d-enantiomer by liquid chromatography, using ultraviolet and electrochemical detectors. Kirchhoefer RD, et al. **J Assoc Off Anal Chem** 1985 Mar-Apr;68(2):163-5

Simple and fast analysis of adrenaline and noradrenaline in plasma on microbore high-performance liquid chromatography columns using fluorimetric detection. Kamperman G, et al. **J Chromatogr** 1985 Feb 8;337(2):384-90

High-performance liquid chromatographic analysis of epinephrine enantiomers using a UV detector in series with an optical activity detector. Scott BS, et al. **J Chromatogr** 1985 Feb 20;319(3):419-26

Circadian rhythms of epinephrine and norepinephrine in man. Linsell CR, et al. **J Clin Endocrinol Metab** 1985 Jun;60(6):1210-5

(-)-Adrenaline-induced, calcium-dependent phosphorylation of proteins in human platelets. Block LH, et al. **J Clin Invest** 1985 May; 75(5):1600-7

Evidence for a beta-adrenoceptor-mediated regulation of human natural killer cells. Hellstrand K, et al. **J Immunol** 1985 Jun;134(6):4095-9

Decrease in hypothalamic epinephrine concentration and other neurochemical changes produced by quinpirole, a dopamine agonist, in rats. Fuller RW, et al. **J Neural Transm** 1985;61(3-4):161-73

Effects of intravenous glucose or epinephrine injection on plasma concentrations of potassium, magnesium and insulin in sheep. Yano H, et al. **J Nutr Sci Vitaminol (Tokyo)** 1984 Dec;30(6):535-40

Review and survey of medicaments used with gingival retraction cords. Donovan TE, et al. **J Prosthet Dent** 1985 Apr;53(4):525-31

Adrenaline, adenosine, and feedback [letter] Böhm M, et al. **Lancet** 1985 May 18;1(8438):1157

Effect of intravenous epinephrine infusion on plasma renin activity in adrenalectomized dogs. Johnson MD. **Life Sci** 1985 Jun 24; 36(25):2403-11

Subsensitive pituitary cyclic AMP response to stress following adrenalectomy is not caused by loss of adrenal epinephrine. Kant GJ, et al. **Life Sci** 1985 Jun 24;36(25):2421-8

Epinephrine and norepinephrine syntheses are regulated by a glucocorticoid receptor-mediated mechanism in the bovine adrenal medulla. Nawata H, et al. **Life Sci** 1985 May 20;36(20):1957-66

The effect of epinephrine and serotonin on hepatic poly(A)+ RNA synthesis. Roy AK, et al. **Life Sci** 1985 Jun 17;36(24):2301-7

Adrenaline and anaphylaxis [letter] Roberts-Thomson P, et al. **Med J Aust** 1985 Jun 24;142(13):708

Excretion of urinary catecholamines and plasma cortisol levels in female nurses on short-rotating shift. Panza G, et al. **Med Lav** 1985 Jan-Feb; 76(1):30-4

Effect of epinephrine on carbohydrate metabolism in exercising dogs. Issekutz B Jr. **Metabolism** 1985 May;34(5):457-64

Plasma catecholamines in arterial and capillary blood. Baumgartner H, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):461-3

Effect of histamine infusion on circulating methionine-enkephalin and catecholamine concentrations. Smith R, et al. **Neurosci Lett** 1985 Apr 19;55(3):289-92

Administering epinephrine in an emergency. Gever LN. **Nursing** 1985 Jun;15(6):65

Dissociation of epinephrine's hyperglycemic and anorectic effect. Langhans W, et al. **Physiol Behav** 1985 Mar;34(3):457-63

Airway responses to low concentrations of adrenaline and noradrenaline in normal subjects. Berkin KE, et al. **Q J Exp Physiol** 1985 Apr; 70(2):203-9

Relationship between sleep efficiency and urinary excretion of catecholamines in bed-rested humans. Nishihara K, et al. **Sleep** 1985; 8(2):110-7

Behavioural and endocrine reactions in boys scoring high on Sennton neurotic scale viewing an exciting and partly violent movie and the importance of social support. Arnetz BB, et al. **Soc Sci Med** 1985; 20(7):731-6

[Effect of adrenaline and phenylephrine on milk extraction during the mechanical milking of cows] Bernabé J, et al. **Reprod Nutr Dev** 1985; 25(2):379-88 (Eng. Abstr.) **(Fre)**

[Animal experiment studies on the hemodynamic effect of adrenaline following intravenous and endobronchial administration] Hörnchen U, et al. **Anasth Intensivther Notfallmed** 1985 Apr;20(2):84-8 (Eng. Abstr.) **(Ger)**

[Electrocardiographic studies of the modification of cardiac activity in cattle by adrenaline and noradrenaline with and without vagolysis (atropine) and beta-receptor blockade (propranolol)] Mielke H, et al. **Arch Exp Veterinarmed** 1985 Mar;39(2):193-206 (Eng. Abstr.) **(Ger)**

[Concentrations of catecholamines in CSF and plasma, and cardiovascular effects following epidural administration of 2 mg epinephrine] Nakajima J. **Masui** 1985 Feb;34(2):144-51 (Eng. Abstr.) **(Jpn)**

[Urinary excretion of catecholamines in children with functional disorders of the digestive system] Szewczyk L, et al. **Pediatr Pol** 1984 Oct; 59(10):835-9 (Eng. Abstr.) **(Pol)**

[Catecholaminergic activity in children with nocturnal enuresis] Szewczyk L. **Pediatr Pol** 1984 Oct;59(10):841-5 (Eng. Abstr.) **(Pol)**

[Regulation of the cell cycle of B-lymphocytes in mice by substances elevating the levels of intracellular cAMP and cGMP] Ado AD, et al. **Biull Eksp Biol Med** 1985 Apr;99(4):455-8 (Eng. Abstr.) **(Rus)**

[Circadian rhythms of adrenaline and noradrenaline excretion in man in normal conditions and after alcohol intake] Latenkov VP. **Biull Eksp Biol Med** 1985 Mar;99(3):344-6 (Eng. Abstr.) **(Rus)**

[Effect of phenazepam on the peripheral catecholaminergic systems in immobilization stress] Malikova LA, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):23-7 (Eng. Abstr.) **(Rus)**

[Changes in adrenaline sensitivity during thermal adaptation] Kosenkov NI. **Fiziol Cheloveka** 1984 May-Jun;10(3):478-9 **(Rus)**

[Effect and aftereffect of adrenaline on the respiration of rat liver mitochondria] Babskii AM, et al. **Fiziol Zh** 1985 May-Jun; 31(3):301-6 (Eng. Abstr.) **(Rus)**

[Effect of resection and dissection of the distal portion of the small intestine on the adrenergic inhibition of gastric secretion] Trefilov AB. **Fiziol Zh SSSR** 1985 Feb;71(2):221-5 (Eng. Abstr.) **(Rus)**

[Normal values of dopamine, noradrenaline, adrenaline, and 5-hydroxyindoleacetic acid in pregnancies of different gestational ages] Lerdo de Tejada A, et al. **Ginecol Obstet Mex** 1985 Feb; 53(334):49-52 (Eng. Abstr.) **(Spa)**

[Radioimmunoanalysis of adrenaline and noradrenaline in the normal fetus at term] Martínez Alcalá FO, et al. **Ginecol Obstet Mex** 1983 Oct; 51(318):267-72 (Eng. Abstr.) **(Spa)**

ESCAPE REACTION

Intracortical glutamate injection produces helpless-like behavior in the rat. Petty F, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):531-3

The activation of mice's behavior and reduction of brain beta-adrenergic receptor binding following repeated administration of antidepressant drugs. Nomura S, et al. **Yakubutsu Seishin Kodo** 1984 Nov; 4(3):237-41

ESTRADIOL

The effects of testosterone and estrogen on the pituitary growth hormone response to growth hormone-releasing factor. Wehrenberg WB, et al. **Biol Reprod** 1985 Mar;32(2):369-75

The possible role of 2-hydroxyestradiol in the development of estrogen-induced striatal dopamine receptor hypersensitivity. Clopton JK, et al. **Brain Res** 1985 Apr 29;333(1):1-10

Estradiol benzoate decreases nigral GABAergic activity in male rats. Nicoletti F, et al. **Brain Res** 1985 Apr 15;332(1):179-83

Estradiol increases dopamine turnover in intermediate and posterior pituitary lobes of ovariectomized rats. Saavedra JM, et al. **Cell Mol Neurobiol** 1984 Dec;4(4):397-402

In vitro and in vivo antagonistic regulation by estradiol and progesterone of the rat pituitary domperidone binding sites: correlation with ovarian steroid regulation of the dopaminergic inhibition of prolactin secretion in vitro. Bression D, et al. **Endocrinology** 1985 May;116(5):1905-11

Longitudinal study of the surge of gonadotropins induced by exogenous hormones in prepuberal gilts. Fleming MW, et al. **Endocrinology** 1985 May;116(5):1893-8

Relation of circulating estradiol and progesterone to gonadotropin secretion and estrous cyclicity in aging female rats. Lu JK, et al. **Endocrinology** 1985 May;116(5):1953-9

Hormonal influence on the response of the uterus of the Brazilian marsupial Didelphis albiventris to adrenergic drugs. Rocha LR, et al. **Gen Comp Endocrinol** 1985 May;58(2):179-85

Levels of dopamine and thyrotrophin-releasing hormone in hypophysial stalk blood during an oestrogen-stimulated surge of prolactin in the ovariectomized rat. de Greef WJ, et al. **J Endocrinol** 1985 Apr; 105(1):107-12

Changes in pulsatile LH secretion and the positive and negative feedback actions of oestradiol after administration of a GnRH agonist in the ovariectomized ewe. Fitzgerald BP, et al. **J Reprod Fertil** 1985 Mar; 73(2):433-40

Neurotensin enhances estradiol induced DNA synthesis in immature rat uterus. Mistry A, et al. **Life Sci** 1985 May 27;36(21):2063-7

Progesterone-induced LHRH release in vitro is an estrogen—as well as Ca++- and calmodulin-dependent secretory process. Drouva SV, et al. **Neuroendocrinology** 1985 Apr;40(4):325-31

Alteration of dopamine metabolism in different brain regions of the rabbit by estradiol and tamoxifen. Baksi SN, et al. **Neuroscience** 1985 Apr; 14(4):1053-9

The effect of chronic estrogen treatment on immunoreactive beta-endorphin levels in intact female rats. Forman LJ, et al. **Proc Soc Exp Biol Med** 1985 Jul;179(3):365-72

[Effect of the administration of thyroxine and estradiol on the morphology of the anterior lobe of the pituitary gland] Szczurek Z, et al. **Patol Pol** 1984 Oct-Dec;35(4):499-507 (Eng. Abstr.) **(Pol)**

ETHOLOGY

Automated measurement of multivariate locomotor behavior in rodents. Sanberg PR, et al. **Neurobehav Toxicol Teratol** 1985 Jan-Feb; 7(1):87-94

EXPLORATORY BEHAVIOR

Response of the rat brain beta-endorphin system to novelty: importance of the fornix connection. Netto CA, et al. **Behav Neural Biol** 1985 Jan; 43(1):37-46

Sulpiride blocks postsynaptic dopamine receptors in the nucleus accumbens. Morgenstern R, et al. **J Neural Transm** 1985; 61(3-4):151-60

Stress produces opioid-like effects on investigatory behavior. Arnsten AF, et al. **Pharmacol Biochem Behav** 1985 May;22(5):803-9

Increased investigative activity after presynaptic dopaminergic stimulation measured by a fixed-interval recording procedure. Höglund AU, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):403-6

Development of mouse activity, stimulus reactivity, habituation, and response to amphetamine and scopolamine. Alleva E, et al. **Physiol Behav** 1985 Apr;34(4):519-23

Behavioral analysis of the effect of neurotensin injected into the ventral mesencephalon on investigatory and spontaneous motor behavior in the rat. Cador M, et al. **Psychopharmacology (Berlin)** 1985;85(2):187-96

[Effect of stable strontium on spontaneous and drug-induced motor activity in the rat] Escanero JF, et al. **Arch Farmacol Toxicol** 1985 Apr; 11(1):33-9 (Eng. Abstr.) **(Spa)**

EXTINCTION (PSYCHOLOGY)

Haloperidol and nonreinforcement produce different patterns of response slowing in a food reinforced runway task. Wirtshafter D, et al. **Pharmacol Biochem Behav** 1985 May;22(5):661-3

FEAR

Imipramine in the treatment of panic disorder and its complications. Liebowitz MR. **Psychiatr Clin North Am** 1985 Mar;8(1):37–47

Anxiolytic drugs and the acquisition of conditioned fear in mice. Sanger DJ, et al. **Psychopharmacology (Berlin)** 1985;85(3):284–8

FENFLURAMINE

Possible relationships between changes in body weight set–point and stress metabolism after treating rats chronically with D–fenfluramine. Effects of feeding rats acutely with fructose on the metabolism of corticosterone, glucose, fatty acids, glycerol and triacylglycerol. Brindley DN, et al. **Biochem Pharmacol** 1985 Apr 15;34(8):1265–71

d–Fenfluramine and salbutamol: two drugs causing anorexia through different neurochemical mechanisms. Garattini S, et al. **Int J Obes** 1984; 8 Suppl 1:151–7

Comparison of the effects of fenfluramine and other anorectic agents in different feeding and drinking paradigms in rats. Rowland NE, et al. **Life Sci** 1985 Jun 17;36(24):2295–300

The effect of previous d–amphetamine treatment on the disposition and lethality of fenfluramine in the rat. Hunsinger RN, et al. **Toxicol Appl Pharmacol** 1985 Jun 30;79(2):236–45

[Ponderal Retard] de Longraye J. **Soins** 1985 Feb;(448):III–IV **(Fre)**

FK 33–824

Effect of dopamine receptor stimulation on the inhibition of LH pulsatility by a met–enkephaline (FK 33–824). del Pozo E, et al. **Acta Neurochir (Wien)** 1985;75(1–4):88–90

FLUPHENAZINE

Priapism resulting from fluphenazine hydrochloride treatment reversed by diphenhydramine. Fishbain DA. **Ann Emerg Med** 1985 Jun; 14(6):600–2

The effects of chronic neuroleptic treatment on neurotensin–like immunoreactivity in the rat central nervous system. Goedert M, et al. **Brain Res** 1985 Jun 3;335(2):334–6

Serum neuroleptic levels and clinical outcome in schizophrenic patients treated with fluphenazine decanoate. Brown WA, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):143–7

Double–blind comparison of haloperidol decanoate and fluphenazine decanoate effectiveness, side–effects, dosage and serum levels during a six months' treatment for relapse prevention. Kissling W, et al. **Pharmacopsychiatry** 1985 May;18(3):240–5

Serum and cerebrospinal fluid prolactin patterns during neuroleptic treatment in schizophrenic patients. Rimón R, et al. **Pharmacopsychiatry** 1985 May;18(3):252–4

Effects of thioridazine and fluphenazine on the pituitary, thyroid and adrenal functions in patients with paranoid schizophrenia. Horodnicki JM, et al. **Psychiatr Pol** 1984 May–Jun;18(3):205–11

[Social integration of long–term paraphrenic patients with low–dose depot neuroleptic medication] Lesch OM, et al. **Psychiatr Prax** 1985 Mar; 12(2):63–8 (Eng. Abstr.) **(Ger)**

FLURAZEPAM

GABA and benzodiazepine–induced modification of [14C]L–glutamic acid release from rat spinal cord slices. Vellucci SV, et al. **Brain Res** 1985 Mar 25;330(2):201–7

Benzodiazepines inhibit human platelet activation: comparison of the mechanism of antiplatelet actions of flurazepam and diazepam. Romstedt K, et al. **Thromb Res** 1985 May 15;38(4):361–74

FOOD DEPRIVATION

Effect of feed and water deprivation or force–feeding on plasma prolactin concentration in turkey hens. Zadworny D, et al. **Biol Reprod** 1985 Mar;32(2):241–7

Ontogenetic alterations in the effects of food and/or maternal deprivation on 5–HT, 5–HIAA and 5–HIAA/5–HT ratios. Spear LP, et al. **Brain Res** 1985 Feb;350(1–2):143–57

FSH

Possible site of negative and positive feedback action of oestrogen on gonadotrophin secretion in normal women. Nagahara Y, et al. **Acta Endocrinol (Copenh)** 1985 Apr;108(4):440–4

Long–term, pulsatile, low dose, subcutaneous luteinizing hormone–releasing hormone administration in men with idiopathic oligozoospermia. Failure of therapeutic and hormonal response. Fauser BC, et al. **Andrologia** 1985 Mar–Apr;17(2):143–9

Changes in the isoelectric focusing profile of pituitary follicle–stimulating hormone in the developing male rat. Chappel SC, et al. **Biol Reprod** 1985 Apr;32(3):567–73

Dose–dependent inhibition of the preovulatory surges of gonadotropins and prolactin by the antiestrogen CI–628: possible sites of action. De Paolo LV. **Biol Reprod** 1985 May;32(4):745–52

Effect of gonadotropin–releasing hormone antagonists on serum follicle–stimulating hormone and luteinizing hormone under conditions of singular follicle–stimulating hormone secretion. Schwartz NB, et al. **Biol Reprod** 1985 Mar;32(2):391–8

Longitudinal study of the surge of gonadotropins induced by exogenous hormones in prepuberal gilts. Fleming MW, et al. **Endocrinology** 1985 May;116(5):1893–8

Follicle–stimulating hormone induction of Leydig cell maturation. Kerr JB, et al. **Endocrinology** 1985 Jun;116(6):2592–604

Relation of circulating estradiol and progesterone to gonadotropin secretion and estrous cyclicity in aging female rats. Lu JK, et al. **Endocrinology** 1985 May;116(5):1953–9

Release of luteinizing hormone and follicle–stimulating hormone from pituitaries of lactating rats by gonadotropin–releasing hormone and high potassium concentration. Smith MS. **Endocrinology** 1985 May; 116(5):1826–34

Cytochemical and cytophysiological studies of gonadotropin–releasing hormone (GnRH) target cells in the male rat pituitary: differential effects of androgens and corticosterone on GnRH binding and gonadotropin release. Tibolt RE, et al. **Endocrinology** 1985 Jul;117(1):396–404

FSH and LH response to testosterone and gonadotropin–releasing hormone in aging male rats. Sartin JL, et al. **Exp Aging Res** 1984 Winter; 10(4):183–7

Effects of short–term exposure to catecholestrogens on serum concentrations of gonadotrophins and metabolism of catecholestrogens in ovariectomized rats. Ball P, et al. **Horm Metab Res** 1985 Apr; 17(4):184–8

Effect of castration and steroid treatment on the release of gonadotropins by the rat pituitary–hypothalamus complex in vitro. Gill MK, et al. **Horm Metab Res** 1985 Mar;17(3):141–6

Hormonal responses to short term fasting in postmenopausal women. Beitins IZ, et al. **J Clin Endocrinol Metab** 1985 Jun;60(6):1120–6

Heterogeneity of rat FSH by chromatofocusing: studies on serum FSH, hormone released in vitro and metabolic clearance rates of its various forms. Blum WF, et al. **J Endocrinol** 1985 Apr;105(1):29–37

Routine measurement of thyroid hormones and FSH in infertility not worthwhile [letter] Conway DI, et al. **Lancet** 1985 Apr 27; 1(8435):977–8

Differential suppression of follicle–stimulating hormone and luteinizing hormone secretion in vivo by a gonadotropin–releasing hormone antagonist. Grady RR, et al. **Neuroendocrinology** 1985 Mar; 40(3):246–52

[Activity of clobazam on plasma prolactin and gonadotropins after administration of sulpiride in the male rat] Valli M, et al. **Ann Endocrinol (Paris)** 1984;45(6):409–11 (Eng. Abstr.) **(Fre)**

GABA

Respiratory depression produced by injection of GABA into the fourth ventricle of the rabbit. Xiang JZ, et al. **Acta Acad Med Wuhan** 1985; 5(1):10–4

Inhibition of anaphylactic histamine release in vitro by GABA. Luzzi S, et al. **Agents Actions** 1985 Apr;16(3–4):160–2

The modulation of acetylcholine release by noradrenaline, GABA and related compounds. Beani L, et al. **Ann Ist Super Sanita** 1984; 20(1):17–9

Selectivity of [3H] GABA uptake and release in cells cultured from the rat cerebellum. Levi G, et al. **Ann Ist Super Sanita** 1984;20(1):39–45

Drugs acting as modulators of neurochemical mechanisms of gabaergic synaptic transmission. Rayevsky KS, et al. **Ann Ist Super Sanita** 1984; 20(1):47–52

GABA effect on conditioned reflex responses in teleost. Ivanuš J, et al. **Ann NY Acad Sci** 1985;444:543–6

Inhibitory effect of GABA on sympathetic neurotransmission in rabbit ear artery. Manzini S, et al. **Arch Int Pharmacodyn Ther** 1985 Jan; 273(1):100–9

Response of the cockroach brain gamma–aminobutyric acid system to isonicotinic acid hydrazide and mercaptopropionic acid. Pandey A, et al. **Biochem Int** 1985 Feb;10(2):213–20

In vivo effects of aminooxyacetic acid and valproic acid on nerve terminal (synaptosomal) GABA levels in discrete brain areas of the rat. Correlation to pharmacological activities. Löscher W, et al. **Biochem Pharmacol** 1985 May 15;34(10):1747–56

gamma–Aminobutyric acid–mediated inhibition at cholinergic synapses formed by cultured retinal neurons. Agardh E, et al. **Brain Res** 1985 Mar 25;330(2):323–8

Subchronic administration of GABAergic agonists elevates [3H]GABA binding and produces tolerance in striatal dopamine catabolism. Beart PM, et al. **Brain Res** 1985 May 27;335(1):169–73

Effects of inhibitors of Na+,K+–ATPase on the membrane potentials and neurotransmitter efflux in rat brain slices. Brosemer RW. **Brain Res** 1985 May 13;334(1):125–37

Effects of glycine and GABA on the ganglion cels of the retina of the skate Raja erinacea. Cohen JL. **Brain Res** 1985 Apr 15; 332(1):169–73

Chemical activation of the mesencephalic locomotor region. Garcia-Rill

E, et al. **Brain Res** 1985 Mar 18;330(1):43-54

Immunohistochemistry of gamma-aminobutyric acid in the cat nucleus tractus solitarius. Maley B, et al. **Brain Res** 1985 Mar 25; 330(2):364-8

Effect of GABA and its antagonists, bicuculline and picrotoxin, on nerve cell discharges of the photosensory pineal organ of the frog, Rana esculenta. Meissl H, et al. **Brain Res** 1985 Apr 15;332(1):39-46

Specific [3H]gamma-aminobutyric acid binding to vestibular membranes of the chick inner ear. Meza G, et al. **Brain Res** 1985 Jun 24; 337(1):179-83

Estradiol benzoate decreases nigral GABAergic activity in male rats. Nicoletti F, et al. **Brain Res** 1985 Apr 15;332(1):179-83

Inhibitory influence of GABA on central serotonergic transmission. Involvement of the habenulo-raphé pathways in the GABAergic inhibition of ascending cerebral serotonergic neurons. Nishikawa T, et al. **Brain Res** 1985 Apr 1;331(1):81-90

Inhibitory influence of GABA on central serotonergic transmission. Raphé nuclei as the neuroanatomical site of the GABAergic inhibition of cerebral serotonergic neurons. Nishikawa T, et al. **Brain Res** 1985 Apr 1;331(1):91-103

The development of the dorsal root potential and the responsiveness of primary afferent fibers to gamma-aminobutyric acid in the spinal cord of rat fetuses. Seno N, et al. **Brain Res** 1985 Jan;349(1-2):11-6

Identified axo-axonic cells are immunoreactive for GABA in the hippocampus and visual cortex of the cat. Somogyi P, et al. **Brain Res** 1985 Apr 15;332(1):143-9

Synthesis of acetylcholine and gamma-aminobutyric acid by dissociated cerebral cortical cells in vitro. Thomas WE. **Brain Res** 1985 Apr 15; 332(1):79-89

GABA and benzodiazepine-induced modification of [14C]L-glutamic acid release from rat spinal cord slices. Vellucci SV, et al. **Brain Res** 1985 Mar 25;330(2):201-7

Neurochemical studies of the nucleus of the solitary tract, dorsal motor nucleus of the vagus and the hypoglossal nucleus in rat: topographical distribution of glutamate uptake, GABA uptake and glutamic acid decarboxylase activity. Simon JR, et al. **Brain Res Bull** 1985 Jan; 14(1):49-53

Interaction of penicillin and pentobarbital with inhibitory synaptic mechanisms in neocortex. Weiss DS, et al. **Cell Mol Neurobiol** 1984 Dec;4(4):301-17

Inhibition of central angiotensin II induced drinking by GABA in the rat. Hutchinson JS, et al. **Clin Exp Hypertens** [A] 1984; 6(10-11):1777-80

Gamma aminobutyric acid (GABA) and hepatic bile flow in the adult rat. Minuk GY, et al. **Clin Invest Med** 1984;7(4):193-7

Comparative actions of GABA and acetylcholine on the Xenopus laevis lateral line. Bobbin RP, et al. **Comp Biochem Physiol** [C] 1985; 80(2):313-8

gamma-Amino butyric-N-acid sensitivity of mouse and human oocytes. Dolci S, et al. **Dev Biol** 1985 May;109(1):242-6

Study of ocular tissue changes, brain GABA and polyamine levels in rats exposed to carbon disulfide. Sefić M, et al. **G Ital Med Lav** 1984 May-Jul;6(3-4):127-9

GABA-ergic system in brain regions of glutamate-lesioned rats. Di Giorgio RM, et al. **Ital J Biochem** 1985 Jan-Feb;34(1):19-28

GABA neurons in the superficial layers of the rat dorsal cochlear nucleus: light and electron microscopic immunocytochemistry. Mugnaini E. **J Comp Neurol** 1985 May 1;235(1):61-81

Orally active and potent inhibitors of gamma-aminobutyric acid uptake. Ali FE, et al. **J Med Chem** 1985 May;28(5):653-60

gamma-Aminobutyric acid: temperature dependence in benzodiazepine receptor binding. Chweh AY, et al. **J Neurochem** 1985 Jul; 45(1):240-3

Modulation of the acetylcholine system in the superior cervical ganglion of rat: effects of GABA and hypoglossal nerve implantation after in vivo GABA treatment. Kása P, et al. **J Neurochem** 1985 May; 44(5):1363-72

A description of the GABAergic neurons and axon terminals in the motor nuclei of the cat thalamus. Kultas-Ilinsky K, et al. **J Neurosci** 1985 May;5(5):1346-69

A specific and sensitive determination of gamma aminobutyric acid in CSF and brain tissue by gas chromatography-mass spectrometry. Schaaf JM, et al. **J Neurosci Methods** 1985 May;13(3-4):257-65

GABAergic inhibition of hypertonic saline-induced vasopressin-dependent hypertension. Brennan TJ, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):663-71

Evidence for gamma-aminobutyric acid mediation of the sympathetic nerve inhibitory response to vagal afferent stimulation. Humphrey SJ, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):288-97

Possible inhibitory role of endogenous gamma-aminobutyric acid in the nonnicotinic functions of the dog cardiac sympathetic ganglia. Kushiku K, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):810-5

gamma-Aminobutyric-acid- and pentobarbitone-gated chloride currents in internally perfused frog sensory neurones. Akaike N, et al. **J Physiol (Lond)** 1985 Mar;360:367-86

Comparison of the action of baclofen with gamma-aminobutyric acid on rat hippocampal pyramidal cells in vitro. Newberry NR, et al. **J Physiol (Lond)** 1985 Mar;360:161-85

Effects of calcium hopantenate on neurotransmitter receptors in the rat brain. Ogawa N, et al. **Jpn J Pharmacol** 1985 Jan;37(1):45-50

Inhibitory effect on 3H-diazepam binding and potentiating action on GABA of ethyl loflazepate, a new minor tranquilizer. Sakai Y, et al. **Jpn J Pharmacol** 1985 Apr;37(4):373-9

The use of 3H-gamma-aminobutyric acid for transport studies with isolated nerve-terminals from rat brain. Halvarsson GB, et al. **Life Sci** 1985 Jul 22;37(3):209-16

Uptake of gamma-aminobutyric acid by human blood platelets: comparison with CNS uptake. Hambley JW, et al. **Life Sci** 1985 May 27;36(21):2053-62

Comparison of the pharmacological and biochemical profiles of valproic acid (VPA) and its cerebral metabolite (2-en-VPA) after oral administration in mice. Keane PE, et al. **Methods Find Exp Clin Pharmacol** 1985 Feb;7(2):83-6

Comparison of release of endogenous dopamine and gamma-aminobutyric acid from rat caudate synaptosomes. Caudill WL, et al. **Neurochem Res** 1985 Mar;10(3):319-31

Cimetidine-induced prolactin release: possible involvement of the GABA-ergic system. Sibilia V, et al. **Neuroendocrinology** 1985 Mar; 40(3):189-92

Chronic valproic acid therapy and synaptic markers of amino acid neurotransmission. Slevin JT, et al. **Neurology** 1985 May; 35(5):728-31

A GABAergic component in homosynaptic depression in the spinal monosynaptic pathway. A requirement for action of benzodiazepines. Davies MF, et al. **Neuropharmacology** 1985 Apr;24(4):309-16

Inhibitory effect of cholesteryl gamma-aminobutyrate on evoked activity in rat hippocampal slices. Hesse GW, et al. **Neuropharmacology** 1985 Feb;24(2):139-46

Parallel changes in the sensitivity of gamma-aminobutyric acid and noradrenergic receptors following chronic administration of antidepressant and GABAergic drugs. A possible role in affective disorders. Suzdak PD, et al. **Neuropharmacology** 1985 Mar; 24(3):217-22

The modulation of cortical acetylcholine release by GABA, GABA-like drugs and benzodiazepines in freely moving guinea-pigs. Tanganelli S, et al. **Neuropharmacology** 1985 Apr;24(4):291-9

gamma-Aminobutyric acid modulation of benzodiazepine receptor binding in vitro does not predict the pharmacologic activity of all benzodiazepine receptor ligands. Chweh AY, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):173-7

gamma-Aminobutyric acid enables synaptogenesis in the intact superior cervical ganglion of the adult rat. Dames W, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):159-64

gamma-Aminobutyric acid-induced depression of calcium currents of chick sensory neurons. Deisz RA, et al. **Neurosci Lett** 1985 May 14; 56(2):205-10

gamma-Aminobutyric acid decreases levels of messenger ribonucleic acid encoding prolactin in the rat pituitary. Loeffler JP, et al. **Neurosci Lett** 1985 Jan 7;53(1):121-5

gamma-Aminobutyric acid partly mediates the pentobarbitone depression of synaptic excitation in the guinea-pig olfactory cortex in vitro. Steel L, et al. **Neurosci Lett** 1985 May 1;56(1):33-8

Autoreceptors regulate gamma-[3H]aminobutyric acid release from the guinea pig small intestine. Taniyama K, et al. **Neurosci Lett** 1985 Apr 9;55(2):245-8

Distribution, ontogeny and projections of cholecystokinin-8, vasoactive intestinal polypeptide and gamma-aminobutyrate-containing neuron systems in the rat spinal cord: an immunohistochemical analysis. Fuji K, et al. **Neuroscience** 1985 Mar;14(3):881-94

Effects of octopamine on GABA-ergic transmission in rats. Jagiello-Wójtowicz E, et al. **Pol J Pharmacol Pharm** 1984 Nov-Dec; 36(6):595-601

Influence of GABA mimetics and lithium on biochemical manifestations of striatal dopamine target cell hypersensitivity. Scatton B, et al. **Psychopharmacology [Suppl]** 1985;2:39-45

Actions of GABA and ethylenediamine on CA1 pyramidal neurones of the rat hippocampus. Blaxter TJ, et al. **Q J Exp Physiol** 1985 Jan; 70(1):75-93

Somatostatin and GABA correlate with cervical autonomic nerve activity. Tonoue T, et al. **Regul Pept** 1985 Apr;10(4):299-307

[Pre-synaptic inhibition and pentobarbital] Ohmura Y. **Masui** 1985 Jan; 34(1):2-8 (36 ref.) **(Jpn)**

[Drug activation of GABAergic transmission in the central nervous system: benzodiazepines and GABAergic agonists] Moura D, et al. **Acta Med Port** 1985 Feb;6(2):57-64 (46 ref.) (Eng. Abstr.) **(Por)**

[Action of neurotropic substances on gamma-aminobutyric acid release from brain synaptosomes during K+ depolarization] Maisov NI, et al. **Biull Eksp Biol Med** 1985 Apr;99(4):451-3 (Eng. Abstr.) **(Rus)**

[Participation of gamma-aminobutyric acid in regulating corticotropin secretion in rats] Mishunina TM, et al. **Fiziol Zh** 1985 May-Jun; 31(3):321-6 (Eng. Abstr.) **(Rus)**

[Effects of microinjections of GABA into structures of the medulla oblongata on cardio- and hemodynamics indices] Shapoval LN, et al. **Fiziol Zh** 1985 Mar-Apr;31(2):219-23 **(Rus)**

[Effect of gamma-aminobutyric acid, taurine and catecholamines on the synaptic processes in Lorenzini's ampules in Black Sea skates] Akoev GN, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):466-71 (Eng. Abstr.) **(Rus)**

[Effect of hypothermia on reuptake of neuromediators by synaptosomes] Babiichuk GA, et al. **Ukr Biokhim Zh** 1985 Mar-Apr;57(2):87-9 (Eng. Abstr.) **(Rus)**

GLUCURONIDASE

Assay of beta-glucuronidase in bile following ion-pair extraction of pigments and bile acids. Kurtin WE, et al. **Anal Biochem** 1985 Jun; 147(2):511-6

beta-Glucuronidase activities of intestinal bacteria determined both in vitro and in vivo in gnotobiotic rats. Gadelle D, et al. **Appl Environ Microbiol** 1985 Mar;49(3):682-5

Evaluation and modification of spectrophotometric procedures for analysis of lactate dehydrogenase, beta-glucuronidase and arylsulphatase in human gingival crevicular fluid collected with filter-paper strips. Lamster IB, et al. **Arch Oral Biol** 1985; 30(3):235-42

Glucuronidase activity in Escherichia coli [letter] Nastasi A, et al. **Boll Ist Sieroter Milan** 1982;61(5):441

Human hepatic beta-glucuronidase: an enzyme kinetic study. Ho YC, et al. **Enzyme** 1985;33(1):9-17

Oligosaccharides generated by an endoglucuronidase are intermediates in the intracellular degradation of heparan sulfate proteoglycans. Kjellén L, et al. **J Biol Chem** 1985 Jul 15;260(14):8416-22

Effects of ammonia on processing and secretion of precursor and mature lysosomal enzyme from macrophages of normal and pale ear mice: evidence for two distinct pathways. Brown JA, et al. **J Cell Biol** 1985 Jun;100(6):1894-904

Lactate dehydrogenase, beta-glucuronidase and arylsulfatase activity in gingival crevicular fluid associated with experimental gingivitis in man. Lamster IB, et al. **J Periodontol** 1985 Mar;56(3):139-47

Nucleotide sequence of a regulatory region of the uidA gene in Escherichia coli K12. Blanco C, et al. **MGG** 1985;199(1):101-5

Mutagenicity of beta-glucuronidase in the Ames test. Cerná M. **Mutat Res** 1985 Jul;143(3):169-72

Enzyme histochemistry of the response by naive and sensitised macrophages to phagocytosis of collagen and latex particles. Pugh DI, et al. **Z Mikrosk Anat Forsch** 1985;99(1):14-24

GONADOTROPINS, PITUITARY

Hypothalamic gonadotrophin-releasing hormone and pituitary and plasma FSH and prolactin during photostimulation and photorefractoriness in intact and thyroidectomized starlings (Sturnus vulgaris). Dawson A, et al. **J Endocrinol** 1985 Apr;105(1):71-7

[Effect of veralipride on LH, FSH, and PRL levels and on the climacteric syndrome] De Cecco L, et al. **Rev Fr Gynecol Obstet** 1985 Feb 28; 80(3):152-5 (Eng. Abstr.) **(Fre)**

[Effect of preventive administration of lithium carbonate on serum concentrations of various pituitary and peripheral hormones in patients with endogenous depression] Horodnicki JM, et al. **Psychiatr Pol** 1984 Jul-Aug;18(4):319-25 (Eng. Abstr.) **(Pol)**

GUANETHIDINE

Guanethidine blocks the 2-deoxy-D-glucose-induced hypothalamic noradrenergic drive to hyperglycemia. Storlien LH, et al. **Brain Res** 1985 May 27;335(1):144-7

HABITUATION (PSYCHOPHYSIOLOGY)

Habituation to repeated stress is stressor specific. Kant GJ, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):631-4

HALOPERIDOL

Rapid formation of reduced haloperidol in guinea pigs following haloperidol administration. Korpi ER, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 Feb;56(2):94-8

The interpretation of plasma haloperidol concentrations. Kirch DG, et al. **Arch Gen Psychiatry** 1985 Aug;42(8):838-40

Plasma haloperidol levels: clinical response and fancy mathematics [letter] Van Putten T, et al. **Arch Gen Psychiatry** 1985 Aug;42(8):835-8

Ontogeny of striatal unit activity and effects of single or repeated haloperidol administration in rats. Napier TC, et al. **Brain Res** 1985 Apr 29;333(1):35-44

Possible interactions between dynorphin and dopaminergic systems in rat basal ganglia and substantia nigra. Quirion R, et al. **Brain Res** 1985 Apr 8;331(2):358-62

Effect of duration of haloperidol treatment on DA receptor supersensitization in aging C57BL/6J mice. Randall PK, et al. **Brain Res** 1985 Apr 29;333(1):85-95

Chronic haloperidol does not alter agonist affinity for dopamine receptors in vitro. Meller E, et al. **Eur J Pharmacol** 1985 Mar 12; 109(3):389-94

The supersensitivity of dopaminergic neurons to apomorphine in rats following chronic haloperidol. Vogelsang GD, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):267-9

Modulation of striatal enkephalinergic neurons by antipsychotic drugs. Hong JS, et al. **Fed Proc** 1985 Jun;44(9):2535-9

Comparison of chlorpromazine, haloperidol and pimozide in the treatment of phencyclidine psychosis: DA-2 receptor specificity. Giannini AJ, et al. **J Toxicol Clin Toxicol** 1984-85;22(6):573-9

Effect of chronic haloperidol and quinacrine coadministration on striatal HVA levels and stereotypic behaviors in response to apomorphine in the rat. Deutsch SI, et al. **Neurochem Res** 1985 Apr;10(4):491-8

Influence of acute, subchronic and chronic treatment with neuroleptic (haloperidol) on enkephalins and their precursors in the striatum of rat brain. Blanc D, et al. **Neuropeptides** 1985 Feb;5(4-6):567-70

Beta-endorphin processing in pituitary and brain is sensitive to haloperidol stimulation. Ham J, et al. **Neuropeptides** 1985 Feb;5(4-6):497-500

Alterations in dopamine metabolism after chronic administration of haloperidol. Possible role of increased autoreceptor sensitivity. Saller CF, et al. **Neuropharmacology** 1985 Feb;24(2):123-9

Effect of haloperidol and sulpiride on dopamine metabolism in nucleus accumbens and olfactory tubercle: a study by in vivo voltammetry. Louilot A, et al. **Neuroscience** 1985 Mar;14(3):775-82

Haloperidol and nonreinforcement produce different patterns of response slowing in a food reinforced runway task. Wirtshafter D, et al. **Pharmacol Biochem Behav** 1985 May;22(5):661-3

Double-blind comparison of haloperidol decanoate and fluphenazine decanoate effectiveness, side-effects, dosage and serum levels during a six months' treatment for relapse prevention. Kissling W, et al. **Pharmacopsychiatry** 1985 May;18(3):240-5

Lateral ventricular enlargement and clinical response in schizophrenia. Smith RC, et al. **Psychiatry Res** 1985 Mar;14(3):241-53

Effect of benztropine on the diurnal prolactin responses to haloperidol. Nathan RS, et al. **Psychoneuroendocrinology** 1985;10(1):71-6

Effects of apomorphine and haloperidol on 'spontaneous' stereotyped licking behaviour in the Cebus monkey. Korsgaard S, et al. **Psychopharmacology (Berlin)** 1985;85(2):240-3

Chronic haloperidol during development attenuates dopamine autoreceptor function in striatal and mesolimbic brain regions of young and older adult rats. Scalzo FM, et al. **Psychopharmacology (Berlin)** 1985;85(3):271-6

The discriminative stimulus properties and detection thresholds of intracranial self-stimulation: effects of d-amphetamine, morphine, and haloperidol. Schaefer GJ, et al. **Psychopharmacology (Berlin)** 1985; 85(3):289-94

Behavioral effects of long-term neuroleptic treatment in Cebus monkeys. Casey DE. **Psychopharmacology [Suppl]** 1985;2:211-6

Differential alteration of striatal D-1 and D-2 receptors induced by the long-term administration of haloperidol, sulpiride or clozapine to rats. Jenner P, et al. **Psychopharmacology [Suppl]** 1985;2:174-81

[Effects of haloperidol, chlorpromazine, metoclopramide and ascorbic acid on adrenergic salivation and lacrimation in mice at an ambient temperature of 30 degrees C] Li BH, et al. **Chung Kuo Yao Li Hsueh Pao** 1985 Mar;6(1):24-6 (Eng. Abstr.) **(Chi)**

[Bilateral dislocation of mandibular joints induced by haloperidol therapy--a case report] Liu ZZ. **Ssu Chuan I Hsueh Yuan Hsueh Pao** 1985 Mar;16(1):82-3 (Eng. Abstr.) **(Chi)**

[Continuous suppression of methamphetamine-induced supersensitivity by chronic haloperidol administration] Kashihara K, et al. **Seishin Shinkeigaku Zasshi** 1984;86(11):928-32 **(Jpn)**

[Role of serotonin and dopamine receptors in the mechanism of action of haloperidol and pirenperone] Maimets MO, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):15-8 (Eng. Abstr.) **(Rus)**

[Haloperidol decanoate in replacing combinations of antipsychotic agents in the treatment of chronic schizophrenics] Youssef HA. **Acta Psiquiatr Psicol Am Lat** 1984 Dec;30(4):297-304 **(Spa)**

[Malignant syndrome caused by neuroleptics. Rapid response to biperiden in a case of brief development (letter)] Castilla Cortázar A, et al. **Med Clin (Barc)** 1985 Apr 13;84(14):588 **(Spa)**

[Influence of nutritional status on intravenous pharmacokinetics of haloperidol in psychotic patients] Donoso A, et al. **Rev Med Chil** 1984 Aug;112(8):777-83 (Eng. Abstr.) **(Spa)**

HISTAMINE

Alteration of histamine metabolism in the rat brain under influence of various antidepressive treatments. Zawilska J, et al. **Agents Actions** 1985 Apr;16(3-4):105-8

Acetylcholine and histamine interact supra-additively on bronchomotor tone in guinea-pigs in vivo: a possible consequence of the relationship between airways resistance and calibre. Stewart AG, et al. **Arch Int Pharmacodyn Ther** 1985 Jan;273(1):33-46

Effect of secretagogues on pancreatic exocrine secretion in the monkey and the dog. Iwatsuki K, et al. **Clin Exp Pharmacol Physiol** 1985 Jan–Feb;12(1):67–72

Involvement of H1– and H2–receptors in triple response to histamine in human volunteers. Patwardhan MD, et al. **Indian J Physiol Pharmacol** 1984 Oct–Dec;28(4):335–7

Vasoactive amines modulate actin cables (stress fibers) and surface area in cultured bovine endothelium. Welles SL, et al. **J Cell Physiol** 1985 Jun;123(3):337–42

Effect of Ni2+ on the multiphasic positive inotropic responses to histamine mediated by H1–receptors in left atria of guinea pigs. Hattori Y, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):188–94

Effect of histamine infusion on circulating methionine–enkephalin and catecholamine concentrations. Smith R, et al. **Neurosci Lett** 1985 Apr 19;55(3):289–92

Possible involvement of central adrenergic and histaminergic systems in clonidine–induced inhibition of pinna reflex. Singh PP, et al. **Pharmacol Res Commun** 1985 Mar;17(3):261–9

Chemical mediators and the human heart. Marone G, et al. **Prog Biochem Pharmacol** 1985;20:38–54 (52 ref.)

[The effect of acetylcholine and histamine on blood flow through the abdominal organs] Antal J, et al. **Bratisl Lek Listy** 1985 Mar; 83(3):218–28 (Eng. Abstr.) **(Slo)**

HUNGER

The anorectic effect of satietin is unrelated to carbohydrate metabolism. Gyarmati S, et al. **Physiol Behav** 1985 Feb;34(2):167–70

HYDANTOINS

Synthesis of side chain–protected amino acid phenylthiohydantoins and their use in quantitative solid–phase Edman degradation. Steiman DM, et al. **Anal Biochem** 1985 Feb 15;145(1):91–5

Genetic polymorphism of mephenytoin p(4')–hydroxylation: difference between Orientals and Caucasians. Jurima M, et al. **Br J Clin Pharmacol** 1985 Apr;19(4):483–7

Mephenytoin metabolism in vitro by human liver. Jurima M, et al. **Drug Metab Dispos** 1985 Mar–Apr;13(2):151–5

Isocratic separation of PTH–amino acids at picomole level by reverse–phase HPLC in the presence of sodium dodecylsulfate. Tsunasawa S, et al. **J Biochem (Tokyo)** 1985 Feb;97(2):701–4

Effect of structural modification of the hydantoin ring on anticonvulsant activity. Cortes S, et al. **J Med Chem** 1985 May;28(5):601–6

HYDRAZINES

Blot analyses of glycoconjugates: enzyme–hydrazide—a novel reagent for the detection of aldehydes. Gershoni JM, et al. **Anal Biochem** 1985 Apr; 146(1):59–63

Separation of dansyl hydrazine–derivatized oligosaccharides by liquid chromatography. Hull SR, et al. **Anal Biochem** 1985 Apr; 146(1):143–9

Enhancement of the horseradish peroxidase–catalyzed chemiluminescent oxidation of cyclic diacyl hydrazides by 6–hydroxybenzothiazoles. Thorpe GH, et al. **Anal Biochem** 1985 Feb 15;145(1):96–100

Phosphorus–nitrogen compounds. 26. Phosphaminimides. 2. 2,2'–Phosphinylidenebis(1,1,1–trimethylhydrazinium) iodide inner salts as agents affecting ganglionic transmission. Cates LA, et al. **J Med Chem** 1985 May;28(5):595–7

Effects of rifampicin and phenobarbital on the fate of isoniazid and hydrazine in vivo in rats. Noda A, et al. **Toxicol Lett** 1985 Jun; 25(3):313–7

HYDROXYBUTYRATES

Identification and quantitation of 1,4–butanediol in mammalian tissues: an alternative biosynthetic pathway for gamma–hydroxybutyric acid. Barker SA, et al. **Biochem Pharmacol** 1985 May 15;34(10):1849–52

Natural occurrence of trans–gamma hydroxycrotonic acid in rat brain. Vayer P, et al. **Biochem Pharmacol** 1985 Jul 1;34(13):2401–4

Effects of endogenous sugar acids on the ventromedial hypothalamic nucleus of the rat. Puthuraya KP, et al. **Brain Res** 1985 Apr 15; 332(1):165–8

Plasma levels of glucose, alanine, lactate, and beta–hydroxybutyrate in the unfed spiny dogfish shark (Squalus acanthias) after surgery and following mammalian insulin infusion. deRoos R, et al. **Gen Comp Endocrinol** 1985 Apr;58(1):28–43

Effects of propionate and methylmalonate on conversions of acetate, butyrate, and D(–)–3–hydroxybutyrate to fatty acids and carbon dioxide by mammary tissue slices of goats. Emmanuel B, et al. **J Dairy Sci** 1985 Mar;68(3):751–4

The effects of mild congenital methylmercury intoxication on the metabolism of 3–hydroxybutyrate and glucose in the brains of suckling rats. Menon NK, et al. **Neurotoxicology (Little Rock Ar)** 1985 Spring; 6(1):55–61

Ketone kinetics and D–(–)–3–hydroxybutyrate–induced inhibition of feeding in rats. Langhans W, et al. **Physiol Behav** 1985 Apr; 34(4):579–82

Effects of hyperketonemia on mouse embryonic and fetal glucose metabolism in vitro. Horton WE Jr, et al. **Teratology** 1985 Apr; 31(2):227–33

HYDROXYDOPAMINES

Effects of intraventricular injections of 6–hydroxydopamine on amine metabolites in rat brain and urine. Edwards DJ, et al. **Biochem Pharmacol** 1985 Apr 15;34(8):1255–63

6–OHDA lesions of the ventral tegmental area block morphine–induced but not amphetamine–induced facilitation of self–stimulation. Hand TH, et al. **Brain Res** 1985 Mar 4;328(2):233–41

Neonatal 6–hydroxydopamine lesion of spinal norepinephrine terminals fails to affect the ontogeny of swimming behavior. Ryan C, et al. **Brain Res** 1985 Jan;349(1–2):258–62

Effect of intracerebroventricular 6–hydroxydopamine (6–HODA) on the angiotensinogen concentration of the brain. Basso N, et al. **Clin Exp Hypertens [A]** 1984;6(10–11):1773–6

Meningeal cells are involved in foliation, lamination, and neurogenesis of the cerebellum: evidence from 6–hydroxydopamine–induced destruction of meningeal cells. Pehlemann FW, et al. **Dev Biol** 1985 Jul;110(1):136–46

Selective destruction of meningeal cells by 6–hydroxydopamine: a tool to study meningeal–neuroepithelial interaction in brain development. Sievers J, et al. **Dev Biol** 1985 Jul;110(1):127–35

Effects of 6–hydroxydopamine–induced catecholamine depletion on shock–precipitated wall climbing of infant rat pups. Emerich DF, et al. **Dev Psychobiol** 1985 May;18(3):215–27

Effects of chemical sympathectomy with 6–hydroxydopamine on cardiac output and its distribution in the rat. Nichols AJ, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):263–8

Effects of intracerebroventricular 6–hydroxydopamine on catecholaminergic fibers in the rat hypothalamus. Hwang BH, et al. **Exp Neurol** 1985 May;88(2):336–48

Cardiovascular effects of intracisternal 6–hydroxydopamine and of subsequent lesions of the ventrolateral medulla coinciding with the A1 group of noradrenaline cells in the rabbit. Elliott JM, et al. **J Auton Nerv Syst** 1985 Feb–Mar;12(2–3):117–30

Rapid changes in synaptic vesicle cytochemistry after depolarization of cultured cholinergic sympathetic neurons. Johnson MI, et al. **J Cell Biol** 1985 Jul;101(1):217–26

Neonatal 6–hydroxydopamine destroys spinal cord noradrenergic axons from the locus coeruleus, but not those from lateral tegmental cell groups. McBride RL, et al. **J Comp Neurol** 1985 May 15; 235(3):375–83

Cardiac postjunctional supersensitivity to beta–agonists after chronic chemical sympathectomy with 6–hydroxydopamine. Chess–Williams RG, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):162–6

6–Hydroxydopamine pretreatment effects on alpha– and beta–adrenergic receptor adaptation to clorgyline. Cohen RM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):158–61

Effects of intravenously administered 6–hydroxydopamine on the content of monoamines in the median eminence and neurointermediate lobe of the rat. Sheward WJ, et al. **Neurosci Lett** 1985 Apr 9;55(2):141–4

Ibotenic acid lesions of the lateral hypothalamus: comparison with 6–hydroxydopamine–induced sensorimotor deficits. Dunnett SB, et al. **Neuroscience** 1985 Feb;14(2):509–18

Supersensitivity to the anticonvulsant and proconvulsant activity of clonidine following noradrenaline depletion induced by 6–hydroxydopamine. Dalton JC, et al. **Psychopharmacology (Berlin)** 1985;85(3):319–22

Differential effects of dopamine D–1 and D–2 agonists and antagonists in 6–hydroxydopamine–lesioned rats. Arnt J. **Psychopharmacology [Suppl]** 1985;2:60–1

HYDROXYINDOLEACETIC ACID

Effects of jejunoileal bypass on food intake, amino acid levels, and indoleamine metabolism in rats. Herlin PM, et al. **Am J Surg** 1985 Jun; 149(6):739–44

Simultaneous determination of homovanillic acid, 3,4–dihydroxyphenylacetic acid and 5–hydroxyindoleacetic acid in brain tissue, using a double–column procedure. Moroji T, et al. **Arzneimittelforsch** 1985;35(2):478–80

Ontogenetic alterations in the effects of food and/or maternal deprivation on 5–HT, 5–HIAA and 5–HIAA/5–HT ratios. Spear LP, et al. **Brain Res** 1985 Feb;350(1–2):143–57

The influence of testosterone in the brain of the male rat on levels of serotonin (5–HT) and hydroxyindole–acetic acid (5–HIAA). Martinez–Conde E, et al. **Comp Biochem Physiol [C]** 1985; 80(2):411–4

The effects of amiflamine on cerebrospinal fluid amine metabolites in the rhesus monkey. Garrick NA, et al. **Eur J Pharmacol** 1985 Mar 26; 110(1):1–9

Does brain 5-HIAA indicate serotonin release or monoamine oxidase activity? Wolf WA, et al. **Eur J Pharmacol** 1985 Mar 12, 109(3):381-7

[Normal values of dopamine, noradrenaline, adrenaline, and 5-hydroxyindoleacetic acid in pregnancies of different gestational ages] Lerdo de Tejada A, et al. **Ginecol Obstet Mex** 1985 Feb; 53(334):49-52 (Eng. Abstr.) **(Spa)**

HYDROXYTRYPTOPHAN

Antagonism by lisuride and 8-OH-DPAT of 5-HTP-induced prolongation of the performance of male rat sexual behavior. Ahlenius S, et al. **Eur J Pharmacol** 1985 Apr 16;110(3):379-81

L-5-hydroxytryptophan in the treatment of anxiety disorders. Kahn RS, et al. **J Affective Disord** 1985 Mar-Apr;8(2):197-200

Pharmacology in vivo of the phenylindan derivative, Lu 19-005, a new potent inhibitor of dopamine, noradrenaline and 5-hydroxytryptamine uptake in rat brain. Arnt J, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):101-7

HYDROXYZINE

[Atarax] Peutillot JF, et al. **Soins Psychiatr** 1985 Jan;(51):I-II **(Fre)**

HYPOCHONDRIASIS

Modification of disease phobia using a multifaceted exposure program. Tearnan BH, et al. **J Behav Ther Exp Psychiatry** 1985 Mar; 16(1):57-61

IMIPRAMINE

Combined pharmacological and behavioral treatment for agoraphobia. Telch MJ, et al. **Behav Res Ther** 1985;23(3):325-35

Lack of efficacy of estrogen supplementation to imipramine in resistant female depressives. Shapira B, et al. **Biol Psychiatry** 1985 May; 20(5):576-9

Regional distribution and elimination kinetics of imipramine in rat brain. Masada M, et al. **Chem Pharm Bull (Tokyo)** 1984 Nov; 32(11):4678-81

Repeated treatment with imipramine decreased the number of [3H]piflutixol binding sites in the rat striatum. Klimek V, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):131-2

Sex differences in long-term gonadectomized rats: monoamine levels and [3H]nitroimipramine binding in brain nuclei. Renner KJ, et al. **Exp Brain Res** 1985;58(1):198-201

Imipramine metabolism in recurrent depressive episodes. Tollefson G, et al. **J Affective Disord** 1985 Mar-Apr;8(2):183-6

Psychophysiological outcome of behavioral and pharmacological treatments of agoraphobia. Michelson L, et al. **J Consult Clin Psychol** 1985 Apr;53(2):229-36

High- and low-affinity binding components for [3H]imipramine in rat cerebral cortex. Conway PG, et al. **J Neurochem** 1985 Jul; 45(1):206-9

Possible artefacts in imipramine binding assays [letter] Reith ME. **J Neurochem** 1985 Aug;45(2):661-3

5-Methoxytryptoline, a competitive endocoid acting at [3H]imipramine recognition sites in human platelets. Segonzac A, et al. **J Neurochem** 1985 Jul;45(1):249-56

The effect of prolonged treatment with tricyclic antidepressants on the actions of 5-hydroxytryptamine in the hippocampal slice of the rat. Rowan MJ, et al. **Neuropharmacology** 1985 Feb;24(2):131-7

Imipramine in the treatment of panic disorder and its complications. Liebowitz MR. **Psychiatr Clin North Am** 1985 Mar;8(1):37-47

3H-Imipramine binding sites in platelets of hospitalized psychiatric patients. Gentsch C, et al. **Psychiatry Res** 1985 Mar;14(3):177-87

Clomipramine and imipramine in obsessive-compulsive disorder. Volavka J, et al. **Psychiatry Res** 1985 Jan;14(1):85-93

Occurrence of myeloid bodies in rats following two-year administration of imipramine hydrochloride. Spaet RH, et al. **Toxicol Pathol** 1983; 11(1):3-11

[Antenatal effect of imipramine on the ontogeny of the imipramine receptors in the cerebral cortex of rats] Pirogova MV, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):35-8 (Eng. Abstr.) **(Rus)**

ISOCARBOXAZID

Monoamine oxidase inhibitors in the treatment of atypical depression. Zisook S, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):131-7

LACTATES

Plasma levels of glucose, alanine, lactate, and beta-hydroxybutyrate in the unfed spiny dogfish shark (Squalus acanthias) after surgery and following mammalian insulin infusion. deRoos R, et al. **Gen Comp Endocrinol** 1985 Apr;58(1):28-43

Plasma catecholamine and blood lactate cumulation during incremental exhaustive exercise. Lehmann M, et al. **Int J Sports Med** 1985 Apr; 6(2):78-81

Effect of 1,3-butanediol and short chain acids in sow gestation diets on maternal plasma metabolites and fetal energy storage. Spence CA, et al. **J Anim Sci** 1985 May;60(5):1280-7

Lactate transport through the blood-retinal and the blood-brain barrier in rats. Alm A, et al. **Ophthalmic Res** 1985;17(3):181-4

LEARNING

Interfering with taste aversion learning in rats: the role of associative interference. Cannon DS, et al. **Appetite** 1985 Mar;6(1):1-19

Central action of substance P: possible role in reward. Stäubli U, et al. **Behav Neural Biol** 1985 Jan;43(1):100-8

Pre-natal administration of diazepam improves radial maze learning in mice. Benton D, et al. **Comp Biochem Physiol [C]** 1985;80(2):273-5

Methylphenidate in hyperactive children: differential effects of dose on academic, learning, and social behavior. Rapport MD, et al. **J Abnorm Child Psychol** 1985 Jun;13(2):227-43

The role of noradrenaline in tuning and dopamine in switching between signals in the CNS. Oades RD. **Neurosci Biobehav Rev** 1985 Summer; 9(2):261-82

Learning and memory deficits after lesions of the nucleus basalis magnocellularis: reversal by physostigmine. Murray CL, et al. **Neuroscience** 1985 Apr;14(4):1025-32

The effect of chronic vs. acute injection of vasopressin on animal learning and memory. Hamburger-Bar R, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):23-5

LEVODOPA

Effect of L-DOPA on glucose oxidation and incorporation into glycogen in discrete brain regions of the rat. Barash V, et al. **Brain Res** 1985 Jun 3;335(2):347-9

Altered pharmacokinetics of L-dopa metabolism [letter] Melamed E, et al. **Neurology** 1985 Jun;35(6):939-41

LH

Possible site of negative and positive feedback action of oestrogen on gonadotrophin secretion in normal women. Nagahara Y, et al. **Acta Endocrinol (Copenh)** 1985 Apr;108(4):440-4

Effect of dopamine receptor stimulation on the inhibition of LH pulsatility by a met-enkephaline (FK 33-824). del Pozo E, et al. **Acta Neurochir (Wien)** 1985;75(1-4):88-90

Long-term, pulsatile, low dose, subcutaneous luteinizing hormone-releasing hormone administration in men with idiopathic oligozoospermia. Failure of therapeutic and hormonal response. Fauser BC, et al. **Andrologia** 1985 Mar-Apr;17(2):143-9

Control of steroidogenesis in Leydig cells: roles of Ca2+ and lipoxygenase products in LH and LHRH agonist action. Cooke BA, et al. **Ann NY Acad** Sci 1984;438:269-82

Is cAMP the obligatory second messenger in the action of lutropin on Leydig cell steroidogenesis. Themmen AP, et al. **Biochem Biophys Res Commun** 1985 May 16;128(3):1164-72

Dose-dependent inhibition of the preovulatory surges of gonadotropins and prolactin by the antiestrogen CI-628: possible sites of action. De Paolo LV. **Biol Reprod** 1985 May;32(4):745-52

Changes in luteinizing hormone-releasing hormone content of discrete hypothalamic areas associated with spontaneous and induced preovulatory luteinizing hormone surges in the domestic hen. Johnson AL, et al. **Biol Reprod** 1985 May;32(4):813-9

Effect of gonadotropin-releasing hormone antagonists on serum follicle-stimulating hormone and luteinizing hormone under conditions of singular follicle-stimulating hormone secretion. Schwartz NB, et al. **Biol Reprod** 1985 Mar;32(2):391-8

Study of the luteinizing hormone-induced increase of ovarian blood flow during the estrous cycle in the rat. Varga B, et al. **Biol Reprod** 1985 Apr;32(3):480-8

Successful treatment of infertile women with oligomenorrhoea using a combination of an LHRH agonist and exogenous gonadotrophins. Fleming R, et al. **Br J Obstet Gynaecol** 1985 Apr;92(4):369-73

A correlative radioimmunoassay and immunohistochemical study of LHRH-induced LH depletion in the anterior pituitary of male and female neonatal rats in vitro. Watanabe YG, et al. **Cell Tissue Res** 1985; 240(1):95-100

Absence of effect of the peptide PHI-27 on LH release in vitro. Miyake A, et al. **Endocrinol Jpn** 1984 Dec;31(6):821-4

Increased gonadotropin-releasing hormone pulse frequency associated with estrogen-induced luteinizing hormone surges in ovariectomized ewes. Clarke IJ, et al. **Endocrinology** 1985 Jun;116(6):2376-83

Longitudinal study of the surge of gonadotropins induced by exogenous hormones in prepuberal gilts. Fleming MW, et al. **Endocrinology** 1985 May;116(5):1893-8

Relation of circulating estradiol and progesterone to gonadotropin secretion and estrous cyclicity in aging female rats. Lu JK, et al. **Endocrinology** 1985 May;116(5):1953-9

Dynamic characteristics of luteinizing hormone release from perifused sheep anterior pituitary cells stimulated by combined pulsatile and continuous gonadotropin-releasing hormone. McIntosh RP, et al. **Endocrinology** 1985 Jul;117(1):169-79

Neurotransmitters involved in mediating the steroid-dependent suppression of pulsatile luteinizing hormone secretion in anestrous ewes: effects of receptor antagonists. Meyer SL, et al. **Endocrinology** 1985 May;116(5):2054-61

A rise in tonic luteinizing hormone secretion occurs during photoperiod-stimulated sexual maturation of the female ferret. Ryan KD, et al. **Endocrinology** 1985 May;116(5):2013-8

Tunicamycin and neuraminidase effects on luteinizing hormone (LH)-releasing hormone binding and LH release from rat pituitary cells in culture. Schvartz I, et al. **Endocrinology** 1985 Jun;116(6):2341-6

Release of luteinizing hormone and follicle-stimulating hormone from pituitaries of lactating rats by gonadotropin-releasing hormone and high potassium concentration. Smith MS. **Endocrinology** 1985 May;116(5):1826-34

Cytochemical and cytophysiological studies of gonadotropin-releasing hormone (GnRH) target cells in the male rat pituitary: differential effects of androgens and corticosterone on GnRH binding and gonadotropin release. Tibolt RE, et al. **Endocrinology** 1985 Jul;117(1):396-404

FSH and LH response to testosterone and gonadotropin-releasing hormone in aging male rats. Sartin JL, et al. **Exp Aging Res** 1984 Winter;10(4):183-7

Seasonal variations in plasma luteinizing hormone and testosterone levels in the European badger Meles meles L. Audy MC, et al. **Gen Comp Endocrinol** 1985 Mar;57(3):445-53

Seasonal variation in pituitary responsiveness to luteinizing hormone-releasing hormone of mallards and canvasbacks. Bluhm CK. **Gen Comp Endocrinol** 1985 Jun;58(3):491-7

Changes in hormone levels in relation to breeding behavior in male bullfrogs (Rana catesbeiana) at the individual and population levels. Mendonça MT, et al. **Gen Comp Endocrinol** 1985 May;58(2):270-9

Short-term changes in plasma levels of hormones during establishment and defense of a breeding territory in male song sparrows, Melospiza melodia. Wingfield JC. **Horm Behav** 1985 Jun;19(2):174-87

Effects of short-term exposure to catecholestrogens on serum concentrations of gonadotrophins and metabolism of catecholestrogens in ovariectomized rats. Ball P, et al. **Horm Metab Res** 1985 Apr;17(4):184-8

Effect of castration and steroid treatment on the release of gonadotropins by the rat pituitary-hypothalamus complex in vitro. Gill MK, et al. **Horm Metab Res** 1985 Mar;17(3):141-6

Prolonged suppression of plasma LH levels in male rats after a single injection of an LH-RH agonist in poly(DL-lactide-co-glycolide) microcapsules. Asch RH, et al. **J Androl** 1985 Mar-Apr;6(2):83-8

Hormonal responses to short term fasting in postmenopausal women. Beitins IZ, et al. **J Clin Endocrinol Metab** 1985 Jun;60(6):1120-6

Radioimmunoassay of luteinizing hormone in the baboon (Papio hamadryas). Khan SA, et al. **J Med Primatol** 1985;14(3):143-57

GnRH pulse frequency determines LH pulse amplitude by altering the amount of releasable LH in the pituitary glands of ewes. Clarke IJ, et al. **J Reprod Fertil** 1985 Mar;73(2):425-31

Changes in pulsatile LH secretion and the positive and negative feedback actions of oestradiol after administration of a GnRH agonist in the ovariectomized ewe. Fitzgerald BP, et al. **J Reprod Fertil** 1985 Mar;73(2):433-40

Changes in pituitary and ovarian LHRH receptors after active immunization of female rats against LH or LHRH. Popkin RM, et al. **J Reprod Fertil** 1985 Mar;73(2):491-6

Increased gonadotrophin releasing hormone receptors on pituitary gonadotrophs: effect on subsequent LH secretion. Young LS, et al. **Mol Cell Endocrinol** 1985 Jun;41(1):69-78

Diacylglycerols and protein kinase C. Potential amplifying mechanism for Ca2+-mediated gonadotropin-releasing hormone-stimulated luteinizing hormone release. Harris CE, et al. **Mol Pharmacol** 1985 May;27(5):532-6

Pineal melatonin mediates photoperiodic control of pulsatile luteinizing hormone secretion in the ewe. Bittman EL, et al. **Neuroendocrinology** 1985 May;40(5):409-18

Differential suppression of follicle-stimulating hormone and luteinizing hormone secretion in vivo by a gonadotropin-releasing hormone antagonist. Grady RR, et al. **Neuroendocrinology** 1985 Mar;40(3):246-52

Medial preoptic area involvement in norepinephrine-induced suppression of pulsatile luteinizing hormone release in ovariectomized rats. Leipheimer RE, et al. **Neuroendocrinology** 1985 Apr;40(4):345-51

Clinical value of biological activity of serum luteinizing hormone in patients with ovulatory failure. Kuramoto T. **Nippon Sanka Fujinka Gakkai Zasshi** 1985 May;37(5):793-8

Leukotriene C4 as a mediator of luteinizing hormone release from rat anterior pituitary cells. Hulting AL, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(11):3834-8

[Activity of clobazam on plasma prolactin and gonadotropins after administration of sulpiride in the male rat] Valli M, et al. **Ann Endocrinol (Paris)** 1984;45(6):409-11 (Eng. Abstr.) **(Fre)**

[The effects of bromocriptine on anovulatory patients with high LH and euprolactinemia] Mori H, et al. **Nippon Naibunpi Gakkai Zasshi** 1985 Jan 20;61(1):48-55 (Eng. Abstr.) **(Jpn)**

[Biological and immunological characterization of human luteinizing hormone in plasma discharged by LH-RH infusion in normal adult women] Yano M. **Nippon Sanka Fujinka Gakkai Zasshi** 1985 May;37(5):703-12 (Eng. Abstr.) **(Jpn)**

LH-FSH RELEASING HORMONE

Treatment of hypothalamic infertility with pulsatile GN-RH administration. Turla R, et al. **Acta Eur Fertil** 1984 Nov-Dec;15(6):445-8

Successful treatment of anovulatory sterility by use of pulsatile GN-RH application. Wiegand M, et al. **Acta Eur Fertil** 1984 Nov-Dec;15(6):467-8

Success and relapse rate after treatment of cryptorchidism with intranasal LHRH. Schwarz HP, et al. **Acta Paediatr Scand** 1985 Mar;74(2):274-80

Comparison between the steroidogenic responses after pulsatile and continuous administration of gonadotrophin releasing hormone to superfused rat follicles. Hedin L. **Acta Physiol Scand** 1985 Jun;124(2):269-76

Characteristics and bioefficacy of monoclonal antigonadotropin releasing hormone antibody. Gupta SK, et al. **Am J Reprod Immunol Microbiol** 1985 Mar;7(3):104-8

Long-term, pulsatile, low dose, subcutaneous luteinizing hormone-releasing hormone administration in men with idiopathic oligozoospermia. Failure of therapeutic and hormonal response. Fauser BC, et al. **Andrologia** 1985 Mar-Apr;17(2):143-9

Control of steroidogenesis in Leydig cells: roles of Ca2+ and lipoxygenase products in LH and LHRH agonist action. Cooke BA, et al. **Ann NY Acad Sci** 1984;438:269-82

Studies on the identification of a LHRH-like peptide in the rat testis. Hedger MP, et al. **Ann NY Acad Sci** 1984;438:371-81

Molecular dynamics and minimum energy conformations of GnRH and analogs. A methodology for computer-aided drug design. Struthers RS, et al. **Ann NY Acad Sci** 1985;439:81-96

GnRH-like factors in the rat testis and human seminal plasma. Swerdloff RS, et al. **Ann NY Acad Sci** 1984;438:382-9

Luteinising hormone releasing hormone for incomplete descent of the testis. Klidjian AM, et al. **Arch Dis Child** 1985 Jun;60(6):568-71

Discrete hypothalamic distribution of luteinizing hormone-releasing hormone (LHRH) content and of LHRH-degrading activity in laying and nonlaying hens. Advis JP, et al. **Biol Reprod** 1985 May;32(4):820-7

Gonadotropin-releasing hormone stimulation of pituitary gonadotrope cells produces an increase in intracellular calcium. Clapper DL, et al. **Biol Reprod** 1985 Mar;32(2):269-78

Changes in luteinizing hormone-releasing hormone content of discrete hypothalamic areas associated with spontaneous and induced preovulatory luteinizing hormone surges in the domestic hen. Johnson AL, et al. **Biol Reprod** 1985 May;32(4):813-9

Effect of gonadotropin-releasing hormone antagonists on serum follicle-stimulating hormone and luteinizing hormone under conditions of singular follicle-stimulating hormone secretion. Schwartz NB, et al. **Biol Reprod** 1985 Mar;32(2):391-8

D-Ala6-des-Gly10-gonadotropin-releasing hormone ethylamide: absence of binding sites and lack of a direct effect in rabbit corpora lutea. Thorson JA, et al. **Biol Reprod** 1985 Mar;32(2):226-31

Biochemical transmethylation of lipids and neuropeptidergic stimulation of pituitary hormone secretion. Prasad C, et al. **Brain Res** 1985 May 13;334(1):41-6

Effects of prostaglandins and luteinizing hormone-releasing hormone on phosphatidic acid-phosphatidylinositol labeling in rat granulosa cells. Minegishi T, et al. **Can J Physiol Pharmacol** 1985 Apr;63(4):320-4

A correlative radioimmunoassay and immunohistochemical study of LHRH-induced LH depletion in the anterior pituitary of male and female neonatal rats in vitro. Watanabe YG, et al. **Cell Tissue Res** 1985;240(1):95-100

The effects of the GnRH agonist, [(imBzl)-D-His6, Pro9-NEt]-GnRH, on the response to stress in rats. Gibson MJ, et al. **Contraception** 1985 Jan;31(1):91-9

Distribution of luteinizing hormone-releasing hormone (LHRH) content and total LHRH-degrading activity (LHRH-DA) in the hypothalamus of the ewe. Advis JP, et al. **Endocrinology** 1985 Jun;116(6):2410-8

A role for extracellular copper in modulating prostaglandin E2 (PGE2) action: facilitation of PGE2 stimulation of the release of gonadotropin-releasing hormone (LHRH) from median eminence explants. Barnea A, et al. **Endocrinology** 1985 Jul;117(1):415-7

D-Trp-6-luteinizing hormone-releasing hormone inhibits hyperprolactinemia in female rats. Debeljuk L, et al. **Endocrinology** 1985 Jun;116(6):2227-31

Prostaglandin E2-induced luteinizing hormone-releasing hormone release involves mobilization of intracellular Ca+2. Ojeda SR, et al. **Endocrinology** 1985 May;116(5):1763-70

Tunicamycin and neuraminidase effects on luteinizing hormone

(LH)-releasing hormone binding and LH release from rat pituitary cells in culture. Schvartz I, et al. **Endocrinology** 1985 Jun;116(6):2341-6

Cytochemical and cytophysiological studies of gonadotropin-releasing hormone (GnRH) target cells in the male rat pituitary: differential effects of androgens and corticosterone on GnRH binding and gonadotropin release. Tibolt RE, et al. **Endocrinology** 1985 Jul;117(1):396-404

Exogenous progesterone for luteal support following gonadotropin-releasing hormone ovulation induction: case report. Berger NG, et al. **Fertil Steril** 1985 Jul;44(1):133-5

Does constant infusion of gonadotropin-releasing hormone agonist lead to greater suppression of gonadal function in man than its intermittent administration? Bhasin S, et al. **Fertil Steril** 1985 Jul;44(1):96-101

Immunoreactive luteinizing hormone-releasing hormone in the seminal plasma and human semen parameters. Izumi S, et al. **Fertil Steril** 1985 Apr;43(4):617-20

Effect on corpus luteum function of luteal phase administration of a potent gonadotropin-releasing hormone analog (nafarelin). Schriock ED, et al. **Fertil Steril** 1985 Jun;43(6):844-50

Seasonal variation in pituitary responsiveness to luteinizing hormone-releasing hormone of mallards and canvasbacks. Bluhm CK. **Gen Comp Endocrinol** 1985 Jun;58(3):491-7

Pimozide modulates the luteinizing hormone-releasing hormone effect on gonadotrophin release in the African catfish, Clarias lazera. de Leeuw R, et al. **Gen Comp Endocrinol** 1985 Apr;58(1):120-7

Structure-activity relationships of mammalian, chicken, and salmon gonadotropin releasing hormones in vivo in goldfish. Peter RE, et al. **Gen Comp Endocrinol** 1985 May;58(2):231-42

Seasonal effects of pimozide and des Gly10 [D-Ala6] LH-RH ethylamide on gonadotrophin secretion in goldfish. Sokolowska M, et al. **Gen Comp Endocrinol** 1985 Mar;57(3):472-9

Seasonal changes in luteinizing hormone-releasing hormone concentrations in microdissected brain regions of male rough-skinned newts (Taricha granulosa). Zoeller RT, et al. **Gen Comp Endocrinol** 1985 May;58(2):222-30

Effect of gonadotropin releasing hormone on ventral prostate of rat. Raju VS, et al. **Horm Metab Res** 1985 May;17(5):241-3

Detection of prolactin and LH releasing activity in mid-term human fetal cerebrospinal fluid. Gilmore DP, et al. **Indian J Exp Biol** 1984 Nov;22(11):586-8

Immunological castration by a totally synthetic vaccine: modification of biological properties of LH-RH after conjugation to adjuvant-active muramyl peptide. Carelli C, et al. **Int J Immunopharmacol** 1985;7(2):215-24

Prolonged suppression of plasma LH levels in male rats after a single injection of an LH-RH agonist in poly(DL-lactide-co-glycolide) microcapsules. Asch RH, et al. **J Androl** 1985 Mar-Apr;6(2):83-8

The priming effect of LH-releasing hormone: effects of cold and involvement of new protein synthesis. Curtis A, et al. **J Endocrinol** 1985 May;105(2):163-8

Pituitary and gonadal response to exogenous LH-releasing hormone in the male domestic cat. Goodrowe KL, et al. **J Endocrinol** 1985 May;105(2):175-81

Immunocytochemistry of luteinizing hormone-releasing hormone during spontaneous and thyroxine-induced metamorphosis of bullfrogs. Whalen R, et al. **J Exp Zool** 1985 Apr;234(1):131-44

Improved antagonists of luteinizing hormone-releasing hormone modified in position 7. Hocart SJ, et al. **J Med Chem** 1985 Jul;28(7):967-70

Changes in pituitary and ovarian LHRH receptors after active immunization of female rats against LH or LHRH. Popkin RM, et al. **J Reprod Fertil** 1985 Mar;73(2):491-6

Induction of oestrus and ovulation by means of prostaglandin and gonadoliberin (GnRH) treatment in an old mare barren for two breeding seasons. Penzhorn BL, et al. **J S Afr Vet Assoc** 1985 Mar;56(1):53-4

Changes in plasma steroid levels after single administration of hCG or LHRH agonist analogue in dog and rat. Tremblay Y, et al. **J Steroid Biochem** 1985 Mar;22(3):315-20

Progesterone-induced LHRH release in vitro is an estrogen--as well as Ca++- and calmodulin-dependent secretory process. Drouva SV, et al. **Neuroendocrinology** 1985 Apr;40(4):325-31

Lipoxygenase products of arachidonic acid stimulate LHRH release from rat median eminence. Gerozissis K, et al. **Neuroendocrinology** 1985 Mar;40(3):272-6

Responsiveness of immature versus adult male rat hypothalami to dibutyryl cyclic AMP- and forskolin-induced LHRH release in vitro. Hartter DE, et al. **Neuroendocrinology** 1985 Jun;40(6):476-82

Glutamic acid decarboxylase-containing axons synapse on LHRH neurons in the rat medial preoptic area. Leranth C, et al. **Neuroendocrinology** 1985 Jun;40(6):536-9

Effects of progesterone on hypothalamic and plasma LHRH. Peduto JC, et al. **Neuroendocrinology** 1985 Mar;40(3):238-45

Apparent lack of involvement of cAMP as a mediator of LHRH stimulation of nuclear estrogen receptor activity in the rat anterior pituitary. Singh P, et al. **Neuroendocrinology** 1985 May;40(5):430-7

Shifts in gonadotropin storage in cultured gonadotropes following GnRH stimulation, in vitro. Childs GV. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):103-7

A new antiserum with conformational specificity for LHRH: usefulness for radioimmunoassay and immunocytochemistry. Ellinwood WE, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):45-52

D-Tryptophan-6 analog of luteinizing hormone-releasing hormone as a protective agent against testicular damage caused by cyclophosphamide in baboons. Lewis RW, et al. **Proc Natl Acad Sci USA** 1985 May;82(9):2975-9

Possible negative ultra-short loop feedback of luteinizing hormone releasing hormone (LHRH) in the ovariectomized rat. Bedran de Castro JC, et al. **Proc Soc Exp Biol Med** 1985 May;179(1):132-5

Induction of the self-priming effect of luteinizing hormone releasing hormone during the sexual maturation of the male rat. Nazian SJ. **Proc Soc Exp Biol Med** 1985 Jul;179(3):348-51

Luteinizing-hormone-releasing hormone modifies retention of passive and active avoidance responses in rats. Mora S, et al. **Psychopharmacology (Berlin)** 1985;85(3):315-8

[LHRH stimulates the secretion of an 87 K protein by cultured gonadotrophic cells] Hubert JF, et al. **C R Acad Sci [III]** 1985;300(16):613-6 (Eng. Abstr.) **(Fre)**

[Pulsatile treatment with LH-RH using a portable pump: a new modality for inducing ovulation and treating sterility] Thomas D, et al. **Rev Med Brux** 1985 May;6(5):325-33 (Eng. Abstr.) **(Fre)**

[Treatment of cryptorchism with LHRH nasal spray] Borkenstein M, et al. **Wien Klin Wochenschr** 1985 Apr 26;97(9):414-6 (Eng. Abstr.) **(Ger)**

[Effects of iontophoretically-applied LHRH, TRH, estrogen and clomiphene on thermo-sensitive neurons in the rat hypothalamus] Inagaki K, et al. **Nippon Sanka Fujinka Gakkai Zasshi** 1985 Apr;37(4):611-8 (Eng. Abstr.) **(Jpn)**

[Biological and immunological characterization of human luteinizing hormone in plasma discharged by LH-RH infusion in normal adult women] Yano M. **Nippon Sanka Fujinka Gakkai Zasshi** 1985 May;37(5):703-12 (Eng. Abstr.) **(Jpn)**

[Immunohistochemical research on the development of the LHRH system in the development of the rat] Ugriumov MV, et al. **Dokl Akad Nauk SSSR** 1985;280(6):1425-7 **(Rus)**

[Synthetic tripeptide miniluliberin and its biological activity] Babichev VN, et al. **Probl Endokrinol (Mosk)** 1985 Mar-Apr;31(2):47-9 (Eng. Abstr.) **(Rus)**

LIPOTROPIN

Determination of beta-endorphin and beta-lipotropin in human cerebrospinal fluid. Laatikainen TJ, et al. **Clin Chim Acta** 1985 Feb 15;145(3):325-9

[Immunoreactive beta-lipotropin and endorphins are secreted by the isolated alimentary complex of rats] Titov MI, et al. **Dokl Akad Nauk SSSR** 1985;281(2):497-9 **(Rus)**

LITHIUM

Renal function in 153 manic-depressive patients treated with lithium for more than five years. Løkkegaard H, et al. **Acta Psychiatr Scand** 1985 Apr;71(4):347-55

Plasma lithium level and interepisode functioning in bipolar disorder. Goodnick PJ, et al. **Am J Psychiatry** 1985 Jun;142(6):761-2

Lithium-selective polymeric membrane electrodes based on dodecylmethyl-14-crown-4. Kitazawa S, et al. **Analyst** 1985 Mar;110(3):295-9

A novel technique for assessing the sources of dietary sodium. Sanchez-Castillo CP, et al. **Ann Clin Res** 1984;16 Suppl 43:44-8

Can lithium carbonate prolong the antidepressant effect of sleep deprivation? [letter] Baxter LR Jr. **Arch Gen Psychiatry** 1985 Jun;42(6):635

Decreased myeloperoxidase activity of mice polymorphonuclear leukocytes by lithium carbonate treatment. Gómez-Estrada H, et al. **Arch Invest Med (Mex)** 1984 Oct-Dec;15(4):287-91 **(Eng, Spa)**

Automated determinations of K+ and Li+ with a microprocessor-controlled flame photometer [letter] Soltero RA. **Clin Chem** 1985 Jun;31(6):1094

Consensus development summaries. Mood disorders: pharmacologic prevention of recurrences. National Institutes of Health. **Conn Med** 1985 Mar;49(3):157-63

The effect of sulindac on lithium therapy. Furnell MM, et al. **Drug Intell Clin Pharm** 1985 May;19(5):374-6

The effect of lithium carbonate administration on growth in the domestic fowl. Lozanoff S, et al. **Growth** 1985 Spring;49(1):91-104

Lithium-stimulated recovery of granulopoiesis after sublethal irradiation is not mediated via increased levels of colony stimulating factor (CSF). Gallicchio VS, et al. **Int J Radiat Biol** 1985 May;47(5):581-90

The influence of mania and depression on the pharmacokinetics of lithium. A longitudinal single-case study. Kukopoulos A, et al. **J Affective Disord** 1985 Mar-Apr;8(2):159-66

Mania. Diagnosis, state measurement and prediction of treatment response. Secunda SK, et al. **J Affective Disord** 1985 Mar-Apr;8(2):113-21

Severe prolonged catatonia with associated flushing reaction responsive

to lithium carbonate. Pheterson AD, et al. **J Am Acad Child Psychiatry** 1985 Mar;24(2):235-7
Brain glycine levels following lithium toxicity: case report. Stanley M, et al. **J Clin Psychiatry** 1985 Jun;46(6):239
Treatment-resistant catatonic stupor and combined lithium-neuroleptic therapy: a case report. Climo LH. **J Clin Psychopharmacol** 1985 Jun; 5(3):166-70
A pharmacokinetic approach to the study of cell membrane lithium transport in vivo. Mallinger AG, et al. **J Clin Psychopharmacol** 1985 Apr;5(2):78-82
Lithium therapy for mania and depression. Murray JB. **J Gen Psychol** 1985 Jan;112(1):5-33
Na+ (Li+)-proline cotransport in Escherichia coli. Chen CC, et al. **J Membr Biol** 1985;84(2):157-64
The effect of acute lithium administration on brain monoamine synthesis and the precursor amino acids tyrosine and tryptophan in brain and plasma in rats. Berggren U. **J Neural Transm** 1985;61(3-4):175-81
Denervation supersensitivity of the rat pineal to norepinephrine-stimulated [3H]inositide turnover revealed by lithium and a convenient procedure. Zatz M. **J Neurochem** 1985 Jul; 45(1):95-100
Lithium-induced improvement of myotonia: relevance of prostaglandin E1 blockade by lithium [letter] Backon J. **J Neurol Neurosurg Psychiatry** 1985 Jun;48(6):606-7
Familial differences in lithium responsive versus lithium nonresponsive psychoses. Sautter F, et al. **J Psychiatr Res** 1985;19(1):1-8
Poor response when laboratory recommended range for serum lithium is changed [letter] Masterton G, et al. **Lancet** 1985 Apr 27; 1(8435):981
Mood disorders: pharmacologic prevention of recurrences. National Institutes of Health Consensus Development Conference Statement. **Nat Inst Health Consensus Dev Conf Consensus Statement** 1984; 5(4):8 p.
Effects of acute oral administration of lithium compounds on multiple schedule performance in rats. Chrislip DW, et al. **Neurobehav Toxicol Teratol** 1985 Jan-Feb;7(1):39-42
Effects of lithium in vitro on noradrenaline-induced cyclic AMP accumulation in rat cortical slices after reserpine-induced supersensitivity. Newman ME, et al. **Neuropharmacology** 1985 Apr; 24(4):353-5
Comparison of the changes in central catecholamine systems following short- and long-term lithium treatment and the consequences of lithium withdrawal. Ahluwalia P, et al. **Neuropsychobiology** 1984; 12(4):217-23
Mechanisms of the central action of lithium. Sinitskii VN, et al. **Neurosci Behav Physiol** 1985 Jan-Feb;15(1):81-8
Compliance with outpatient lithium therapy. Connelly CE. **Perspect Psychiatr Care** 1984 Apr-Jun;22(2):44-50
Lithium effects on position learning with exploratory and aversive goal-box conditions. Hines G. **Pharmacol Biochem Behav** 1985 May; 22(5):695-8
Effects of chronic LiCl and RbCl on muricide induced by midbrain raphe lesions in rats. Yamamoto T, et al. **Pharmacol Biochem Behav** 1985 Apr; 22(4):559-63
How does the patient prefer his lithium treatment? Vestergaard P. **Pharmacopsychiatry** 1985 May;18(3):223-4
Lithiated compounds of biological and oncological interest. Allen EB, et al. **Prog Clin Biol Res** 1985;172B:311-9
Interdependency of lithium ratio, plasma lithium level and clinical state in patients with affective disorders. Elizur A, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(2):167-72
Combined lithium and valproate treatment and subsequent withdrawal: serotonergic mechanism of their interaction in discrete brain regions. Shukla GS. **Prog Neuropsychopharmacol Biol Psychiatry** 1985; 9(2):153-6
Influence of GABA mimetics and lithium on biochemical manifestations of striatal dopamine target cell hypersensitivity. Scatton B, et al. **Psychopharmacology [Suppl]** 1985;2:39-45
Bipolar disorder and social work practice. Sands RG. **Soc Work Health Care** 1985 Spring;10(3):91-105
[Compartmental analysis of 6Li/7Li isotope exchange in equilibrium conditions in mouse plasma] Heurteaux C, et al. **C R Acad Sci [III]** 1985;300(14):529-34 (Eng. Abstr.) **(Fre)**
[Indications and monitoring of lithium treatment] Singer L, et al. **Rev Prat** 1985 May 11;35(27):1657-8, 1661-4 (Eng. Abstr.) **(Fre)**
[Effect of lithium on the proliferation of fibroblasts and tumor cell lines in vitro] Bruchelt G, et al. **Klin Padiatr** 1985 May-Jun; 197(3):249-52 (Eng. Abstr.) **(Ger)**
[Effect of lithium carbonate on the leukocyte count after exposure to ionizing radiation. 2. Influence of lithium carbonate on the leukocyte ratio in peripheral blood] Rose H, et al. **Radiobiol Radiother (Berl)** 1985; 26(1):103-7 (Eng. Abstr.) **(Ger)**
[Effect of lithium carbonate on the leukocyte count after exposure to ionizing radiation. 3. Influence of lithium carbonate on the leukocyte count in peripheral blood following fractionated caudal half-body irradiation] Rose H, et al. **Radiobiol Radiother (Berl)** 1985; 26(1):109-11 (Eng. Abstr.) **(Ger)**
[A case of simultaneous treatment of the manic syndrome and granulocytopenia with lithium salts] Greń K, et al. **Psychiatr Pol** 1984 May-Jun;18(3):285-8 **(Pol)**
[Effect of preventive administration of lithium carbonate on serum concentrations of various pituitary and peripheral hormones in patients with endogenous depression] Horodnicki JM, et al. **Psychiatr Pol** 1984 Jul-Aug;18(4):319-25 (Eng. Abstr.) **(Pol)**
[Lithium salts in the treatment of schizoaffective psychosis] Kopel A. **Psychiatr Pol** 1984 May-Jun;18(3):279-83 **(Pol)**

LORAZEPAM

Aminophylline is an antagonist of lorazepam. Wangler MA, et al. **Anesth Analg** 1985 Aug;64(8):834-6
A comparison of the effects of lorazepam with those of propranolol on experimentally-induced anxiety and performance. File SE, et al. **Br J Clin Pharmacol** 1985 Apr;19(4):445-51
Clonidine in benzodiazepine withdrawal [letter] Keshavan MS, et al. **Lancet** 1985 Jun 8;1(8441):1325-6
Information processing and benzodiazepines. Kleindienst-Vanderbeke G. **Neuropsychobiology** 1984;12(4):238-43
[Intravenous sedation before endoscopic interventions. Comparative study of lormetazepam and diazepam in oil] Tolksdorf W, et al. **Fortschr Med** 1985 Mar 7;103(9):249-52 (Eng. Abstr.) **(Ger)**

MANIC DISORDER

A controlled clinical trial of L-tryptophan in acute mania. Chouinard G, et al. **Biol Psychiatry** 1985 May;20(5):546-57
The influence of mania and depression on the pharmacokinetics of lithium. A longitudinal single-case study. Kukopoulos A, et al. **J Affective Disord** 1985 Mar-Apr;8(2):159-66
Mania. Diagnosis, state measurement and prediction of treatment response. Secunda SK, et al. **J Affective Disord** 1985 Mar-Apr;8(2):113-21
Comparison of antimanic efficacy of clonidine and verapamil. Giannini AJ, et al. **J Clin Pharmacol** 1985 May-Jun;25(4):307-8

MATERNAL BEHAVIOR

Prenatal stress impairs maternal behavior in a conflict situation and reduces hippocampal benzodiazepine receptors. Fride E, et al. **Life Sci** 1985 Jun 3;36(22):2103-9

MEMORY

Catecholamine microfluorometry of nigral perikarya and tyrosine hydroxylase assay in some telencephalic structures of rats exposed to different behavioral situations. Divac I, et al. **Acta Neurobiol Exp (Warsz)** 1984;44(6):262-72
Mediation of storage and retrieval with two drugs that selectively modulate serotonergic neurotransmission. Altman HJ. **Ann NY Acad Sci** 1985;444:496-8
Lesions in nucleus basalis magnocellularis and medial septal area of rats produce similar memory impairments in appetitive and non-appetitive behavioral tasks. Hepler D, et al. **Ann NY Acad Sci** 1985;444:518-9
Peripheral and central adrenergic influences on brain systems involved in the modulation of memory storage. McGaugh JL. **Ann NY Acad Sci** 1985;444:150-61
Arginine vasopressin inoculates against age-related changes in temporal memory. Meck WH, et al. **Ann NY Acad Sci** 1985;444:453-6
Noradrenergic modulation of selective attention: its role in memory retrieval. Sara SJ. **Ann NY Acad Sci** 1985;444:178-93
AF64A produces long-term cognitive impairments following infusion into the lateral cerebral ventricles or the dorsal hippocampus: involvement of hippocampal cholinergic processes in learning and memory. Walsh TJ, et al. **Ann NY Acad Sci** 1985;444:538-40
Depletion of adrenal catecholamines alters the amnestic effect of amygdala stimulation. Bennett C, et al. **Behav Brain Res** 1985 Apr;15(2):83-91
Peripheral epinephrine modulates the effects of post-training amygdala stimulation on memory. Liang KC, et al. **Behav Brain Res** 1985 Apr; 15(2):93-100
Physostigmine reverses memory deficits produced by pretraining electrical stimulation of the dorsal hippocampus in mice. Micheau J, et al. **Behav Brain Res** 1985 Apr;15(2):75-81
Effects of tifluadom on passive avoidance behaviour in DBA/2 mice. Pavone F, et al. **Behav Brain Res** 1985 May;15(3):177-81
Brain catecholamines and memory modulation: effects of footshock, amygdala implantation, and stimulation. Welsh KA, et al. **Behav Neural Biol** 1985 Mar;43(2):119-31
Increased sensitivity of the elderly to the central depressant effects of diazepam. Pomara N, et al. **J Clin Psychiatry** 1985 May;46(5):185-7
Interaction of choline and scopolamine in human memory. Mohs RC, et al. **Life Sci** 1985 Jul 15;37(2):193-7
Effects of dietary choline on memory and brain chemistry in aged mice. Mizumori SJ, et al. **Neurobiol Aging** 1985 Spring;6(1):51-6
Learning and memory deficits after lesions of the nucleus basalis

magnocellularis: reversal by physostigmine. Murray CL, et al. **Neuroscience** 1985 Apr;14(4):1025–32

The effect of chronic vs. acute injection of vasopressin on animal learning and memory. Hamburger-Bar R, et al. **Peptides (Fayetteville)** 1985 Jan–Feb;6(1):23–5

Manipulations of 5-HT activity and memory in the rat. Lalonde R, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):377–82

The effects of intravenous diazepam and hyoscine upon human memory. Frith CD, et al. **Q J Exp Psychol [A]** 1984 Feb;36(1):133–44

MEMORY, SHORT-TERM

Effects of zopiclone and benzodiazepine hypnotics on search in short-term memory. Subhan Z, et al. **Neuropsychobiology** 1984;12(4):244–8

MENTAL DISORDERS

1st Czechoslovak Conference on Biological Psychiatry. Karlovy Vary (Karlsbad), September 1983. Abstracts. **Act Nerv Super (Praha)** 1985 Mar;27(1):60–72

26th annual psychopharmacological meeting. Jeseník Spa, January 1984. Proceedings, 2nd part. Abstracts. **Act Nerv Super (Praha)** 1985 Mar; 27(1):26–72

The pharmacokinetization of psychiatry [editorial] Greenblatt DJ. **J Clin Pharmacol** 1985 May–Jun;25(4):239–40

Treatment characteristics of psychiatric programs that correlate with patient community adjustment. Collins JF, et al. **J Clin Psychol** 1985 May;41(3):299–308

Compliance issues in outpatient treatment. Kane JM. **J Clin Psychopharmacol** 1985 Jun;5(3 Suppl):22S–27S

Behavioral rehabilitation for chronic mental patients. Liberman RP, et al. **J Clin Psychopharmacol** 1985 Jun;5(3 Suppl):8S–14S

The young adult chronic patient: population overview. Pepper B. **J Clin Psychopharmacol** 1985 Jun;5(3 Suppl):3S–7S

MAOIs and drug interactions––a proposal for a clearinghouse. Shader RI, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):A17

The chronic patient: issues and concerns. Shader RI, et al. **J Clin Psychopharmacol** 1985 Jun;5(3 Suppl):1S–2S

Focal neuroleptization: an approach to optimal dosing for initial and continuing therapy. Tupin JP. **J Clin Psychopharmacol** 1985 Jun; 5(3 Suppl):15S–21S

The clinical significance of halopemide, a dopamine-blocker related to the butyrophenones. De Cuyper H, et al. **Neuropsychobiology** 1984; 12(4):211–6

Effects of psychotropic drugs on discrimination conditioning in olfactory bulbectomized rats. Gomita Y, et al. **Pharmacol Biochem Behav** 1985 May;22(5):717–22

Proceedings of the congress of the AGNP. Nuremberg, 1983. Abstracts. **Pharmacopsychiatry** 1985 Jan;18(1):1–177

8th congress of the Polish Pharmacological Society. Symposium II: Pharmacological implications for animal models of mental disorders. **Pol J Pharmacol Pharm** 1984 Sep–Oct;36(5):493–569

3H-Imipramine binding sites in platelets of hospitalized psychiatric patients. Gentsch C, et al. **Psychiatry Res** 1985 Mar;14(3):177–87

Thorazine injected; pt. dies: criminal charges. Case in point: people v. Nygren (696 P. 2d 270––CO). Tammelleo AD. **Regan Rep Nurs Law** 1985 May;25(12):2

[Prescribing psychoactive drugs for children] Bläker F, et al. **Monatsschr Kinderheilkd** 1985 May;133(5):307–9 **(Ger)**

MEPROBAMATE

Meprobamate overdosage. Dennison J, et al. **Hum Toxicol** 1985 Mar; 4(2):215–7

[Responsibility of meprobamate in bone marrow aplasia (letter)] Evreux JC, et al. **Presse Med** 1985 Apr 6;14(14):793 **(Fre)**

METHOTRIMEPRAZINE

[Nozinan] Scottez B, et al. **Soins Psychiatr** 1985 Mar;(53):I–II **(Fre)**

[Clinico-humoral manifestations secondary to treatment with injectable Tisercin] Gheorghe M, et al. **Rev Med Interna [Neurol Psihiatr]** 1985 Jan–Mar;30(1):71–2 **(Rum)**

METHYLPHENIDATE

Place preference conditioning with methylphenidate and nomifensine. Martin-Iverson MT, et al. **Brain Res** 1985 Apr 15;332(1):59–67

Evaluating drug effectiveness in an office setting for children with attention deficit disorders. Ottinger DR, et al. **Clin Pediatr (Phila)** 1985 May;24(5):245–51

Methylphenidate in hyperactive children: differential effects of dose on academic, learning, and social behavior. Rapport MD, et al. **J Abnorm Child Psychol** 1985 Jun;13(2):227–43

Combined MAOI, TCA, and direct stimulant therapy of treatment-resistant depression. Feighner JP, et al. **J Clin Psychiatry** 1985 Jun;46(6):206–9

Pharmacological treatment of attention deficit disorder, residual type (ADD,RT, 'minimal brain dysfunction,' 'hyperactivity') in adults. Wender PH, et al. **Psychopharmacol Bull** 1985;21(2):222–31

Methylphenidate: rate dependent drug effects in hyperactive boys. Weber K. **Psychopharmacology (Berlin)** 1985;85(2):231–5

METHYSERGIDE

Control of suckling and feeding by methysergide in weaning albino rats: a determination of Y-maze preferences. Stoloff ML, et al. **Dev Psychobiol** 1985 May;18(3):273–85

Effects of quipazine and methysergide on play in juvenile rats. Normansell L, et al. **Pharmacol Biochem Behav** 1985 May;22(5):885–7

MOTIVATION

The role of noradrenaline in tuning and dopamine in switching between signals in the CNS. Oades RD. **Neurosci Biobehav Rev** 1985 Summer; 9(2):261–82

Glutamine-induced alterations in the content of brain amino acid neurotransmitters in rats with different alcohol motivation. Ostrovsky SYu. **Subst Alcohol Actions Misuse** 1984;5(5):247–53

MOTOR ACTIVITY

Activity measures in anorexia nervosa. Falk JR, et al. **Arch Gen Psychiatry** 1985 Aug;42(8):811–4

The effect of methyl parathion on susceptibility of bobwhite quail (Colinus virginianus) to domestic cat predation. Galindo JC, et al. **Behav Neural Biol** 1985 Jan;43(1):21–36

SCH 23390 may alter dopamine-mediated motor behaviour via striatal D-1 receptors. Boyce S, et al. **Biochem Pharmacol** 1985 May 15; 34(10):1665–9

Association of the mesencephalic locomotor region with locomotor activity induced by injections of amphetamine into the nucleus accumbens. Brudzyński SM, et al. **Brain Res** 1985 May 13; 334(1):77–84

Quantification of lesion-induced dopaminergic supersensitivity using the rotational model in the mouse. Mandel RJ, et al. **Brain Res** 1985 Mar 25;330(2):358–63

Neonatal 6-hydroxydopamine lesion of spinal norepinephrine terminals fails to affect the ontogeny of swimming behavior. Ryan C, et al. **Brain Res** 1985 Jan;349(1–2):258–62

Inhibition of central angiotensin II induced drinking by GABA in the rat. Hutchinson JS, et al. **Clin Exp Hypertens [A]** 1984; 6(10–11):1777–80

Effects of 6-hydroxydopamine-induced catecholamine depletion on shock-precipitated wall climbing of infant rat pups. Emerich DF, et al. **Dev Psychobiol** 1985 May;18(3):215–27

The benzodiazepine antagonist Ro 15-1788 reverses the effect of methyl-beta-carboline-3-carboxylate but not of harmaline on cerebellar cGMP and motor performance in mice. Burkard WP, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):241–7

Effect of the dopamine D-1 antagonist SCH 23390 on rotational behaviour induced by apomorphine and pergolide in 6-hydroxy-dopamine denervated rats. Herrera-Marschitz M, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):349–54

Dysfunction of the midbrain angular complex can accentuate or attenuate circling behaviour in the rat. Starr MS, et al. **Exp Brain Res** 1985; 58(1):45–55

Tricyclic antidepressants antagonize prostaglandin (PG) E2-induced contractions of the guinea pig ileum and hypomotility in the mouse. Tayo FM. **Experientia** 1985 Apr 15;41(4):474–6

Pharmacologic studies of the central action of zopiclone: effects on locomotor activity and brain monoamines in rats. Liu HJ, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Mar;23(3):121–8

Sulpiride blocks postsynaptic dopamine receptors in the nucleus accumbens. Morgenstern R, et al. **J Neural Transm** 1985; 61(3–4):151–60

SCH23390 causes persistent antidopaminergic effects in vivo: evidence for longterm occupation of receptors. Schulz DW, et al. **Life Sci** 1985 May 20;36(20):1941–8

Development of selective tolerance to the serotonin behavioral syndrome and suppression of locomotor activity after repeated administration of either 5-MeODMT or mCPP. Sills MA, et al. **Life Sci** 1985 Jul 1; 36(26):2463–9

Automating the measurement of locomotor activity. Beninger RJ, et al. **Neurobehav Toxicol Teratol** 1985 Jan–Feb;7(1):79–85

Automated measurement of multivariate locomotor behavior in rodents. Sanberg PR, et al. **Neurobehav Toxicol Teratol** 1985 Jan–Feb; 7(1):87–94

Effect of gestational and neonatal styrene exposure on dopamine receptors. Zaidi NF, et al. **Neurobehav Toxicol Teratol** 1985 Jan–Feb;7(1):23–8

Effects of a thyrotropin releasing hormone analogue on locomotor and other motor activity in the rat. Clarke KA, et al. **Neuropeptides** 1985 Apr;6(2):101–12

The effects of neurotensin and [D-Tyr11]-NT on the hyperactivity induced by intra-accumbens administration of a potent dopamine receptor agonist. Jolicoeur FB, et al. **Neuropeptides** 1985 Apr; 6(2):143-56

Evidence that 2-phenylpyrazolo[4,3-c]-quinolin-3(5H)-one antagonises pharmacological, electrophysiological and biochemical effects of diazepam in rats. Santi M, et al. **Neuropharmacology** 1985 Feb; 24(2):99-105

Treatment of rats with the TRH analog MK-771. Down-regulation of TRH receptors and behavioral tolerance. Simasko SM, et al. **Neuropharmacology** 1985 Feb;24(2):157-65

Behavioral interaction of adenosine and trifluoperazine in mice. DeLong RE, et al. **Neurosci Lett** 1985 Jan 7;53(1):101-7

Detection of homovanillic acid in vivo using microcomputer-controlled voltammetry: simultaneous monitoring of rat motor activity and striatal dopamine release. O'Neill RD, et al. **Neuroscience** 1985 Mar; 14(3):753-63

Hypermotility induced by vasoactive intestinal peptide in the rat: its reciprocal action to cholecystokinin octapeptide. Itoh S, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):53-7

Specificity of nucleus accumbens to activities related to cholecystokinins in rats. Katsuura G, et al. **Peptides (Fayetteville)** 1985 Jan-Feb; 6(1):91-6

Locomotor response of nialamide pretreated old rats to intraaccumbens dopamine. Cousin KM, et al. **Pharmacol Biochem Behav** 1985 Mar; 22(3):461-8

Dopamine-beta-hydroxylase inhibitors, feeding and locomotor activity: reinstatement of feeding following central norepinephrine. Evans KR, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):535-40

Brain amines and effects of chlordiazepoxide on motor activity in response to stress. Freeman GB, et al. **Pharmacol Biochem Behav** 1985 May; 22(5):665-70

Sensitization of rotational behavior produced by a single exposure to cocaine. Guan LC, et al. **Pharmacol Biochem Behav** 1985 May; 22(5):901-3

Effects of phencyclidine (PCP)-like drugs on turning behavior, 3H-dopamine uptake, and 3H-PCP binding. Johnson KM, et al. **Pharmacol Biochem Behav** 1985 May;22(5):731-5

Hypothalamic involvement in the locomotor stimulant or satiety action of thyrotropin-releasing hormone and amphetamine. Shian LR, et al. **Pharmacology** 1985;30(5):259-65

Development of mouse activity, stimulus reactivity, habituation, and response to amphetamine and scopolamine. Alleva E, et al. **Physiol Behav** 1985 Apr;34(4):519-23

Serotonin and schizophrenia: correlations between serotonergic activity and schizophrenic motor behavior. King R, et al. **Psychiatry Res** 1985 Mar;14(3):235-40

Behavioral analysis of the effect of neurotensin injected into the ventral mesencephalon on investigatory and spontaneous motor behavior in the rat. Cador M, et al. **Psychopharmacology (Berlin)** 1985;85(2):187-96

Increased or decreased locomotor response in rats following repeated administration of apomorphine depends on dosage interval. Castro R, et al. **Psychopharmacology (Berlin)** 1985;85(3):333-9

A comparison between chlordiazepoxide and CL 218,872--a synthetic nonbenzodiazepine ligand for benzodiazepine receptors on spontaneous locomotor activity in rats. McElroy JF, et al. **Psychopharmacology (Berlin)** 1985;85(2):224-6

The tail suspension test: a new method for screening antidepressants in mice. Steru L, et al. **Psychopharmacology (Berlin)** 1985;85(3):367-70

Induction and reversal of dopamine dyskinesia in rat, cat, and monkey. Lloyd KG, et al. **Psychopharmacology [Suppl]** 1985;2:200-10

Regional brain dopamine metabolism: a marker for the speed, direction, and posture of moving animals. Freed CR, et al. **Science** 1985 Jul 5; 229(4708):62-5

Paradoxical sleep deprivation and the immobility response in the rat: effects of desipramine and phentolamine. van Luijtelaar EL, et al. **Sleep** 1985;8(1):49-55

[Appraisal of ultradian components in the ethosecretogram of rat] Shiraishi I. **Hokkaido Igaku Zasshi** 1985 Jan;60(1):66-81 (Eng. Abstr.) **(Jpn)**

[TRH and its analog (DN-1417). Effects on central dopaminergic system-dependent behaviors in rats and mice] Miyamoto M, et al. **Nippon Yakurigaku Zasshi** 1985 Mar;85(3):129-41 (Eng. Abstr.) **(Jpn)**

MOTOR SKILLS

Dopamine depletion in a striatal subregion disrupts performance of a skilled motor task in the rat. Sabol KE, et al. **Brain Res** 1985 May 27;335(1):33-43

Sensitivity changes to dopaminergic agents in fine motor control of rhesus monkeys after repeated methamphetamine administration. Ando K, et al. **Pharmacol Biochem Behav** 1985 May;22(5):737-43

The anxiolytic activity of beta-carboline derivatives in mice, and its separation from ataxic properties. Stephens DN, et al. **Pharmacopsychiatry** 1985 Jan;18(1):167-70

MSH

Distribution of the pro-opiomelanocortin derived peptides, adrenocorticotrope hormone, alpha-melanocyte-stimulating hormone and beta-endorphin (ACTH, alpha-MSH, beta-END) in the rat hypothalamus. Mezey E, et al. **Brain Res** 1985 Mar 4;328(2):341-7

Cyclic melanotropins. 9. 7-D-Phenylalanine analogues of the active-site sequence. Cody WL, et al. **J Med Chem** 1985 May;28(5):583-8

Photoaffinity labelling of MSH receptors on Anolis melanophores: effects of catecholamines, calcium and forskolin. Eberle AN, et al. **J Recept Res** 1985;5(1):59-81

Opiomelanocortins and behavioral adaptation. Bohus B. **Pharmacol Ther** 1984;26(3):417-51 (238 ref.)

NEUROREGULATORS

Catecholamine and opioid receptors, presynaptic inhibition of CNS neurotransmitter release, and adenylate cyclase. Mulder AH, et al. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:273-86

Adenosine, adenylate cyclase, and transmitter release. Phillis JW, et al. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:243-57 (81 ref.)

Neuroendocrinology and the ovulation cycle--advances and review. Schnatz PT. **Adv Psychosom Med** 1985;12:4-24

Psychoendocrinology and the menstrual cycle. Youngs DD, et al. **Adv Psychosom Med** 1985;12:25-34

Delta 1-pyrroline-5-carboxylate dehydrogenase, a possible regulatory enzyme in transmitter glutamic acid metabolism--a preliminary report. Wong PT, et al. **Ann Acad Med Singapore** 1985 Jan;14(1):143-6

Membrane-related effects of atypical antidepressants. Valdman AV, et al. **Ann Ist Super Sanita** 1984;20(1):65-72

Accumulation of inositol phosphates in sympathetic ganglia. Effects of depolarization and of amine and peptide neurotransmitters. Bone EA, et al. **Biochem J** 1985 Apr 1;227(1):263-9

Release of D-[3H]aspartic acid from the rat striatum. Effect of veratridine-evoked depolarization, fronto-parietal cortex ablation, and striatal lesions with kainic acid. Arqueros L, et al. **Biochem Pharmacol** 1985 Apr 15;34(8):1217-24

Monoamine metabolites: their relationship and lack of relationship to monoaminergic neuronal activity. Commissiong JW. **Biochem Pharmacol** 1985 Apr 15;34(8):1127-31

Interaction of phenothiazine drugs with human ceruloplasmin. Relation between activation of catecholamine neurotransmitter oxidation and electron donating ability of phenothiazine drugs. de Mol NJ. **Biochem Pharmacol** 1985 Aug 1;34(15):2605-9

Animal models of depression: parallels and correlates to severe depression in humans. Jesberger JA, et al. **Biol Psychiatry** 1985 Jul; 20(7):764-84

The role of substance P as a neurotransmitter in the reflexes of slow time courses in the neonatal rat spinal cord. Akagi H, et al. **Br J Pharmacol** 1985 Mar;84(3):663-73

Electrophysiological evidence that nipecotic acid can be used in vivo as a false transmitter. Lerma J, et al. **Brain Res** 1985 Jun 3; 335(2):377-80

Evidence for genetic influences on neurotransmitter content of identified neurones of Lymnaea stagnalis. Audesirk G, et al. **Comp Biochem Physiol [C]** 1985;81(1):57-60

Motor and behavioural effects induced by putative neurotransmitter injection into the optic lobe of the cuttlefish, Sepia officinalis. Chichery R, et al. **Comp Biochem Physiol [C]** 1985;80(2):415-9

The effects of putative amino acid neurotransmitters on somata isolated from neurons of the locust central nervous system. Giles D, et al. **Comp Biochem Physiol [C]** 1985;80(2):231-6

Neurotransmitter precursors and metabolites in CSF of human neonates. Anderson GM, et al. **Dev Med Child Neurol** 1985 Apr;27(2):207-14

Neurotransmitters involved in mediating the steroid-dependent suppression of pulsatile luteinizing hormone secretion in anestrous ewes: effects of receptor antagonists. Meyer SL, et al. **Endocrinology** 1985 May;116(5):2054-61

Evidence that ATP is involved as a co-transmitter in the hypogastric nerve supplying the seminal vesicle of the guinea-pig. Meldrum LA, et al. **Eur J Pharmacol** 1985 Apr 16;110(3):363-6

Phorbol ester and calcium act synergistically to enhance neurotransmitter release by brain neurons in culture. Zurgil N, et al. **FEBS Lett** 1985 Jun 17;185(2):257-61

Arterial and cardiopulmonary reflexes in the regulation of the neurohumoral drive to the circulation. Bishop VS, et al. **Fed Proc** 1985 May;44(8):2377-81 (31 ref.)

Vasoactive intestinal peptide. Relaxant neurotransmitter in tenia coli of the guinea pig. Grider JR, et al. **Gastroenterology** 1985 Jul; 89(1):36-42

Identification of putative neurotransmitters in the lizard parietal eye. Engbretson GA, et al. **Invest Ophthalmol Vis Sci** 1985 May; 26(5):670-8

Blood pressure control by neurotransmitters in the medulla oblongata and spinal cord. Howe PR. **J Auton Nerv Syst** 1985 Feb-Mar; 12(2-3):95-115

Determination of neurotransmitter amino acids by high-performance liquid chromatography with fluorescence detection. Zecca L, et al. **J Chromatogr** 1985 Feb 8;337(2):391-6

Role of calcium and phosphoinositides in the actions of certain hormones and neurotransmitters. Exton JH. **J Clin Invest** 1985 Jun; 75(6):1753-7 (59 ref.)

Fine structure of peptidergic and catecholaminergic nerve fibers in the anterior cerebral artery and their interrelationship: an immunoelectron microscopic study. Matsuyama T, et al. **J Comp Neurol** 1985 May 8; 235(2):268-76

Immunohistochemical demonstration of some putative neurotransmitters in the lamprey spinal cord and spinal ganglia: 5-hydroxytryptamine-, tachykinin-, and neuropeptide-Y-immunoreactive neurons and fibers. Van Dongen PA, et al. **J Comp Neurol** 1985 Apr 22;234(4):501-22

Insect cardioactive peptides. II. Neurohormonal control of heart activity by two cardioacceleratory peptides in the tobacco hawkmoth, Manduca sexta. Tublitz NJ, et al. **J Exp Biol** 1985 Jan;114:381-95

Distribution of aminergic neurons in the brain of the sterlet, Acipenser ruthenus (Chondrostei, Actinopterygii). Kotrschal K, et al. **J Hirnforsch** 1985;26(1):65-72

Neuropeptides and other mediators in the central nervous system. Bloom FE. **J Immunol** 1985 Aug;135(2 Suppl):743s-745s

Noradrenergic and peptidergic innervation of lymphoid tissue. Felten DL, et al. **J Immunol** 1985 Aug;135(2 Suppl):755s-765s (73 ref.)

Evidence that thymosins and other biologic response modifiers can function as neuroactive immunotransmitters. Hall NR, et al. **J Immunol** 1985 Aug;135(2 Suppl):806s-811s

Cellular interactions at the central and peripheral terminals of primary sensory neurons. Jessell TM. **J Immunol** 1985 Aug; 135(2 Suppl):746s-749s

Modulation of macrophage-mediated tumoricidal activity by neuropeptides and neurohormones. Koff WC, et al. **J Immunol** 1985 Jul;135(1):350-4

Neuroanatomic and neurotransmitter influences on immune function. Roszman TL, et al. **J Immunol** 1985 Aug;135(2 Suppl):769s-772s

Evolutionary origins of neuropeptides, hormones, and receptors: possible applications to immunology. Roth J, et al. **J Immunol** 1985 Aug; 135(2 Suppl):816s-819s

An excitant amino acid projection from the medial prefrontal cortex to the anterior part of nucleus accumbens in the rat. Christie MJ, et al. **J Neurochem** 1985 Aug;45(2):477-82

Composite technique for regional neurochemical studies: measurement of energy and neurotransmitter metabolites in single tissue sample. Djuricic BM, et al. **J Neurochem** 1985 Jun;44(6):1920-4

Some long-lasting neurochemical effects of prenatal or early postnatal exposure to diazepam. Frieder B, et al. **J Neurochem** 1985 Jul; 45(1):37-42

Rat serum contains a developmentally regulated cholinergic inducing activity. Wolinsky EJ, et al. **J Neurosci** 1985 Jun;5(6):1509-12

Expression of noradrenergic and cholinergic traits by sympathetic neurons cultured without serum. Wolinsky EJ, et al. **J Neurosci** 1985 Jun; 5(6):1497-508

Profiles of evoked release along the length of frog motor nerve terminals. D'Alonzo AJ, et al. **J Physiol (Lond)** 1985 Feb;359:235-58

Long-term potentiation of transmitter release induced by repetitive presynaptic activities in bull-frog sympathetic ganglia. Koyano K, et al. **J Physiol (Lond)** 1985 Feb;359:219-33

Burn trauma induces anorexia and aberrations in CNS amine neurotransmitters. Chance WT, et al. **J Trauma** 1985 Jun; 25(6):501-7

Modulation of receptor sensitivity and action potentials by transmitters in vertebrate neurones. Koketsu K. **Jpn J Physiol** 1984;34(6):945-60 (59 ref.)

Proctolin: a potent inhibitor of aminoenkephalinase. Hui KS, et al. **Life Sci** 1985 Jun 17;36(24):2309-15

Tuning in to neurotransmitters [news] Altman J. **Nature** 1985 Jun 13-19; 315(6020):537

Pertussis toxin reverses adenosine inhibition of neuronal glutamate release. Dolphin AC, et al. **Nature** 1985 Jul 11-17;316(6024):148-50

Transport of monoamine and amino acid neurotransmitters by primary astroglial cultures. Hansson E. **Neurochem Res** 1985 May; 10(5):667-75

Selective retrograde labeling in some afferents to the rabbit lateral geniculate nucleus following injections of tritiated neurotransmitter-related compounds. Matute C, et al. **Neurosci Lett** 1985 Jan 7;53(1):9-14

Simultaneous monitoring of voltammetric and ion-selective electrodes in mammalian brain. Nagy G, et al. **Neurosci Lett** 1985 Apr 9; 55(2):119-24

Prolonged non-adrenergic inhibition of cardiac vagal action following sympathetic stimulation: neuromodulation by neuropeptide Y? Potter EK. **Neurosci Lett** 1985 Mar 15;54(2-3):117-21

Effects of chlordecone on neuroendocrine function of female rats. Uphouse L. **Neurotoxicology (Little Rock Ar)** 1985 Spring; 6(1):191-210 (80 ref.)

Sympathetic neuron density differentially regulates transmitter phenotypic expression in culture. Adler JE, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(12):4296-300

N-Acetylaspartylglutamate: possible role as the neurotransmitter of the lateral olfactory tract. Ffrench-Mullen JM, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(11):3897-900

Intraterminal injection of synapsin I or calcium/calmodulin-dependent protein kinase II alters neurotransmitter release at the squid giant synapse. Llinás R, et al. **Proc Natl Acad Sci USA** 1985 May; 82(9):3035-9

Roles for neurotransmitters in development: possible interaction with drugs during the fetal and neonatal periods. Lauder JM. **Prog Clin Biol Res** 1985;163C:375-80

Neurotropic drugs and brain development: effects on cell replication in vivo and in vitro. Patel AJ. **Prog Clin Biol Res** 1985;163C:301-5

Role of neurotransmitters and teratogens on palate development. Zimmerman EF, et al. **Prog Clin Biol Res** 1985;163C:405-8

Biochemical hypotheses of premenstrual tension syndrome. Janowsky DS, et al. **Psychol Med** 1985 Feb;15(1):3-8

Glutamine-induced alterations in the content of brain amino acid neurotransmitters in rats with different alcohol motivation. Ostrovsky SYu. **Subst Alcohol Actions Misuse** 1984;5(5):247-53

Retinal neurotransmission. Pycock CJ. **Surv Ophthalmol** 1985 Mar-Apr; 29(5):335-65

[Central neurotransmitters and cardiovascular activity] Xia Y. **Sheng Li Ko Hsueh Chin Chan** 1985 Jan;16(1):27-31 (50 ref.) **(Chi)**

NEUROTENSIN

Immunohistochemical localization of neurotensin in hamster adrenal medulla. Pelto-Huikko M, et al. **Anat Rec** 1985 Apr;211(4):458-64

Dopamine D2 receptors modulate neurotransmitter-regulated calcium ion gates. Memo M, et al. **Ann Ist Super Sanita** 1984;20(1):5-10

Neurotensin degradation by soluble and membrane-associated enzymes from the brain. Emson PC, et al. **Biochem Soc Trans** 1985 Feb; 13(1):53-4

The effects of chronic neuroleptic treatment on neurotensin-like immunoreactivity in the rat central nervous system. Goedert M, et al. **Brain Res** 1985 Jun 3;335(2):334-6

The ontogenetic development of neurotensin-like immunoreactivity and neurotensin receptors in the cat striatum. Goedert M, et al. **Brain Res** 1985 May;352(1):127-31

Immunohistochemical localization of neurotensin and beta-endorphin in the rat anterior pituitary gland. Miyoshi R, et al. **Brain Res** 1985 Apr 8;331(2):386-8

A quantitative, immunochemical demonstration of the postnatal development of neurotensin in the medial preoptic area of the rat. Wolfson B, et al. **Brain Res** 1985 Feb;350(1-2):241-50

Vascular actions of VIP, substance P and neurotensin on the isolated perfused human fetal placenta. de Moura RS, et al. **Contrib Gynecol Obstet** 1985;13:174-5

Changes in neurotensin-like immunoreactivity during menopausal hot flashes. Kronenberg F, et al. **J Clin Endocrinol Metab** 1985 Jun; 60(6):1081-6

Neurotensin enhances estradiol induced DNA synthesis in immature rat uterus. Mistry A, et al. **Life Sci** 1985 May 27;36(21):2063-7

Ultrastructural immunocytochemical studies on CCK-and neurotensin-like immunoreactivity in the nucleus accumbens of the rat. Johansson O, et al. **Med Biol** 1984;62(6):318-22

The effects of neurotensin and [D-Tyr11]-NT on the hyperactivity induced by intra-accumbens administration of a potent dopamine receptor agonist. Jolicoeur FB, et al. **Neuropeptides** 1985 Apr; 6(2):143-56

Release of mast cell mediators, vasoconstriction and edema in the isolated, perfused head of the rat following intracarotid infusion of neurotensin. Rioux F, et al. **Neuropeptides** 1985 Mar;6(1):1–12

Behavioral analysis of the effect of neurotensin injected into the ventral mesencephalon on investigatory and spontaneous motor behavior in the rat. Cador M, et al. **Psychopharmacology (Berlin)** 1985;85(2):187–96

Bombesin, neurotensin and pro-gamma-melanotropin immunoreactants in human milk. Ekman R, et al. **Regul Pept** 1985 Mar; 10(2–3):99–105

[Gastrointestinal hormones and related peptides. V. Neurotensin] Sadowska-Krowicka H, et al. **Postepy Hig Med Dosw** 1984 Jul–Aug; 38(4):535–52 (110 ref.) (Eng. Abstr.) **(Pol)**

[Cyclic AMP content of the blood, brain, stomach, adrenals and duodenum after administration of neurotensin and cholecystokinin] Andreanova MV, et al. **Fiziol Zh SSSR** 1985 Feb;71(2):258–61 **(Rus)**

[Effect of natural neurotensin and its analog on gastric secretion and levels of various peptides in dog blood] Barashkova GM, et al. **Fiziol Zh SSSR** 1985 Feb;71(2):200–5 (Eng. Abstr.) **(Rus)**

NEUROTIC DISORDERS

Neuroticism and personality disorder in depression. Davidson J, et al. **J Affective Disord** 1985 Mar–Apr;8(2):177–82

Behavioural and endocrine reactions in boys scoring high on Sennton neurotic scale viewing an exciting and partly violent movie and the importance of social support. Arnetz BB, et al. **Soc Sci Med** 1985; 20(7):731–6

NIALAMIDE

Locomotor response of nialamide pretreated old rats to intraaccumbens dopamine. Cousin KM, et al. **Pharmacol Biochem Behav** 1985 Mar; 22(3):461–8

NOREPINEPHRINE

Effect of propranolol on post-traumatic hypophosphataemia and catecholamine secretion. Lovén L, et al. **Acta Chir Scand** 1985; 151(3):201–4

Changes in blood level of catecholamines during arterial blood pressure rise induced with sciatic nerve stimulation. Całkosiński I, et al. **Acta Physiol Pol** 1984 Jan–Feb;35(1):47–51

Seasonal changes in blood lipids, adrenaline, noradrenaline, glucose and insulin in Norwegian reindeer. Larsen TS, et al. **Acta Physiol Scand** 1985 May;124(1):53–9

Noradrenergic modulation of cerebral cortical oxidative metabolism. LaManna JC, et al. **Adv Exp Med Biol** 1984;180:211–9

Effect of a benzodiazepine (alprazolam) on plasma epinephrine and norepinephrine levels during exercise stress. Stratton JR, et al. **Am J Cardiol** 1985 Jul 1;56(1):136–9

Norepinephrine in cochlear microcirculation of guinea pigs. Matsunaga T, et al. **Am J Otolaryngol** 1985 May–Jun;6(3):226–30

Decidua-associated changes in guinea pig uterine blood flow and volume: relation to uterine norepinephrine concentrations. Garris DR, et al. **Anat Rec** 1985 Apr;211(4):410–13

The modulation of acetylcholine release by noradrenaline, GABA and related compounds. Beani L, et al. **Ann Ist Super Sanita** 1984; 20(1):17–9

Noradrenergic modulation of selective attention: its role in memory retrieval. Sara SJ. **Ann NY Acad Sci** 1985;444:178–93

Selective decrease of hypothalamic noradrenaline by cysteamine. Vécsei L, et al. **Arch Int Pharmacodyn Ther** 1985 Mar;274(1):125–8

Depletion of adrenal catecholamines alters the amnestic effect of amygdala stimulation. Bennett C, et al. **Behav Brain Res** 1985 Apr;15(2):83–91

Studies on the mechanism of inhibition of glucose-stimulated insulin secretion by noradrenaline in rat islets of Langerhans. Morgan NG, et al. **Biochem J** 1985 Mar 1;226(2):571–6

Catecholamine responses to changes in posture during human pregnancy. Whittaker PG, et al. **Br J Obstet Gynaecol** 1985 Jun;92(6):586–92

The formation of deaminated metabolites of dopamine in the locus coeruleus depends upon noradrenergic neuronal activity. Curet O, et al. **Brain Res** 1985 Jun 3;335(2):297–301

The prefrontal 'cortex' in the pigeon. Biochemical evidence. Divac I, et al. **Brain Res** 1985 Apr 22;332(2):363–8

Comparative effects of sciatic nerve stimulation, blood pressure, and morphine on the activity of A5 and A6 pontine noradrenergic neurons. Guyenet PG, et al. **Brain Res** 1985 Feb 18;327(1–2):191–201

Central noradrenergic involvement in yohimbine excitation of acoustic startle: effects of DSP4 and 6-OHDA. Kehne JH, et al. **Brain Res** 1985 Mar 18;330(1):31–41

Neonatal 6-hydroxydopamine lesion of spinal norepinephrine terminals fails to affect the ontogeny of swimming behavior. Ryan C, et al. **Brain Res** 1985 Jan;349(1–2):258–62

The postnatal development of norepinephrine-stimulated cyclic AMP accumulation in rat spinal cord. Simmons K, et al. **Brain Res** 1985 Feb; 350(1–2):306–10

Aversive effects of subcutaneously injected vasopressin in the rat: independence of the ascending dorsal noradrenergic bundle. Tam FW, et al. **Brain Res** 1985 Jun 24;337(1):133–7

Inputs from the A1 noradrenergic region to hypothalamic paraventricular neurons in the rat. Tanaka J, et al. **Brain Res** 1985 Jun 3; 335(2):368–71

Epinephrine- and norepinephrine-evoked potential changes of frog primary afferent terminals: pharmacological characterization of alpha and beta components. Wohlberg CJ, et al. **Brain Res** 1985 Feb 18; 327(1–2):289–301

Mechanisms of supersensitivity to sympathomimetic amines in the chronically denervated heart of the conscious dog. Vatner DE, et al. **Circ Res** 1985 Jul;57(1):55–64

Effect of intracerebroventricular 6-hydroxydopamine (6-HODA) on the angiotensinogen concentration of the brain. Basso N, et al. **Clin Exp Hypertens** [A] 1984;6(10–11):1773–6

Effects of angiotensin II and ACE inhibitors on electrically stimulated noradrenaline release from superfused rat brain slices. Schacht U. **Clin Exp Hypertens** [A] 1984;6(10–11):1847–51

Accumulation of intra-arterially administered [3H]adrenaline and [3H]noradrenaline in various tissues of the Atlantic cod, Gadus morhua. Ungell AL. **Comp Biochem Physiol** [C] 1985;81(1):25–8

Norepinephrine alone versus norepinephrine plus low-dose dopamine: enhanced renal blood flow with combination pressor therapy. Schaer GL, et al. **Crit Care Med** 1985 Jun;13(6):492–6

Effects of 6-hydroxydopamine-induced catecholamine depletion on shock-precipitated wall climbing of infant rat pups. Emerich DF, et al. **Dev Psychobiol** 1985 May;18(3):215–27

Regulation of ketogenesis by epinephrine and norepinephrine in the overnight-fasted, conscious dog. Steiner KE, et al. **Diabetes** 1985 May; 34(5):425–32

Strain differences in brain biogenic amines concentration in rats with different resistance to emotional stress. Sudakov KV, et al. **Endocrinol Exp (Bratisl)** 1985 Mar;19(1):39–45

Plasma glucagon and catecholamines during exhaustive short-term exercise. Näveri H, et al. **Eur J Applied Physiol** 1985;53(4):308–11

Differences in dopamine- and noradrenaline-induced amylase release from the rat parotid gland. Sundström S, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):355–61

Response of phasically firing paraventricular neurons to A1 noradrenergic region stimulation and its attenuation by adrenoceptor antagonists. Tanaka J, et al. **Exp Neurol** 1985 Jun;88(3):714–25

Plasma catecholamine and blood lactate cumulation during incremental exhaustive exercise. Lehmann M, et al. **Int J Sports Med** 1985 Apr; 6(2):78–81

Heat acclimation: role of norepinephrine in the anterior hypothalamus. Christman JV, et al. **J Appl Physiol** 1985 Jun;58(6):1923–8

Exercise, dobutamine, and combined atropine, norepinephrine, and epinephrine compared. Haidet GC, et al. **J Appl Physiol** 1985 Jun; 58(6):2047–53

Cardiovascular effects of intracisternal 6-hydroxydopamine and of subsequent lesions of the ventrolateral medulla coinciding with the Al group of noradrenaline cells in the rabbit. Elliott JM, et al. **J Auton Nerv Syst** 1985 Feb–Mar;12(2–3):117–30

Role of central nervous system monoamines in cardiopulmonary effects of Althesin in rabbit and man. Quail AW, et al. **J Auton Nerv Syst** 1985 Feb–Mar;12(2–3):159–74

Ambient temperature modulates the differentiated cardiorespiratory pattern generated by the central noradrenergic system, most likely via alterations of thyrotropin-releasing hormone (TRH) activity. Riedel W. **J Auton Nerv Syst** 1985 Feb–Mar;12(2–3):145–57

Central nervous system 5-hydroxytryptamine and noradrenaline specificity of ear vascular and ventilation reflexes in thermoregulating rabbits. White SW, et al. **J Auton Nerv Syst** 1985 Feb–Mar; 12(2–3):131–44

Rapid changes in synaptic vesicle cytochemistry after depolarization of cultured cholinergic sympathetic neurons. Johnson MI, et al. **J Cell Biol** 1985 Jul;101(1):217–26

Pial artery responses to norepinephrine potentiated by endothelium removal. Sercombe R, et al. **J Cereb Blood Flow Metab** 1985 Jun; 5(2):312–7

Simultaneous assay of 3,4-dihydroxyphenylethylene glycol and norepinephrine in human plasma by high-performance liquid chromatography with electrochemical detection. Howes LG, et al. **J Chromatogr** 1985 Mar 22;338(2):401–3

Simple and fast analysis of adrenaline and noradrenaline in plasma on microbore high-performance liquid chromatography columns using fluorimetric detection. Kamperman G, et al. **J Chromatogr** 1985 Feb 8;337(2):384–90

Circadian rhythms of epinephrine and norepinephrine in man. Linsell CR, et al. **J Clin Endocrinol Metab** 1985 Jun;60(6):1210–5

Modulation of calcium channels by norepinephrine in internally dialyzed avian sensory neurons. Forscher P, et al. **J Gen Physiol** 1985 May; 85(5):743–63

Effect of norepinephrine on swelling-induced potassium transport in duck red cells. Evidence against a volume-regulatory decrease under physiological conditions. Haas M, et al. **J Gen Physiol** 1985 May; 85(5):649–67

BIBLIOGRAPHY

Norepinephrine as a possible transmitter involved in synaptic transmission in frog taste organs and Ca dependence of its release. Nagahama S, et al. **J Gen Physiol** 1985 Mar;85(3):431-42

Pressor responsiveness to norepinephrine in rabbits with adrenal perturbations. Siripaisarnpipat S, et al. **J Hypertens** 1985 Feb; 3(1):89-96

Neurochemical profile of Lu 19-005, a potent inhibitor of uptake of dopamine, noradrenaline, and serotonin. Hyttel J, et al. **J Neurochem** 1985 May;44(5):1615-22

Assessment of noradrenaline and 5-hydroxytryptamine uptake in intact rat brain. Wyllie MG, et al. **J Neurochem** 1985 Aug;45(2):456-60

Denervation supersensitivity of the rat pineal to norepinephrine-stimulated [3H]inositide turnover revealed by lithium and a convenient procedure. Zatz M. **J Neurochem** 1985 Jul; 45(1):95-100

Dopamine beta-hydroxylase-like immunoreactivity in the rat and cat carotid body: a light and electron microscopic study. Chen IL, et al. **J Neurocytol** 1985 Feb;14(1):131-44

Effect of immune complex-forming reactants on catecholamine-modulated behaviors in the rat hypothalamus. Schupf N, et al. **J Neuroimmunol** 1985 Jul;9(1-2):13-27

Measurement of noradrenaline synthesis in rat hippocampal synaptosomes using HPLC with ECD. Birch PJ, et al. **J Neurosci Methods** 1985 May; 13(3-4):231-8

A technique for the microinjection of macromolecules into viable chromaffin cells in culture. Kenigsberg RL, et al. **J Neurosci Methods** 1985 Apr;13(2):103-18

Inhibition by 5,6-dihydroxy-2-dimethylaminotetralin (M7) of noradrenergic neurotransmission in the rabbit hypothalamus: role of alpha-2 adrenoceptors and of dopamine receptors. Galzin AM, et al. **J Pharmacol Exp Ther** 1985 May;233(2):459-65

Adrenergic and possible nonadrenergic sources of adenosine 5'-triphosphate release from nerve varicosities isolated from ileal myenteric plexus. Al-Humayyd M, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):796-800

Inhibitory effects of norepinephrine, methoxamine and phenylephrine on renin release from rat kidney cortical slices. Matsumura Y, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):782-7

Chronic thyroxine treatment of rats down-regulates the noradrenergic cyclic AMP generating system in cerebral cortex. Schmidt BH, et al. **J Pharmacol Exp Ther** 1985 May;233(2):466-72

Demonstration of an alpha adrenoceptor-mediated inotropic effect of norepinephrine in human atria. Skomedal T, et al. **J Pharmacol Exp Ther** 1985 May;233(2):441-6

Reduction of the cyclic adenosine 3',5'-monophosphate response to catecholamines in rat brain slices after repeated restraint stress. Stone EA, et al. **J Pharmacol Exp Ther** 1985 May;233(2):382-8

Noradrenaline hyperpolarization and depolarization in cat vesical parasympathetic neurones. Akasu T, et al. **J Physiol (Lond)** 1985 Apr; 361:165-84

Efflux of 5-hydroxytryptamine and noradrenaline into spinal cord superfusates during stimulation of the rat medulla. Hammond DL, et al. **J Physiol (Lond)** 1985 Feb;359:151-62

Methionine-enkephalin inhibits stress-induced increases in noradrenaline turnover in brain regions of rats. Tanaka M, et al. **Jpn J Pharmacol** 1985 Jan;37(1):117-9

Inhibition of locus coeruleus neuronal activity by beta-phenylethylamine. Lundberg PA, et al. **Life Sci** 1985 May 13;36(19):1889-96

Epinephrine and norepinephrine syntheses are regulated by a glucocorticoid receptor-mediated mechanism in the bovine adrenal medulla. Nawata H, et al. **Life Sci** 1985 May 20;36(20):1957-66

Norepinephrine-dependent and independent mechanisms of persistent effects of amphetamine in rat cerebellum. Sorensen SM, et al. **Life Sci** 1985 Jun 24;36(25):2383-9

Enhancement of the pressor response to norepinephrine by angiotensin in the conscious rabbit. Weber MA, et al. **Life Sci** 1985 May 20; 36(20):1897-907

Excretion of urinary catecholamines and plasma cortisol levels in female nurses on short-rotating shift. Panza G, et al. **Med Lav** 1985 Jan-Feb; 76(1):30-4

Pharmacology in vivo of the phenylindan derivative, Lu 19-005, a new potent inhibitor of dopamine, noradrenaline and 5-hydroxytryptamine uptake in rat brain. Arnt J, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):101-7

Plasma catecholamines in arterial and capillary blood. Baumgartner H, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):461-3

Effects of clorgyline and (-)deprenyl on the deamination of normetanephrine and noradrenaline in strips and homogenates of the canine saphenous vein. Caramona MM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):396-400

Influence of MAO A and MAO B on the inactivation of noradrenaline in the saphenous vein of the dog. Caramona MM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):401-6

Cardiac glycosides, calcium and the release of neurotransmitter from peripheral noradrenergic nerves. Tan CM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Mar;329(1):1-8

Electroacupuncture alters catecholamines in brain regions of rats. Sun AY, et al. **Neurochem Res** 1985 Feb;10(2):251-8

Medial preoptic area involvement in norepinephrine-induced suppression of pulsatile luteinizing hormone release in ovariectomized rats. Leipheimer RE, et al. **Neuroendocrinology** 1985 Apr;40(4):345-51

Effects of lithium in vitro on noradrenaline-induced cyclic AMP accumulation in rat cortical slices after reserpine-induced supersensitivity. Newman ME, et al. **Neuropharmacology** 1985 Apr; 24(4):353-5

Stress and brain noradrenaline: a review. Glavin GB. **Neurosci Biobehav Rev** 1985 Summer;9(2):233-43 (81 ref.)

The role of noradrenaline in tuning and dopamine in switching between signals in the CNS. Oades RD. **Neurosci Biobehav Rev** 1985 Summer; 9(2):261-82

Temporal relationship between noradrenaline release in the central amygdala and plasma noradrenaline secretion in rats and tree shrews. Dietl H. **Neurosci Lett** 1985 Mar 22;55(1):41-6

Astrocyte opioid receptors: activation modifies the noradrenaline-evoked increase in 2-[14C]deoxyglucose incorporation into glycogen. Pearce B, et al. **Neurosci Lett** 1985 Apr 9;55(2):157-60

Effect of histamine infusion on circulating methionine-enkephalin and catecholamine concentrations. Smith R, et al. **Neurosci Lett** 1985 Apr 19;55(3):289-92

Relative pre- and postjunctional roles of noradrenaline and adenosine 5'-triphosphate as neurotransmitters of the sympathetic nerves of guinea-pig and mouse vas deferens. Stjärne L, et al. **Neuroscience** 1985 Mar;14(3):929-46

alpha 1- and beta-adrenergic receptors are co-regulated during both noradrenergic denervation and hyperinnervation. Sutin J, et al. **Neuroscience** 1985 Apr;14(4):973-80

Dopamine-beta-hydroxylase inhibitors, feeding and locomotor activity: reinstatement of feeding following central norepinephrine. Evans KR, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):535-40

Effect of a low sodium medium, ouabain and noradrenaline on relaxation of the myocardium of the perfused rabbit heart. Fišer B, et al. **Physiol Bohemoslov** 1985;34(1):77-84

The influence of prazosin on E. coli lipopolysaccharide-induced fever and noradrenaline hyperthermia. Matuszek M, et al. **Pol J Pharmacol Pharm** 1984 Nov-Dec;36(6):585-93

Some behavioral effects of microinjections of serotonin and noradrenaline into the limbic structures of the rat brain. Płaźnik A. **Pol J Pharmacol Pharm** 1984 Sep-Oct;36(5):541-54

The effects of lesions of the locus coeruleus and treatment with drugs affecting brain noradrenergic neurotransmission on dominant-subordinate behavior in rats competing for water. Plewako M, et al. **Pol J Pharmacol Pharm** 1984 Sep-Oct;36(5):555-60

The role of the central noradrenaline system in regulating neuronal plasticity in the developing neocortex. Kasamatsu T. **Prog Clin Biol Res** 1985;163C:369-73

Hypophysectomy disturbs the noradrenergic feeding system of the paraventricular nucleus. Roland CR, et al. **Psychoneuroendocrinology** 1985;10(1):109-20

Supersensitivity to the anticonvulsant and proconvulsant activity of clonidine following noradrenaline depletion induced by 6-hydroxydopamine. Dalton JC, et al. **Psychopharmacology (Berlin)** 1985;85(3):319-22

The effect of clorgyline on noradrenergic function. Ross RJ, et al. **Psychopharmacology (Berlin)** 1985;85(2):227-30

Airway responses to low concentrations of adrenaline and noradrenaline in normal subjects. Berkin KE, et al. **Q J Exp Physiol** 1985 Apr; 70(2):203-9

Relationship between sleep efficiency and urinary excretion of catecholamines in bed-rested humans. Nishihara K, et al. **Sleep** 1985; 8(2):110-7

Behavioural and endocrine reactions in boys scoring high on Sennton neurotic scale viewing an exciting and partly violent movie and the importance of social support. Arnetz BB, et al. **Soc Sci Med** 1985; 20(7):731-6

NORMETANEPHRINE

Normetanephrine and metanephrine oxidized by both types of monoamine oxidase. Suzuki O, et al. **Experientia** 1985 May 15;41(5):634-6

Effects of clorgyline and (-)deprenyl on the deamination of normetanephrine and noradrenaline in strips and homogenates of the canine saphenous vein. Caramona MM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):396-400

NORTRIPTYLINE

Monitoring plasma concentration of nortriptyline. Methodological, pharmakokinetic and clinical aspects. Kragh-Sørensen P. **Dan Med Bull** 1985 Mar;32(1):29-53

Plasma nortriptyline and clinical response in depression. Murphy GE, et al. **J Affective Disord** 1985 Mar-Apr;8(2):123-9

Child and adolescent nortriptyline single dose kinetics predict steady state plasma levels and suggested dose: preliminary data. Geller B, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):154-8

Structural analysis of the epitope recognized by a monoclonal antibody directed against tricyclic antidepressants. Marullo S, et al. **J Immunol** 1985 Jul;135(1):471-7

OBSESSIVE-COMPULSIVE DISORDER

Two cases of obsessive-compulsive disorder with depression responsive to trazodone. Baxter LR Jr. **J Nerv Ment Dis** 1985 Jul;173(7):432-3

Obsessive-compulsive disorder. Insel TR. **Psychiatr Clin North Am** 1985 Mar;8(1):105-17 (85 ref.)

Clomipramine and imipramine in obsessive-compulsive disorder. Volavka J, et al. **Psychiatry Res** 1985 Jan;14(1):85-93

[Treatment of obsessive compulsive neurosis] Greenberg D, et al. **Harefuah** 1985 Mar 1;108(5):231-5 (Eng. Abstr.) **(Heb)**

ORGANIC MENTAL DISORDERS, SUBSTANCE-INDUCED

Akinesia, tardive dysmentia, and frontal lobe disorder in schizophrenia. Goldberg E. **Schizophr Bull** 1985;11(2):255-63

Tardive dysmentia : further comments. Jones BD. **Schizophr Bull** 1985; 11(2):187-9

OXAZEPAM

Protein binding of oxazepam and its glucuronide conjugates to human albumin. Boudinot FD, et al. **Biochem Pharmacol** 1985 Jun 15; 34(12):2115-21

Self-reports of anxiety level and EEG changes after a single dose of benzodiazepines. Double-blind comparison of two forms of oxazepam. Ansseau M, et al. **Neuropsychobiology** 1984;12(4):255-9

PARASYMPATHOMIMETICS

The mechanism by which adenosine and cholinergic agents reduce contractility in rat myocardium. Correlation with cyclic adenosine monophosphate and receptor densities. Linden J, et al. **Circ Res** 1985 May;56(5):728-35

Comparative inhibitory effects of pirenzepine and atropine on cholinergic stimulation of exocrine and endocrine rat pancreas. Otsuki M, et al. **Gastroenterology** 1985 Aug;89(2):408-14

Cholinomimetic drug RS 86, REM sleep, and depression [letter] Berger M, et al. **Lancet** 1985 Jun 15;1(8442):1385-6

Allosteric interactions between muscarinic agonist binding sites and effector sites demonstrated by the use of bisquaternary pyridinium oximes. Kloog Y, et al. **Life Sci** 1985 Jun 3;36(22):2127-36

Cholinergic stimulation of pancreatic amylase release and muscarinic receptors: effect of ionophore A23187. Larose L, et al. **Life Sci** 1985 Jul 22;37(3):255-61

Food and water intake of broiler chicks as affected by intracerebroventricular injections of cholinomimetics. Denbow DM, et al. **Poult Sci** 1985 May;64(5):991-4

Effects of nicotinic an muscarinic stimulation on calcium flux and catecholamine secretion in primary cultures of adrenal medullary cells. Watanabe J. **Tokushima J Exp Med** 1984 Dec;31(3-4):79-84

[Comparative sensitivity of the m-cholinoreceptors in various sites to cholinotropic agents] Angelova LA. **Farmakol Toksikol** 1985 Mar-Apr; 48(2):115-20 **(Rus)**

PARGYLINE

The metabolic fate of pargyline in rat liver microsomes. Weli AM, et al. **Biochem Pharmacol** 1985 Jun 1;34(11):1993-8

Localization in rat brain of binding sites for parkinsonian toxin MPTP: similarities with [3H]pargyline binding to monoamine oxidase. Rainbow TC, et al. **Brain Res** 1985 Mar 25;330(2):337-42

Pharmacological treatment of attention deficit disorder, residual type (ADD,RT, 'minimal brain dysfunction,' 'hyperactivity') in adults. Wender PH, et al. **Psychopharmacol Bull** 1985;21(2):222-31

PEMOLINE

Oral pemoline kinetics in hyperactive children. Sallee F, et al. **Clin Pharmacol Ther** 1985 Jun;37(6):606-9

Pharmacological treatment of attention deficit disorder, residual type (ADD,RT, 'minimal brain dysfunction,' 'hyperactivity') in adults. Wender PH, et al. **Psychopharmacol Bull** 1985;21(2):222-31

PENTOBARBITAL

Interaction of penicillin and pentobarbital with inhibitory synaptic mechanisms in neocortex. Weiss DS, et al. **Cell Mol Neurobiol** 1984 Dec;4(4):301-17

Blood versus bone marrow pentobarbital concentrations. Winek CL, et al. **Forensic Sci Int** 1985 Jan;27(1):15-24

Comparison of triazolam and pentobarbital: performance impairment, subjective effects and abuse liability. Roache JD, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):120-33

gamma-Aminobutyric-acid- and pentobarbitone-gated chloride currents in internally perfused frog sensory neurones. Akaike N, et al. **J Physiol (Lond)** 1985 Mar;360:367-86

Effect of pentobarbital dependence on adenylate cyclase activity and calmodulin levels in rat cerebral cortex. Piascik MT, et al. **Life Sci** 1985 Jul 8;37(1):55-62

gamma-Aminobutyric acid partly mediates the pentobarbitone depression of synaptic excitation in the guinea-pig olfactory cortex in vitro. Steel L, et al. **Neurosci Lett** 1985 May 1;56(1):33-8

Barbiturate-enhanced paired-pulse depression in neonatal rats. Wilson DA, et al. **Neurosci Lett** 1985 May 14;56(2):101-6

Dose-related effects of pentobarbital on the genetic differences seen between paired, Roman high- or low-avoidance rats in a shuttle box. Driscoll P, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):435-9

Involvement of the serotonergic system in the prolongation of pentobarbital sleeping time produced by prostaglandin D2. Hollingsworth EB, et al. **Pharmacol Biochem Behav** 1985 Mar; 22(3):365-70

[Pre-synaptic inhibition and pentobarbital] Ohmura Y. **Masui** 1985 Jan; 34(1):2-8 (36 ref.) **(Jpn)**

PEPTIDES

Isolation from calf brain of a polypeptide fraction affecting aminoacylation of tRNA. Brzuszkiewicz-Żarnowska H, et al. **Acta Biochim Pol** 1984; 31(4):397-400

Corticotropin-releasing factor, sauvagine, and urotensin I: effects on blood flow. Lenz HJ, et al. **Am J Physiol** 1985 Jul;249(1 Pt 2):R85-90

Synthesis of side chain-protected amino acid phenylthiohydantoins and their use in quantitative solid-phase Edman degradation. Steiman DM, et al. **Anal Biochem** 1985 Feb 15;145(1):91-5

LHRH-like substance in the rat testis. Arimura A, et al. **Ann NY Acad Sci** 1984;438:390-3

Beta-endorphin, Met-enkephalin, and calcitonin in human semen: evidence for a possible role in human sperm motility. Fraioli F, et al. **Ann NY Acad Sci** 1984;438:365-70

Studies on the identification of a LHRH-like peptide in the rat testis. Hedger MP, et al. **Ann NY Acad Sci** 1984;438:371-81

GnRH-like factors in the rat testis and human seminal plasma. Swerdloff RS, et al. **Ann NY Acad Sci** 1984;438:382-9

Vascular, plasma membrane aminopeptidase M. Metabolism of vasoactive peptides. Palmieri FE, et al. **Biochem Pharmacol** 1985 Jul 1; 34(13):2309-17

Poly(DL-proline), a synthetic polypeptide behaving as an ion channel across bilayer membranes. De Santis P, et al. **Biophys Chem** 1985 Mar; 21(3-4):211-5

Peptide homologs, isosteres, and isomers: a general approach to structure-activity relationships. Goodman M. **Biopolymers** 1985 Jan;

24(1):137-55

Substance K excites dopaminergic and non-dopaminergic neurons in rat substantia nigra. Innis RB, et al. **Brain Res** 1985 Jun 3;335(2):381-3

Vasoactive intestinal peptide and PHI stimulate somatostatin release from rat cerebral cortical and diencephalic cells in dispersed cell culture. Tapia-Arancibia L, et al. **Brain Res** 1985 Jun 10;336(1):67-72

Proopiomelanocortin peptide immunocytochemistry in rhesus monkey brain. Khachaturian H, et al. **Brain Res Bull** 1984 Dec; 13(6):785-800

Localization of somatostatin-, bombesin-, and serotonin-like immunoreactivity in the lung of the fetal rhesus monkey. Dayer AM, et al. **Cell Tissue Res** 1985;239(3):621-5

Studies on peptides. CXXIII. Preparations of nine peptide fragments for the synthesis of human corticotropin releasing factor (hCRF). Fujii N, et al. **Chem Pharm Bull (Tokyo)** 1984 Dec;32(12):4786-96

Electrophysiological studies of peptide actions on the excitability of cultured nerve and pituitary cells. Barker JL, et al. **Clin Exp Hypertens** [A] 1984;6(10-11):1701-16 (32 ref.)

Proximal tubular hydrolysis and transport of small peptides. Carone FA, et al. **Contrib Nephrol** 1984;42:1-9

Absence of effect of the peptide PHI-27 on LH release in vitro. Miyake A, et al. **Endocrinol Jpn** 1984 Dec;31(6):821-4

Mouse salivary glands secrete a glucagon-degrading enzyme, not glucagon. Baldissera FG, et al. **Endocrinology** 1985 Jul;117(1):84-7

Selective regulation of carboxypeptidase peptide hormone-processing enzyme during enkephalin biosynthesis in cultured bovine adrenomedullary chromaffin cells. Hook VY, et al. **J Biol Chem** 1985 May 25;260(10):5991-7

Multiple forms of somatostatin-like immunoreactivity in the hypothalamus and amygdala of the rat: selective localization of somatostatin-28 in the median eminence. Pierotti AR, et al. **J Endocrinol** 1985 Jun; 105(3):383-9

Inhibition of sodium transport in frog skin and iodination of tyrosine in vitro by a peptide of renal origin. Fregly MJ, et al. **Klin Wochenschr** 1985;63 Suppl 3:102-6

Effects of bombesin on behavior. Cowan A, et al. **Life Sci** 1985 Jul 15; 37(2):135-45

Effect of bombesin on feeding behavior. Gibbs J. **Life Sci** 1985 Jul 15; 37(2):147-53

Bombesin evoked acetylcholine release from the guinea pig antrum Kantoh M, et al. **Life Sci** 1985 Jun 24;36(25):2445-52

Centrally-mediated bombesin effects on gastrointestinal motility. Porreca F, et al. **Life Sci** 1985 Jul 15;37(2):125-34

Central nervous system action of bombesin to inhibit gastric acid secretion. Tache Y, et al. **Life Sci** 1985 Jul 15;37(2):115-23 (43 ref.)

Characterization of a high molecular weight polypeptide from spinal cord with (Leu) enkephalin-immunoreactivity. Wahlström A, et al. **Neuropeptides** 1985 Feb;5(4-6):509-12

Cholecystokinin and bombesin suppress operant responding for food reward. Babcock AM, et al. **Pharmacol Biochem Behav** 1985 May; 22(5):893-5

Biochemistry of peptide-secreting neurons. White JD, et al. **Physiol Rev** 1985 Jul;65(3):553-606 (313 ref.)

Cerebrospinal fluid cholecystokinin, bombesin and somatostatin in schizophrenia and normals. Gerner RH, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(1):73-82

Physiological neuroendocrinology of peptides, steroids and other hormones in cerebrospinal fluid. Kee DB Jr, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(1):55-72 (131 ref.)

Distribution and vasomotor effects of peptide HI (PHI) in feline cerebral blood vessels in vitro and in situ. Edvinsson L, et al. **Regul Pept** 1985 Apr;10(4):345-56

Bombesin, neurotensin and pro-gamma-melanotropin immunoreactants in human milk. Ekman R, et al. **Regul Pept** 1985 Mar; 10(2-3):99-105

ACTH-releasing activity of urotensin I and ovine CRF: interactions with arginine vasotocin, isotocin and arginine vasopressin. Fryer J, et al. **Regul Pept** 1985 May;11(1):11-5

Effects of secretagogues on membrane potential and input resistance of pancreatic acinar cells of sheep. Katoh K, et al. **Res Vet Sci** 1985 Mar; 38(2):250-1

Effects of somatostatin-14 and somatostatin-28 on plasma hormonal and gastric secretory responses to cephalic and gastrointestinal stimulation in man. Konturek SJ, et al. **Scand J Gastroenterol** 1985 Jan; 20(1):31-8

[Effect of peptides on thermoregulation] He ZA. **Sheng Li Ko Hsueh Chin Chan** 1985 Jan;16(1):36-40 (33 ref.) **(Chi)**

[Stress and the endogenous opioid system. II. Stress, stress models and endogenous opioid peptides] Nieber K, et al. **Z Gesamte Inn Med** 1985 Feb 1;40(3):61-5 (Eng. Abstr.) **(Ger)**

PERSONALITY DISORDERS

Axis II personality disorders: diagnostic and treatment issues. Widiger TA, et al. **Hosp Community Psychiatry** 1985 Jun;36(6):619-27

Neuroticism and personality disorder in depression. Davidson J, et al. **J Affective Disord** 1985 Mar-Apr;8(2):177-82

PHENCYCLIDINE

Phencyclidine-induced inhibition of rat prolactin secretion: increased portal blood dopamine. Meltzer HY, et al. **Eur J Pharmacol** 1985 Mar 26;110(1):143-6

Acute and chronic phencyclidine administration changes serotonin receptors in rat brain. Nabeshima T, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):129-30

Hemoperfusion of phencyclidine in the dog. Allen WR, et al. **Int J Artif Organs** 1985 Mar;8(2):101-4

Comparison of chlorpromazine, haloperidol and pimozide in the treatment of phencyclidine psychosis: DA-2 receptor specificity. Giannini AJ, et al. **J Toxicol Clin Toxicol** 1984-85;22(6):573-9

Local anesthetic properties of opioids and phencyclidines: interaction with the voltage-dependent, batrachotoxin binding site in sodium channels. Creveling CR, et al. **Neuropeptides** 1985 Feb;5(4-6):253-6

Quantitative electrocortical changes in the rat induced by phencyclidine and other stimulants. Neal H, et al. **Neuropharmacology** 1985 Apr; 24(4):317-23

Effects of phencyclidine (PCP)-like drugs on turning behavior, 3H-dopamine uptake, and 3H-PCP binding. Johnson KM, et al. **Pharmacol Biochem Behav** 1985 May;22(5):731-5

PHENELZINE

Formation of beta-phenylethylamine from the antidepressant, beta-phenylethylhydrazine. Dyck LE, et al. **Biochem Pharmacol** 1985 Jun 1;34(11):1925-9

Drug interactions and vasoconstrictors used in local anesthetic solutions. Yagiela JA, et al. **Oral Surg Oral Med Oral Pathol** 1985 Jun; 59(6):565-71

'Pseudo-allergy': treatment with an MAO inhibitor. Ulwelling W. **Psychosomatics** 1985 Jun;26(6):535-6

PHENETHYLAMINES

Thermodynamics of agonist and antagonist binding to the alpha 1-adrenoceptor studied using [125I]BE 2254. Adams A, et al. **Biochem Biophys Res Commun** 1985 Apr 30;128(2):816-23

Formation of beta-phenylethylamine from the antidepressant, beta-phenylethylhydrazine. Dyck LE, et al. **Biochem Pharmacol** 1985 Jun 1;34(11):1925-9

Platelet monoamine oxidase inhibition by deprenyl and tranylcypromine: implications for clinical use. Simpson GM, et al. **Biol Psychiatry** 1985 Jun;20(6):684-7

The effects of amiflamine on cerebrospinal fluid amine metabolites in the rhesus monkey. Garrick NA, et al. **Eur J Pharmacol** 1985 Mar 26; 110(1):1-9

Selective inhibition of MAO-A but not MAO-B activity increases rat pineal melatonin. Oxenkrug GF, et al. **J Neural Transm** 1985; 61(3-4):265-70

m-Octopamine: normal occurrence with p-octopamine in mammalian sympathetic nerves. Ibrahim KE, et al. **J Neurochem** 1985 Jun; 44(6):1862-7

Inhibition of locus coeruleus neuronal activity by beta-phenylethylamine. Lundberg PA, et al. **Life Sci** 1985 May 13;36(19):1889-96

Effects of clorgyline and (-)deprenyl on the deamination of normetanephrine and noradrenaline in strips and homogenates of the canine saphenous vein. Caramona MM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):396-400

Cold-restraint stress and urinary endogenous beta-phenylethylamine excretion in rats. Snoddy AM, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):497-500

Pharmacological treatment of attention deficit disorder, residual type (ADD,RT, 'minimal brain dysfunction,' 'hyperactivity') in adults. Wender PH, et al. **Psychopharmacol Bull** 1985;21(2):222-31

PHENOBARBITAL

Monoclonal antibody directed isolation and amino-terminal sequence analysis of phenobarbital induced rat liver cytochromes P-450. Friedman FK, et al. **Biochem Biophys Res Commun** 1985 Jun 28; 129(3):926-33

Comparison of kidney, lung and liver coumarin 7-hydroxylases in phenobarbital pretreated DBA/2J and C57BL/6J mice. Kaipainen P, et al. **Biochem Pharmacol** 1985 Jun 1;34(11):1987-91

Induction of cytochrome P-450 by phenobarbital is mediated at the level of transcription. Pike SF, et al. **Biochem Pharmacol** 1985 Jul 15; 34(14):2489-94

Ultrastructural and immunohistochemical studies on non-ciliated cells of the tracheal epithelium of normal, phenobarbital-treated and 3-methylcholanthrene-treated mice. Ishimura K, et al. **Cell Tissue Res** 1985;240(2):501-4

Effect of peritoneal dialysis on serum concentrations of three drugs commonly used in pediatric patients. Chow-Tung E, et al. **Dev Pharmacol Ther** 1985;8(2):85-95

Diphenylbarbituric acid: its effects on neuromuscular and spinal cord function in the cat. Zavadil AP 3d, et al. **Epilepsia** 1985 Mar-Apr; 26(2):158-66

Long-term behavioral effects of phenobarbital in suckling rats. McBride MC, et al. **Exp Neurol** 1985 Jul;89(1):59-70

Response of meiotic chromosomes of mice to phenobarbitone. Subramanyam S, et al. **Indian J Exp Biol** 1984 Dec;22(12):666-9

On the mechanism of the inactivation of the major phenobarbital-inducible isozyme of rat liver cytochrome P-450 by chloramphenicol. Halpert JR, et al. **J Biol Chem** 1985 Jul 15; 260(14):8397-403

Gene structure of a major form of phenobarbital-inducible cytochrome P-450 in rat liver. Suwa Y, et al. **J Biol Chem** 1985 Jul 5; 260(13):7980-4

Kinetics of drug action in disease states. XIII. Effect of dialyzable component(s) of uremic blood on phenobarbital concentrations in rats at onset of loss of righting reflex. Hisaoka M, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):180-3

Effect of centrally acting drugs on ethanol detoxification enzymes in distinct rat brain regions. Messiha FS. **Neurobehav Toxicol Teratol** 1985 Mar-Apr;7(2):181-4

Stereological analysis of smooth endoplasmic reticulum and peroxisome proliferation in hepatocytes from neonatal and adult mice after phenobarbital administration. Kanai K, et al. **Okajimas Folia Anat Jpn** 1984 Dec;61(5):327-35

Effects of phenytoin, phenobarbital, and valproic acid, alone and in selected combinations, on schedule-controlled behavior of rats. Picker M, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):389-93

The time course of [3H]PteGlu uptake and its incorporation into pteroylpolyglutamates in liver of phenobarbitone treated rats. Formiggini G, et al. **Pharmacol Res Commun** 1985 Feb;17(2):123-8

Biopharmaceutical investigation of rectal suppositories. Part 2(1): Pharmaceutical and biological availability of phenobarbital and phenobarbital-sodium. Minkov E, et al. **Pharmazie** 1985 Apr; 40(4):257-9

Neonatal phenobarbital imprinting of hepatic microsomal enzymes in adult rats: modulation by neonatal testosterone presence. Bagley DM, et al. **Toxicol Appl Pharmacol** 1985 Jun 30;79(2):227-35

Inducible aldehyde dehydrogenases from rat liver cytosol. Simpson VJ, et al. **Toxicol Appl Pharmacol** 1985 Jun 30;79(2):193-203

Reduction of ochratoxin A toxicity in mice treated with phenylalanine and phenobarbital. Moroi K, et al. **Toxicol Lett** 1985 Apr;25(1):1-5

Effects of rifampicin and phenobarbital on the fate of isoniazid and hydrazine in vivo in rats. Noda A, et al. **Toxicol Lett** 1985 Jun; 25(3):313-7

[Pharmacokinetics of injectable phenobarbital in the premature infant. Study of a new lyophilized form] Kossmann JC, et al. **Arch Fr Pediatr** 1985 Apr;42(4):317-20 (Eng. Abstr.) **(Fre)**

[Value of a charcoal column of our design for hemoperfusion in the treatment of experimental barbiturate poisoning] Bakula S, et al. **Pol Tyg Lek** 1985 Feb 25;40(8):217-9 (Eng. Abstr.) **(Pol)**

[Comparative study of zixoryn and phenobarbital as enzyme inducers of the liver mono-oxygenase system] Loginov AS, et al. **Biull Eksp Biol Med** 1985 Apr;99(4):437-40 (Eng. Abstr.) **(Rus)**

[Immunomorphological study of cytochrome P-450PB induction in the liver of rat embryos and pregnant females after phenobarbital administration] Popova NV, et al. **Biull Eksp Biol Med** 1985 Mar; 99(3):366-8 (Eng. Abstr.) **(Rus)**

[Nomogram for phenobarbital dosage in children (letter)] Armijo JA, et al. **An Esp Pediatr** 1985 Apr 15;22(5):418-21 **(Spa)**

PHENOTHIAZINE TRANQUILIZERS

Lipids and apolipoproteins in patients treated with major tranquilizers. Sasaki J, et al. **Clin Pharmacol Ther** 1985 Jun;37(6):684-7

Behavioral indications for phenothiazine and benzodiazepine tranquilizers in dogs. Hart BL. **J Am Vet Med Assoc** 1985 Jun 1;186(11):1192-4

[Ecto-ATPases in leukocytes and its modification by drugs] Hehl EM, et al. **Allerg Immunol (Leipz)** 1985;31(1):17-23 (Eng. Abstr.) **(Ger)**

[Biotransformation of Chlorphenethazin (Elroquil, Marophen)] Pfeifer S, et al. **Pharmazie** 1985 Jan;40(1):37-9 (Eng. Abstr.) **(Ger)**

[Clinico-humoral manifestations secondary to treatment with injectable Tisercin] Gheorghe M, et al. **Rev Med Interna [Neurol Psihiatr]** 1985 Jan-Mar;30(1):71-2 **(Rum)**

PHENOTHIAZINES

Interaction of phenothiazine drugs with human ceruloplasmin. Relation between activation of catecholamine neurotransmitter oxidation and electron donating ability of phenothiazine drugs. de Mol NJ. **Biochem Pharmacol** 1985 Aug 1;34(15):2605-9

Reciprocal effects of phenothiazines and naphthalene sulfonamides on the external ATP-dependent permeability change in Chinese hamster ovary cells. Kitagawa T, et al. **Biochim Biophys Acta** 1985 Apr 26; 815(1):25-32

Selective effects of CAPP1-calmodulin on its target proteins. Newton D, et al. **Biochim Biophys Acta** 1985 Jun 30;845(3):533-9

Cimetidine inhibition of ethmozine metabolism. Biollaz J, et al. **Clin Pharmacol Ther** 1985 Jun;37(6):665-8

Pharmacokinetics of dixyrazine: low bioavailability, improved by food intake. Liedholm H, et al. **Drug Nutr Interact** 1985;3(2):87-92

The involvement of nucleosomes in Giemsa staining of chromosomes. A new hypothesis on the banding mechanism. van Duijn P, et al. **Histochemistry** 1985;82(4):363-76

Assessment of the potential pharmacokinetic interaction between digoxin and ethmozine. MacFarland RT, et al. **J Clin Pharmacol** 1985 Mar; 25(2):138-43

A versatile and simple method for staining nervous tissue using Giemsa dye. Iñiguez C, et al. **J Neurosci Methods** 1985 Mar;13(1):77-86

Application of Azure C for the extractive spectrophotometric determination of microgram amounts of penicillin. Gowda AT, et al. **J Pharmacol Methods** 1985 Jun;13(3):275-80

[Interaction of oxygen anion radicals with eye melanins and ommochromes] Lapina VA, et al. **Dokl Akad Nauk SSSR** 1985; 280(6):1463-5 **(Rus)**

PHENOXYBENZAMINE

Influence of intracerebroventricular phenoxybenzamine on the renal action of intracerebroventricular morphine. Kook YJ, et al. **Arch Int Pharmacodyn Ther** 1985 Feb;273(2):289-98

PHENYLALANINE

Identification of peptides containing tryptophan, tyrosine, and phenylalanine using photodiode-array spectrophotometry. Yang CY, et al. **Anal Biochem** 1985 Feb 15;145(1):67-72

L-Phenylalanine and L-tyrosine catabolism by selected Streptomyces species. Pometto AL 3d, et al. **Appl Environ Microbiol** 1985 Mar; 49(3):727-9

Abilities of some tryptophan and phenylalanine derivatives to inhibit gastric acid secretion. Magous R, et al. **Biochim Biophys Acta** 1985 May 30;845(2):158-62

The effect of the intracellular sodium level on the activity of amino acid transport systems L and A in SV40 3T3 cells. Petronini PG, et al. **Biochim Biophys Acta** 1985 May 28;815(3):361-8

Clues from Xanthomonas campestris about the evolution of aromatic biosynthesis and its regulation. Whitaker RJ, et al. **J Mol Evol** 1984-85; 21(2):139-49

The effect of phenylalanine on intracellular pH and sodium activity in proximal convoluted tubule cells of the frog kidney. Messner G, et al. **Pflugers Arch** 1985 May;404(2):145-9

Reduction of ochratoxin A toxicity in mice treated with phenylalanine and phenobarbital. Moroi K, et al. **Toxicol Lett** 1985 Apr;25(1):1-5

PHENYLPROPANOLAMINE

Determination of phenylpropanolamine hydrochloride and acetaminophen in pharmaceutical preparations by Raman spectroscopy. King TH, et al. **J Pharm Sci** 1985 Apr;74(4):443-7

Effects of reserpine and adrenal demedullation on brown adipose tissue thermogenesis induced by dl-phenylpropanolamine. Wellman PJ, et al. **Res Commun Chem Pathol Pharmacol** 1985 Feb;47(2):211-20

Vascular effects of phenylpropanolamine on human nasal mucosa. Bende M, et al. **Rhinology** 1985 Mar;23(1):43-8

PHENYTOIN

Effects of ibuprofen on the disposition kinetics of phenytoin in pregnant rats. Cleveland PA, et al. **Biopharm Drug Dispos** 1985 Apr-Jun; 6(2):167-76

Audit of a monitoring service for free phenytoin. Peterson GM, et al. **Br J Clin Pharmacol** 1985 May;19(5):693-7

Effect of phenytoin on intracellular calcium and intracellular protein changes during pentylenetetrazole-induced bursting activity in snail neurons. Sugaya E, et al. **Brain Res** 1985 Feb 18;327(1-2):161-8

A theoretical and an in vitro experimental model for estimation of drug transfer through the human placenta. Mor L, et al. **Contrib Gynecol Obstet** 1985;13:155-7

Phenytoin clearance by continuous ambulatory peritoneal dialysis. Hays DP, et al. **Drug Intell Clin Pharm** 1985 Jun;19(6):429-31

Effects of phenytoin administration on vestibular function in the rat. Mameli O, et al. **Epilepsia** 1985 May-Jun;26(3):262-7

The effects of phenytoin on serum and organ concentrations of zinc and copper in cat. Palm R, et al. **Epilepsia** 1985 Mar-Apr;26(2):184-8

A rapid method for separation and estimation of free phenytoin in serum. Ahmad SN, et al. **Indian J Exp Biol** 1984 Nov;22(11):605-7

Phenytoin bioavailability assessed by steady state serum concentrations. Halkin H, et al. **Isr J Med Sci** 1985 Apr;21(4):327-30

Phenytoin pharmacokinetics in therapeutic plasmapheresis. Nasca TJ, et al. **J Clin Pharmacol** 1985 May-Jun;25(4):302-4

The use of a monosaccharide linkage group in a heterologous solid-phase enzyme immunoassay for phenytoin. Hinds JA, et al. **J Immunol Methods** 1985 Jun 25;80(2):239-53

Expanding physician duties and patients rights in wrongful life: Harbeson

v. Parke-Davis, Inc. Skolnick M. **Med Law** 1985;4(3):283-98

Mutagenic potential of anticonvulsant diphyenylhydantoin (DPH) on human lymphocytes in vitro. Maurya AK, et al. **Methods Find Exp Clin Pharmacol** 1985 Mar;7(3):109-12

Preparation of a phenytoin beta-cyclodextrin complex and evaluation of a suspension and a tablet dosage form prepared from the complex. Hegde RP, et al. **Pharm Acta Helv** 1985;60(2):53-7

Effects of phenytoin, phenobarbital, and valproic acid, alone and in selected combinations, on schedule-controlled behavior of rats. Picker M, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):389-93

Phenytoin and trimethadione: pharmacokinetics, embryotoxicity, and maternal toxicity. Khera KS. **Prog Clin Biol Res** 1985;163C:317-22

Phenytoin teratogenicity and effects on embryonic and maternal folate metabolism. Hansen DK, et al. **Teratology** 1985 Jun;31(3):363-71

The water, DNA, collagen and noncollagen protein contents in embryos after maternal administration of a teratogenic dose of phenytoin. Hicks HE, et al. **Toxicol Lett** 1985 Apr;25(1):41-6

[Study on phenytoin-selective electrode] Yao SZ, et al. **Yao Hsueh Hsueh Pao** 1984 Jun;19(6):455-60 (Eng. Abstr.) **(Chi)**

[Effects of diphenylhydantoin on thyroid function] Giroud M, et al. **Therapie** 1985 Mar-Apr;40(2):119-22 (Eng. Abstr.) **(Fre)**

[Experimental study of the effects of diphenylhydantoins and estrogens in rats. I. Microbiological aspects of changes in the gingival flora of rats treated with diphenylhydantoins] Bascones A, et al. **Rev Esp Estomatol** 1984 May-Jun;32(3):147-54 **(Spa)**

[Clinical pharmacology of carbamazepine--a comparison with phenytoin] Bertilsson L, et al. **Lakartidningen** 1985 Apr 10;82(15):1355-60 **(Swe)**

PHOBIC DISORDERS

Agoraphobia. Horn TL. **Am Fam Physician** 1985 Jul;32(1):165-73

Combined pharmacological and behavioral treatment for agoraphobia. Telch MJ, et al. **Behav Res Ther** 1985;23(3):325-35

Dysmorphophobia [letter] Jenike MA. **Br J Psychiatry** 1985 Mar; 146:326

Agoraphobia. Pyke JM, et al. **Can Nurse** 1985 Jun;81(6):18-21

Modification of disease phobia using a multifaceted exposure program. Tearnan BH, et al. **J Behav Ther Exp Psychiatry** 1985 Mar; 16(1):57-61

Catecholamine secretion as a function of perceived coping self-efficacy. Bandura A, et al. **J Consult Clin Psychol** 1985 Jun;53(3):406-14

Psychophysiological outcome of behavioral and pharmacological treatments of agoraphobia. Michelson L, et al. **J Consult Clin Psychol** 1985 Apr;53(2):229-36

[Agoraphobia] Pyke JM, et al. **Infirm Can** 1985 Jun;27(6):24-7 **(Fre)**

PHYSOSTIGMINE

Antagonism of physostigmine induced lethality by a combination of scopolamine and methscopolamine. Janowsky DS, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 Feb;56(2):154-7

Characteristics of yawning behavior induced by apomorphine, physostigmine and pilocarpine. Ushijima I, et al. **Arch Int Pharmacodyn Ther** 1985 Feb;273(2):196-201

Physostigmine reverses memory deficits produced by pretraining electrical stimulation of the dorsal hippocampus in mice. Micheau J, et al. **Behav Brain Res** 1985 Apr;15(2):75-81

Physostigmine effects on serotonin uptake in human blood platelets. Rausch JL, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):91-6

Determination of physostigmine in plasma and brain by HPLC. Somani SM, et al. **J Anal Toxicol** 1985 Mar-Apr;9(2):71-5

Plasma physostigmine concentrations after oral administration [letter] Sharpless NS, et al. **Lancet** 1985 Jun 15;1(8442):1397-8

Inhibitory effects of dopamine and isoprenaline on antral motor activity stimulated by acetylcholine or physostigmine in vitro. Ulvestad A, et al. **Scand J Gastroenterol** 1985 Mar;20(2):243-6

[The acute toxicity of eserine, VX and paraoxon for the establishment of a mathematical model for extrapolation to humans] Leblic C, et al. **Arch Belg** 1984;Suppl:226-42 (Eng. Abstr.) **(Fre)**

[Stabilization of physostigmine salicylate injection solutions] Trose D, et al. **Pharmazie** 1985 Feb;40(2):124-6 (Eng. Abstr.) **(Ger)**

PILOCARPINE

Characteristics of yawning behavior induced by apomorphine, physostigmine and pilocarpine. Ushijima I, et al. **Arch Int Pharmacodyn Ther** 1985 Feb;273(2):196-201

Prevention of intraocular pressure elevation following neodymium-YAG laser posterior capsulotomy. Richter CU, et al. **Arch Ophthalmol** 1985 Jul;103(7):912-5

Comparison of the effects of chronic administration of ciclazindol and desipramine on pupillary responses to tyramine, methoxamine and pilocarpine in healthy volunteers. Kerr FA, et al. **Br J Clin Pharmacol** 1985 May;19(5):639-47

[The stability of pilocarpine hydrochloride in eyedrops] Porst H, et al. **Pharmazie** 1985 Jan;40(1):23-9 (Eng. Abstr.) **(Ger)**

PITUITARY HORMONE RELEASING HORMONES

Gonadotropin releasing hormone stimulates the formation of inositol phosphates in rat anterior pituitary tissue. Schrey MP. **Biochem J** 1985 Mar 1;226(2):563-9

Modulation of lordosis behaviour in the female rat by corticotropin releasing factor, beta-endorphin and gonadotropin releasing hormone in the mesencephalic central gray. Sirinathsinghji DJ. **Brain Res** 1985 Jun 10;336(1):45-55

Mechanisms of gonadotropin-releasing hormone and prostaglandin action on luteal cells. Leung PC. **Can J Physiol Pharmacol** 1985 Mar; 63(3):249-56 (79 ref.)

Increased gonadotropin-releasing hormone pulse frequency associated with estrogen-induced luteinizing hormone surges in ovariectomized ewes. Clarke IJ, et al. **Endocrinology** 1985 Jun;116(6):2376-83

Longitudinal study of the surge of gonadotropins induced by exogenous hormones in prepuberal gilts. Fleming MW, et al. **Endocrinology** 1985 May;116(5):1893-8

The frequency of gonadotropin-releasing hormone stimulation determines the number of pituitary gonadotropin-releasing hormone receptors. Katt JA, et al. **Endocrinology** 1985 May;116(5):2113-5

Release of luteinizing hormone and follicle-stimulating hormone from pituitaries of lactating rats by gonadotropin-releasing hormone and high potassium concentration. Smith MS. **Endocrinology** 1985 May; 116(5):1826-34

FSH and LH response to testosterone and gonadotropin-releasing hormone in aging male rats. Sartin JL, et al. **Exp Aging Res** 1984 Winter; 10(4):183-7

Influence of the frequency of gonadotropin-releasing hormone (GnRH) administration on ovulatory responses in women with anovulation. Bringer J, et al. **Fertil Steril** 1985 Jul;44(1):42-8

Structure-activity relationships of mammalian, chicken, and salmon gonadotropin releasing hormones in vivo in goldfish. Peter RE, et al. **Gen Comp Endocrinol** 1985 May;58(2):231-42

Successful pregnancy following ovulation induction with pulsatile GnRH. O'Herlihy C, et al. **Ir Med J** 1985 May;78(5):133-4, 136

Hypothalamic gonadotrophin-releasing hormone and pituitary and plasma FSH and prolactin during photostimulation and photorefractoriness in intact and thyroidectomized starlings (Sturnus vulgaris). Dawson A, et al. **J Endocrinol** 1985 Apr;105(1):71-7

Diacylglycerols and protein kinase C. Potential amplifying mechanism for Ca2+-mediated gonadotropin-releasing hormone-stimulated luteinizing hormone release. Harris CE, et al. **Mol Pharmacol** 1985 May; 27(5):532-6

Differential suppression of follicle-stimulating hormone and luteinizing hormone secretion in vivo by a gonadotropin-releasing hormone antagonist. Grady RR, et al. **Neuroendocrinology** 1985 Mar; 40(3):246-52

[Pulsatile administration of gonadoliberin by subcutaneous route in the induction of ovulation (letter)] Fenichel P, et al. **Presse Med** 1985 Apr 13;14(15):846 **(Fre)**

[The effect of blood serum on GnRH-loaded multilayer liposomes: proof of a correlation between their size and the inclusion stability of the peptide hormones] Schäfer H, et al. **Pharmazie** 1985 Feb;40(2):131-2 **(Ger)**

PITUITARY HORMONES, ANTERIOR

Ketanserin without effects on basal anterior pituitary hormone secretion in healthy subjects. Gordin A, et al. **J Endocrinol Invest** 1985 Feb; 8(1):73-5

Idiopathic premature ovarian failure. A clinical and biochemical study. Naidoo C, et al. **S Afr Med J** 1985 Jul 20;68(2):91-4

PROGESTERONE

Progesterone stimulates sexual behaviour in female rats by increasing 5-HT activity on 5-HT2 receptors. Wilson CA, et al. **Brain Res** 1985 May 6;333(2):223-9

In vitro and in vivo antagonistic regulation by estradiol and progesterone of the rat pituitary domperidone binding sites: correlation with ovarian steroid regulation of the dopaminergic inhibition of prolactin secretion in vitro. Bression D, et al. **Endocrinology** 1985 May;116(5):1905-11

Phorbol ester regulation of rat granulosa cell prostaglandin and progesterone accumulation. Kawai Y, et al. **Endocrinology** 1985 Jun; 116(6):2320-6

Relation of circulating estradiol and progesterone to gonadotropin secretion and estrous cyclicity in aging female rats. Lu JK, et al. **Endocrinology** 1985 May;116(5):1953-9

Exogenous progesterone for luteal support following gonadotropin-releasing hormone ovulation induction: case report. Berger NG, et al. **Fertil Steril** 1985 Jul;44(1):133-5

Hormonal influence on the response of the uterus of the Brazilian marsupial Didelphis albiventris to adrenergic drugs. Rocha LR, et al. **Gen Comp Endocrinol** 1985 May;58(2):179-85

Progesterone-induced LHRH release in vitro is an estrogen--as well as Ca++- and calmodulin-dependent secretory process. Drouva SV, et al. **Neuroendocrinology** 1985 Apr;40(4):325-31

Effects of progesterone on hypothalamic and plasma LHRH. Peduto JC, et al. **Neuroendocrinology** 1985 Mar;40(3):238-45

PROLACTIN

Age-related changes in prolactin and growth hormone release from pituitary glands in vitro. Hall TR, et al. **Acta Endocrinol (Copenh)** 1985 Apr;108(4):479-84

Plasma prolactin in the rat during suckling without prior separation from pups. Mattheij JA, et al. **Acta Endocrinol (Copenh)** 1985 Apr; 108(4):468-74

Temporary increase in the circulating prolactin levels during and after consecutive administration of bromocriptine-mesilate (CB-154) in female mice. Mori T, et al. **Acta Endocrinol (Copenh)** 1985 Jun; 109(2):208-13

Neuro-endocrine effects of isotheoline. Zhelyazkov D, et al. **Acta Physiol Pharmacol Bulg** 1984;10(4):53-8

Serum concentrations of thyroxine, 3,5,3'-triiodothyronine, thyrotropin, and prolactin in dogs before and after thyrotropin-releasing hormone administration. Kaufman J, et al. **Am J Vet Res** 1985 Feb; 46(2):486-92

Dopamine D2 receptors modulate neurotransmitter-regulated calcium ion gates. Memo M, et al. **Ann Ist Super Sanita** 1984;20(1):5-10

Effect of prolactin and bromocriptine administration on testicular metabolism in albino rats. Dhananjaya Reddy Y, et al. **Arch Int Physiol Biochim** 1985 May;93(1):19-23

Dose-dependent inhibition of the preovulatory surges of gonadotropins and prolactin by the antiestrogen CI-628: possible sites of action. De Paolo LV. **Biol Reprod** 1985 May;32(4):745-52

The proestrous surge of prolactin enhances sexual receptivity in the rat. Witcher JA, et al. **Biol Reprod** 1985 May;32(4):834-9

Effect of feed and water deprivation or force-feeding on plasma prolactin concentration in turkey hens. Zadworny D, et al. **Biol Reprod** 1985 Mar;32(2):241-7

Intolerance of bromocriptine: is metergoline a satisfactory alternative? Casson IF, et al. **Br Med J [Clin Res]** 1985 Jun 15; 290(6484):1783-4

Effects of prostaglandin F2 alpha on prolactin secretion in the fowl. Hall TR, et al. **Br Poult Sci** 1985 Apr;26(2):239-45

The effect of long-term diethylstilbestrol treatment or hyperprolactinemia on the response of the tuberoinfundibular dopamine neurons to elevated prolactin. Morgan WW, et al. **Brain Res** 1985 Jun 3;335(2):330-3

Evaluation of the central dopaminergic activity in gestational hyperprolactinaemia by means of the electroretinographic technique. De Luca Brunori I, et al. **Clin Exp Obstet Gynecol** 1985; 12(1-2):13-5

p-Tyramine, a natural amine, inhibits prolactin release in vivo. Becú-Villalobos D, et al. **Endocrinology** 1985 May;116(5):2044-8

In vitro and in vivo antagonistic regulation by estradiol and progesterone of the rat pituitary domperidone binding sites: correlation with ovarian steroid regulation of the dopaminergic inhibition of prolactin secretion in vitro. Bression D, et al. **Endocrinology** 1985 May;116(5):1905-11

D-Trp-6-luteinizing hormone-releasing hormone inhibits hyperprolactinemia in female rats. Debeljuk L, et al. **Endocrinology** 1985 Jun;116(6):2227-31

5-Hydroxyeicosatetraenoic acid increases prolactin release from rat anterior pituitary cells. Koike K, et al. **Endocrinology** 1985 May; 116(5):1813-7

Studies on the effects of catecholestrogens on prolactin secretion by cultured normal rat anterior pituitary cells. Lamberts SW, et al. **Endocrinology** 1985 Jun;116(6):2631-6

Prolactin metabolic clearance and resistance to dopaminergic suppression in acute uremia. McKenna TM, et al. **Endocrinology** 1985 May; 116(5):2003-7

Rapid effects of hyperprolactinemia on basal prolactin secretion and dopamine turnover in the medial and lateral median eminence. Selmanoff M. **Endocrinology** 1985 May;116(5):1943-52

Increased hepatic and reduced prostatic prolactin (PRL) binding in iron deficiency and during neuroleptic treatment: correlation with changes in serum PRL and testosterone. Barkey RJ, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):193-200

Phencyclidine-induced inhibition of rat prolactin secretion: increased portal blood dopamine. Meltzer HY, et al. **Eur J Pharmacol** 1985 Mar 26;110(1):143-6

Inhibition by antiserum to vasoactive intestinal polypeptide (VIP) of prolactin secretion induced by serotonin in the rat. Ohta H, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):409-12

Number of dopamine neurons predicts prolactin levels in two inbred mouse strains. Sved AF, et al. **Experientia** 1985 May 15;41(5):644-6

Pergolide mesylate inhibits exercise-induced prolactin release in man. De Meirleir K, et al. **Fertil Steril** 1985 Apr;43(4):628-31

Hyperprolactinaemia and testosterone production. Observations in 2 men on long-term dialysis. Stegmayr B, et al. **Horm Res** 1985; 21(4):224-8

Chronic treatment with 2-alpha-bromocriptine in women with the hyperprolactinemic syndrome. Eshel A, et al. **Int J Fertil** 1984; 29(4):247-53

Effects of induced hypoprolactinemia on testicular function during gonadal maturation in the rat. Suescun MO, et al. **J Androl** 1985 Mar-Apr;6(2):77-82

Levels of dopamine and thyrotrophin-releasing hormone in hypophysial stalk blood during an oestrogen-stimulated surge of prolactin in the ovariectomized rat. de Greef WJ, et al. **J Endocrinol** 1985 Apr; 105(1):107-12

Possible role of prolactin in the inhibitory effect of testosterone on the hypothalamic-pituitary-testicular axis in the rat. Tresguerres JA, et al. **J Endocrinol** 1985 Jun;105(3):423-7

The putative dopamine autoreceptor agonist B-HT 920 decreases nigral dopamine cell firing rate and prolactin release in rat. Eriksson E, et al. **Life Sci** 1985 May 13;36(19):1819-27

The mechanism of action of cyproheptadine on prolactin release by cultured anterior pituitary cells. Lamberts SW, et al. **Life Sci** 1985 Jun 10;36(23):2257-62

Adrenalectomy does not prevent the hyperprolactinemic, induced sexual behavior deficits in CDF male rats. Shrenker P, et al. **Life Sci** 1985 May 13;36(19):1881-8

Calcium mobilization potentiates prolactin release induced by protein kinase C activators. Koike K, et al. **Mol Cell Endocrinol** 1985 May; 40(2-3):137-43

Hypoprolactinemia induced by hypophysectomy and long-term bromocriptine treatment decreases tuberoinfundibular dopaminergic neuronal activity and the responsiveness of these neurons to prolactin. Demarest KT, et al. **Neuroendocrinology** 1985 May;40(5):369-76

Dopamine-induced physical barrier to inhibit prolactin release in mammotrophs disappears during resumption of prolactin secretion. Reifel CW, et al. **Neuroendocrinology** 1985 May;40(5):438-43

Cimetidine-induced prolactin release: possible involvement of the GABA-ergic system. Sibilia V, et al. **Neuroendocrinology** 1985 Mar; 40(3):189-92

gamma-Aminobutyric acid decreases levels of messenger ribonucleic acid encoding prolactin in the rat pituitary. Loeffler JP, et al. **Neurosci Lett** 1985 Jan 7;53(1):121-5

Serum and cerebrospinal fluid prolactin patterns during neuroleptic treatment in schizophrenic patients. Rimón R, et al. **Pharmacopsychiatry** 1985 May;18(3):252-4

Cyproheptadine stimulated prolactin release in the young turkey (Meleagris gallopavo). Fehrer SC, et al. **Poult Sci** 1985 May; 64(5):1038-40

Central inhibitory action of TRH on prolactin secretion in the rat. Ohta H, et al. **Proc Soc Exp Biol Med** 1985 May;179(1):9-12

Dose-dependent growth hormone, prolactin and cortisol stimulation after i.v. administration of desimipramine in human subjects. Laakmann G, et al. **Psychoneuroendocrinology** 1985;10(1):83-93

Effect of benztropine on the diurnal prolactin responses to haloperidol. Nathan RS, et al. **Psychoneuroendocrinology** 1985;10(1):71-6

Behavior therapy, pimozide treatment and prolactin secretion in anorexia nervosa. Weizman A, et al. **Psychother Psychosom** 1985;43(3):136-40

[Activity of clobazam on plasma prolactin and gonadotropins after administration of sulpiride in the male rat] Valli M, et al. **Ann Endocrinol (Paris)** 1984;45(6):409-11 (Eng. Abstr.) **(Fre)**

[The mechanism of induction of ovulation by bromocriptine in euprolactinemic anovulation--the role of occult hyperprolactinemia in anovulation] Mori H, et al. **Nippon Naibunpi Gakkai Zasshi** 1985 Jan 20;61(1):38-47 (Eng. Abstr.) **(Jpn)**

[The effects of bromocriptine on anovulatory patients with high LH and euprolactinemia] Mori H, et al. **Nippon Naibunpi Gakkai Zasshi** 1985 Jan 20;61(1):48-55 (Eng. Abstr.) **(Jpn)**

[Specific proteases which degrade prolactin in the mammary glands; subcellular localization and inhibitory analysis] Marinchenko GV. **Biokhimiia** 1985 Feb;50(2):200-10 (Eng. Abstr.) **(Rus)**

[Lactation and re-induction of lactation] Vargas W. **GEN** 1983 Jan-Jun; 37(1-2):16-28 **(Spa)**

PROMETHAZINE

Effects of some motion sickness suppressants on static and dynamic tracking performance. Schroeder DJ, et al. **Aviat Space Environ Med** 1985 Apr;56(4):344-50

Changes in the disposition of promethazine during multiple dosing in the rabbit. Taylor G, et al. **J Pharm Pharmacol** 1985 Apr;37(4):243-7

[Attempted suicide with barbiturate after glue sniffing] Sami HO, et al. **Orv Hetil** 1985 Mar 31;126(13):781-3 (Eng. Abstr.) **(Hun)**

PROPANEDIOLS

Propylene glycol-induced heparin resistance during nitroglycerin infusion. Col J, et al. **Am Heart J** 1985 Jul;110(1 Pt 1):171-3

Solubilization by cosolvents I: organic solutes in propylene glycol-water mixtures. Yalkowsky SH, et al. **J Pharm Sci** 1985 Apr;74(4):416-21

PROPERICIAZINE

Measurement of propericiazine in plasma by capillary gas chromatography and selected ion monitoring detection. De Leenheer AP, et al. **Biomed Mass Spectrom** 1985 Jan;12(1):25-9

PROPRANOLOL

Effect of propranolol on post-traumatic hypophosphataemia and catecholamine secretion. Lovén L, et al. **Acta Chir Scand** 1985; 151(3):201-4

Perturbations of sarcolemmal and microsomal enzymes by amphiphilic lipids and drugs. Weglicki WB, et al. **Adv Myocardiol** 1985;6:127-36

Effects of cardioselective and nonselective beta-adrenergic blockade on the performance of highly trained runners. Anderson RL, et al. **Am J Cardiol** 1985 Apr 26;55(10):149D-154D

Effect of selective and nonselective beta-adrenoceptor blockade on thermoregulation during prolonged exercise in heat. Gordon NF. **Am J Cardiol** 1985 Apr 26;55(10):74D-78D

Cardiovascular and pharmacokinetic consequences of combined administration of verapamil and propranolol in dogs. Hamann SR, et al. **Am J Cardiol** 1985 Jul 1;56(1):147-56

Effects of intravenous infusion of esmolol and propranolol on biventricular performance at rest and during exercise as assessed by quantitative radionuclide angiography. Iskandrian AS, et al. **Am J Cardiol** 1985 May 1;55(11):1287-92

Beta blockade in the compensation for bed-rest cardiovascular deconditioning: physiologic and pharmacologic observations. Sandler H, et al. **Am J Cardiol** 1985 Apr 26;55(10):114D-119D

Exercise training during long-term beta-blockade treatment in healthy subjects. Savin WM, et al. **Am J Cardiol** 1985 Apr 26; 55(10):101D-109D

Cardiorespiratory alterations consequent to endurance exercise training during chronic beta-adrenergic blockade with atenolol and propranolol. Wilmore JH, et al. **Am J Cardiol** 1985 Apr 26;55(10):142D-148D

Acute response to submaximal and maximal exercise consequent to beta-adrenergic blockade: implications for the prescription of exercise. Wilmore JH, et al. **Am J Cardiol** 1985 Apr 26;55(10):135D-141D

Effects of aspirin and propranolol alone and in combination on hemostatic determinants in the healthy cat. Allen DG, et al. **Am J Vet Res** 1985 Mar;46(3):660-3

Effect of propranolol on human spermatozoal in vitro hamster ova penetration. Chan SY, et al. **Arch Androl** 1984;12 Suppl:79-82

Renin response to captopril in conscious dogs pretreated with indomethacin or propranolol. Kamijo T, et al. **Arch Int Pharmacodyn Ther** 1985 Mar;274(1):56-64

Modification of propranolol binding to alpha-1-acid glycoprotein by serum albumin. Chauvelot-Moachon L, et al. **Biochem Pharmacol** 1985 May 1;34(9):1591-4

Reduced hepatic uptake of propranolol in rats with acute renal failure. Hori R, et al. **Biochem Pharmacol** 1985 Aug 1;34(15):2679-83

Adrenergic ligand binding in human serum. Sager G, et al. **Biochem Pharmacol** 1985 Aug 1;34(15):2812-5

Semi-empirical conformational analysis of propranolol interacting with dipalmitoylphosphatidylcholine. Brasseur R, et al. **Biochim Biophys Acta** 1985 May 28;815(3):341-50

Penbutolol and propranolol: a comparison of their effects on antipyrine clearance in man. Bax ND, et al. **Br J Clin Pharmacol** 1985 May; 19(5):593-6

A comparison of the effects of lorazepam with those of propranolol on experimentally-induced anxiety and performance. File SE, et al. **Br J Clin Pharmacol** 1985 Apr;19(4):445-51

The effects of propranolol and digoxin on the acute vascular responses to frusemide in normal man. Johnston GD, et al. **Br J Clin Pharmacol** 1985 Apr;19(4):417-21

Pre-dosing plasma concentrations and beta-adrenoceptor blocking effects during repeated once daily dosing with 160 mg sustained-release propranolol (Inderal LA) and 16/260 oxprenolol Oros to healthy volunteers. Moppert J, et al. **Br J Clin Pharmacol** 1985; 19 Suppl 2:197S-201S

Comparative effects of adimolol, labetalol and propranolol on heart rate and blood pressure in man. Riddell JG, et al. **Br J Clin Pharmacol** 1985 Apr;19(4):405-10

Ethnic differences in human lymphocytic cyclic AMP production after isoprenaline stimulation and propranolol blockade. Venter CP, et al. **Br J Clin Pharmacol** 1985 Feb;19(2):187-90

Enhancement of the antiaggregatory activity of prostacyclin by propranolol in human platelets. Callahan KS, et al. **Circulation** 1985 Jun;71(6):1237-46

Propranolol: pooled Michaelis-Menten parameters and the effect of input rate on bioavailability. Wagner JG. **Clin Pharmacol Ther** 1985 May; 37(5):481-7

Quantitative account of propranolol metabolism in urine of normal man. Walle T, et al. **Drug Metab Dispos** 1985 Mar-Apr;13(2):204-9

Comparative beta-adrenoceptor blocking effect and pharmacokinetics of bucindolol and propranolol in man. Maury M, et al. **Eur J Clin Pharmacol** 1985;27(6):649-56

Effects of propranolol during pregnancy and development of rats. II. Adverse effects on development. Schoenfeld N, et al. **Eur J Pediatr** 1985 Jan;143(3):194-5

The contribution of vasopressin and angiotensin to the maintenance of blood pressure after autonomic blockade. Hiwatari M, et al. **Hypertension** 1985 Jul-Aug;7(4):547-53

Lack of influence of aluminum hydroxide on the bioavailability and beta-adrenoceptor blocking activity of propranolol. Hong CY, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 May;23(5):244-6

Impairment of isoniazid clearance by propranolol. Santoso B. **Int J Clin Pharmacol Ther Toxicol** 1985 Mar;23(3):134-6

Comparative pharmacokinetics of intravenous propranolol in black and white volunteers [letter] Venter CP, et al. **J Cardiovasc Pharmacol** 1985 Mar-Apr;7(2):409-10

Augmentation by propranolol of growth hormone-releasing hormone-(1-44)-NH2-induced growth hormone release in normal short and normal children. Chihara K, et al. **J Clin Endocrinol Metab** 1985 Aug;61(2):229-33

Plasma concentration-response relationships of two formulations of propranolol. DeLeve LD, et al. **J Clin Pharmacol** 1985 Apr; 25(3):182-6

Synthesis of 4'-hydroxypropranolol sulfate, a major non-beta-blocking propranolol metabolite in man. Oatis JE Jr, et al. **J Med Chem** 1985 Jun;28(6):822-4

Effect of the sialylation state of alpha 1-acid glycoprotein on propranolol binding. Primozic S, et al. **J Pharm Sci** 1985 Apr;74(4):473-5

Reduced extraction of l-propranolol by perfused rat liver in the presence of uremic blood. Terao N, et al. **J Pharmacol Exp Ther** 1985 May; 233(2):277-84

Effect of chronic treatment of propranolol on lipid metabolism in spontaneously hypertensive rats (SHR). Tonooka M, et al. **Jpn J Pharmacol** 1985 Apr;37(4):335-44

Competitive binding of quinidine, propranolol, and 4-OH-propranolol to human plasma very low-density (VLDL) and low-density (LDL) lipoproteins. Ho Ngoc-Ta Trung A, et al. **Pharm Acta Helv** 1985; 60(4):106-9

The effects of d-propranolol and captopril on post-ischaemic acute renal failure in rats. Ishigami M, et al. **Proc Eur Dial Transplant Assoc Eur Ren Assoc** 1985;21:843-8

[Effect of the central action of propranolol on coronary circulation in dogs] Xie BZ, et al. **Chung Kuo Yao Li Hsueh Pao** 1985 Mar; 6(1):33-6 (Eng. Abstr.) **(Chi)**

[Electrocardiographic studies of the modification of cardiac activity in cattle by adrenaline and noradrenaline with and without vagolysis (atropine) and beta-receptor blockade (propranolol)] Mielke H, et al. **Arch Exp Veterinarmed** 1985 Mar;39(2):193-206 (Eng. Abstr.) **(Ger)**

[The anticonvulsant action of propranolol in pentylenetetrazole-induced convulsions] Lasek R, et al. **Pharmazie** 1985 Apr;40(4):271-2 **(Ger)**

PROSTAGLANDINS

Catecholamines and contractility of the human myometrium at term: a possible role for prostaglandins. Wikland M, et al. **Acta Physiol Hung** 1985;65(3):331-4

Effects of prostaglandins on vasoconstrictor action in isolated renal arterioles. Edwards RM. **Am J Physiol** 1985 Jun; 248(6 Pt 2):F779-84

Carbon tetrachloride-induced eicosanoid synthesis and enzyme release from rat peritoneal leucocytes. Lynch TJ, et al. **Biochem Pharmacol** 1985 May 1;34(9):1515-22

Modulatory effects of prostaglandin D2, E2 and F2 alpha on the postsynaptic actions of inhibitory and excitatory amino acids in cerebellar Purkinje cell dendrites in vitro. Kimura H, et al. **Brain Res** 1985 Mar 25;330(2):235-44

Mechanisms of gonadotropin-releasing hormone and prostaglandin action on luteal cells. Leung PC. **Can J Physiol Pharmacol** 1985 Mar; 63(3):249-56 (79 ref.)

Phorbol ester regulation of rat granulosa cell prostaglandin and progesterone accumulation. Kawai Y, et al. **Endocrinology** 1985 Jun; 116(6):2320-6

Effect of verapamil & lignocaine on prostaglandin induced contractions in isolated rat uterus. Kothekar V, et al. **Indian J Med Res** 1985 Jan; 81:79-82

Role of calcium in prostaglandin induced contractile activity in rat uterus. Reddy G, et al. **Indian J Med Res** 1984 Oct;80:491-3

Beclobrinic acid--a new hypolipidemic agent--inhibits in vitro human platelet activation by blocking prostaglandin synthesis. Anwer K, et al. **Life Sci** 1985 Jul 8;37(1):63-70

Prostaglandins, catecholamines, and differentiation of the secondary palate. Greene RM, et al. **Prog Clin Biol Res** 1985;163C:277-81

Evidence against prostaglandin-mediation of somatostatin-inhibition of gastric secretions. Albinus M, et al. **Regul Pept** 1985 Mar; 10(2-3):259-66

[Physiological and pharmacological actions of prostaglandins and related substances on the endocrine system] Kasai Y, et al. **Nippon Rinsho** 1985 Mar;43(3):507-13 (38 ref.) **(Jpn)**

PSYCHIATRIC STATUS RATING SCALES

Mania. Diagnosis, state measurement and prediction of treatment response. Secunda SK, et al. **J Affective Disord** 1985 Mar-Apr;8(2):113-21

KUSTA (Kurz-Skala Stimmung/Aktivierung): a daily self-rating scale for depressive patients. Wendt G, et al. **Pharmacopsychiatry** 1985 Jan; 18(1):118-22

[Comparison of various tools for evaluating depression apropos of a study on Athymil 30 mg] Lempérière T, et al. **Ann Med Psychol (Paris)** 1984 Nov;142(9):1206-14 **(Fre)**

PSYCHIATRY

Data-based psychiatric consultation: applying mainframe computer capability to consultation. Popkin MK, et al. **Gen Hosp Psychiatry** 1985 Apr;7(2):109-12

PSYCHOLOGICAL TESTS

Behavioural and endocrine reactions in boys scoring high on Sennton neurotic scale viewing an exciting and partly violent movie and the importance of social support. Arnetz BB, et al. **Soc Sci Med** 1985; 20(7):731-6

PSYCHOMOTOR AGITATION

Emergency treatment of acute psychosis, agitation, and anxiety. Ellison JM. **Hosp Community Psychiatry** 1985 Apr;36(4):351-2

PSYCHOMOTOR PERFORMANCE

Effects of some motion sickness suppressants on static and dynamic tracking performance. Schroeder DJ, et al. **Aviat Space Environ Med** 1985 Apr;56(4):344-50

Evaluation of antimotion sickness drug side effects on performance. Wood CD, et al. **Aviat Space Environ Med** 1985 Apr;56(4):310-6

A comparison of the effects of lorazepam with those of propranolol on experimentally-induced anxiety and performance. File SE, et al. **Br J Clin Pharmacol** 1985 Apr;19(4):445-51

Increased sensitivity of the elderly to the central depressant effects of diazepam. Pomara N, et al. **J Clin Psychiatry** 1985 May;46(5):185-7

Comparison of triazolam and pentobarbital: performance impairment, subjective effects and abuse liability. Roache JD, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):120-33

Ibotenic acid lesions of the lateral hypothalamus: comparison with 6-hydroxydopamine-induced sensorimotor deficits. Dunnett SB, et al. **Neuroscience** 1985 Feb;14(2):509-18

PSYCHOPHARMACOLOGY

Fifth Italo-Soviet symposium on neuropsychopharmacology. Proceedings, Florence, November 25-26, 1983. **Ann Ist Super Sanita** 1984;20(1):1-122

Automating the measurement of locomotor activity. Beninger RJ, et al. **Neurobehav Toxicol Teratol** 1985 Jan-Feb;7(1):79-85

Automated measurement of multivariate locomotor behavior in rodents. Sanberg PR, et al. **Neurobehav Toxicol Teratol** 1985 Jan-Feb; 7(1):87-94

Proceedings of the congress of the AGNP. Nuremberg, 1983. Abstracts. **Pharmacopsychiatry** 1985 Jan;18(1):1-177

A computer-supported method for analyzing behavioral observations: studies with stereotypy. Lewis MH, et al. **Psychopharmacology (Berlin)** 1985;85(2):204-9

PSYCHOPHYSIOLOGIC DISORDERS

Psychoendocrinology and the menstrual cycle. Youngs DD, et al. **Adv Psychosom Med** 1985;12:25-34

[Auto-erythrocyte sensitization] Inbal A, et al. **Harefuah** 1984 Dec 16; 107(12):385-7 (Eng. Abstr.) **(Heb)**

[Urinary excretion of catecholamines in children with functional disorders of the digestive system] Szewczyk L, et al. **Pediatr Pol** 1984 Oct; 59(10):835-9 (Eng. Abstr.) **(Pol)**

PSYCHOSES, SUBSTANCE-INDUCED

Comparison of chlorpromazine, haloperidol and pimozide in the treatment of phencyclidine psychosis: DA-2 receptor specificity. Giannini AJ, et al. **J Toxicol Clin Toxicol** 1984-85;22(6):573-9

[Is the combination of amphetamine and chloroquine the cause of unexpected psychological symptoms?] **Lakartidningen** 1985 May 22; 82(21):1962 **(Swe)**

PSYCHOTHERAPY

Psychological treatment for benzodiazepine dependence [letter] Tyrer P, et al. **Lancet** 1985 May 4;1(8436):1042-3

PSYCHOTIC DISORDERS

Clinical characteristics of hospitalized psychotic patients who refuse antipsychotic drug therapy. Zito JM, et al. **Am J Psychiatry** 1985 Jul; 142(7):822-6

Antipsychotic and prophylactic effects of acetazolamide (Diamox) on atypical psychosis. Inoue H, et al. **Folia Psychiatr Neurol Jpn** 1984; 38(4):425-36

Emergency treatment of acute psychosis, agitation, and anxiety. Ellison JM. **Hosp Community Psychiatry** 1985 Apr;36(4):351-2

Familial differences in lithium responsive versus lithium nonresponsive psychoses. Sautter F, et al. **J Psychiatr Res** 1985;19(1):1-8

Acutely psychotic patients: a treatment approach. Wagemaker H, et al. **South Med J** 1985 Jul;78(7):833-7

[Classification of chronic psychoses types I and II and platelet serotonin levels. Apropos of 38 cases] Boudjema F, et al. **Encephale** 1985 Jan-Feb; 11(1):39-42 (Eng. Abstr.) **(Fre)**

[Lithium salts in the treatment of schizoaffective psychosis] Kopel A. **Psychiatr Pol** 1984 May-Jun;18(3):279-83 **(Pol)**

[Influence of nutritional status on intravenous pharmacokinetics of haloperidol in psychotic patients] Donoso A, et al. **Rev Med Chil** 1984 Aug;112(8):777-83 (Eng. Abstr.) **(Spa)**

QUINIDINE

Action potential prolongation and induction of abnormal automaticity by low quinidine concentrations in canine Purkinje fibers. Relationship to potassium and cycle length. Roden DM, et al. **Circ Res** 1985 Jun; 56(6):857-67

Kinetics and electrocardiographic changes after oral 3-OH-quinidine in healthy subjects. Vožeh S, et al. **Clin Pharmacol Ther** 1985 May; 37(5):575-81

Pharmacokinetics and pharmacodynamics of quinidine and its metabolite, quinidine-N-oxide, in beagle dogs. Rakhit A, et al. **Eur J Drug Metab Pharmacokinet** 1984 Oct-Dec;9(4):315-24

Elimination kinetic of high polar metabolites pool of quinidine from human serum. Camsonne R, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Feb;23(2):74-5

Quinidine-digoxin interaction: are the pharmacokinetics of both drugs altered? Rameis H. **Int J Clin Pharmacol Ther Toxicol** 1985 Mar; 23(3):145-53

Competitive binding of quinidine, propranolol, and 4-OH-propranolol to human plasma very low-density (VLDL) and low-density (LDL) lipoproteins. Ho Ngoc-Ta Trung A, et al. **Pharm Acta Helv** 1985; 60(4):106-9

REACTION TIME

Reactive capacity: a sensitive behavioral marker of movement initiation and nigrostriatal dopamine function. Spirduso WW, et al. **Brain Res** 1985 May 27;335(1):45-54

RECEPTORS, ADRENERGIC

Peripheral and central adrenergic influences on brain systems involved in the modulation of memory storage. McGaugh JL. **Ann NY Acad Sci** 1985;444:150-61

Noradrenergic modulation of selective attention: its role in memory retrieval. Sara SJ. **Ann NY Acad Sci** 1985;444:178-93

Effect of chronic desipramine treatment on adrenoceptor modulation of [3H]dopamine release from rat nucleus accumbens slices. Nurse B, et al. **Brain Res** 1985 May 20;334(2):235-42

Beta 1 and beta 2 adrenergic receptors: their role in the regulation of paradoxical sleep in the rat. Lanfumey L, et al. **Electroencephalogr Clin Neurophysiol** 1985 Jun;60(6):558-67

Parallel changes in the sensitivity of gamma-aminobutyric acid and noradrenergic receptors following chronic administration of antidepressant and GABAergic drugs. A possible role in affective disorders. Suzdak PD, et al. **Neuropharmacology** 1985 Mar; 24(3):217-22

[Effect of phenazepam on the peripheral catecholaminergic systems in immobilization stress] Malikova LA, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):23-7 (Eng. Abstr.) **(Rus)**

[Role of hypothalamic adrenoreactive structures in regulating the protective reaction to plasmin] Kalishevskaia TM, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):418-21 (Eng. Abstr.) **(Rus)**

RECEPTORS, ADRENERGIC, ALPHA

Human platelet alpha 2-adrenergic receptors: effect of Na + on interaction with the adenylate cyclase system and on epinephrine-stimulated platelet secretion. Limbird LE, et al. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:235-42

Catecholamine and opioid receptors, presynaptic inhibition of CNS neurotransmitter release, and adenylate cyclase. Mulder AH, et al. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:273-86

Alpha 2-adrenoceptor antagonism of vasopressin-induced changes in sodium excretion. Smyth DD, et al. **Am J Physiol** 1985 Jun; 248(6 Pt 2):F767-72

Thermodynamics of agonist and antagonist binding to the alpha 1-adrenoceptor studied using [125I]BE 2254. Adams A, et al. **Biochem Biophys Res Commun** 1985 Apr 30;128(2):816-23

Comparison of postnatal changes in alpha 1-adrenoceptor binding and adrenergic stimulation of phosphoinositide hydrolysis in rat cerebral cortex. Schoepp DD, et al. **Biochem Pharmacol** 1985 Aug 1; 34(15):2705-11

Platelet alpha-2-adrenergic dysfunction in negative symptom schizophrenia: a preliminary study. Rosen J, et al. **Biol Psychiatry** 1985 May;20(5):539-45

Acetylcholine release from rat atria can be regulated through an alpha 1-adrenergic receptor. Wetzel GT, et al. **Circ Res** 1985 May; 56(5):763-6

Alpha 1-adrenergic responsiveness of young adult and aged rat submandibular cells in vitro. Baum BJ, et al. **Comp Biochem Physiol** [C] 1985;81(1):121-4

Trials of serotonin, substance P and alpha 2-adrenergic receptor effects on the equine large colon. Sellers AF, et al. **Cornell Vet** 1985 Apr; 75(2):319-23

Evidence for alpha 1-adrenergic stimulatory control of in vitro release of immunoreactive thyrotropin-releasing hormone from rat median eminence: in vivo corroboration. Tapia-Arancibia L, et al. **Endocrinology** 1985 Jun;116(6):2314-9

Dopamine preferentially stimulates postsynaptic alpha 2-adrenoceptors in the femoral vascular bed, but alpha 1-adrenoceptors in the renal vascular bed of the anaesthetised dog. Duval N, et al. **Eur J Pharmacol** 1985 Feb 5;108(3):265-72

Inhibition by 5,6-dihydroxy-2-dimethylaminotetralin (M7) of noradrenergic neurotransmission in the rabbit hypothalamus: role of alpha-2 adrenoceptors and of dopamine receptors. Galzin AM, et al. **J Pharmacol Exp Ther** 1985 May;233(2):459-65

Demonstration of an alpha adrenoceptor-mediated inotropic effect of norepinephrine in human atria. Skomedal T, et al. **J Pharmacol Exp Ther** 1985 May;233(2):441-6

Modulation of a transient outward current in serotonergic neurones by alpha 1-adrenoceptors. Aghajanian GK. **Nature** 1985 Jun 6-12; 315(6019):501-3

6-Hydroxydopamine pretreatment effects on alpha- and beta-adrenergic receptor adaptation to clorgyline. Cohen RM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):158-61

alpha 1- and beta-adrenergic receptors are co-regulated during both noradrenergic denervation and hyperinnervation. Sutin J, et al. **Neuroscience** 1985 Apr;14(4):973-80

[Dopamine-induced up-regulation of alpha 2-adrenoceptors in crude synaptic membranes of rat brain] Kohno Y, et al. **Nippon Yakurigaku Zasshi** 1985 Mar;85(3):173-83 (Eng. Abstr.) **(Jpn)**

RECEPTORS, ADRENERGIC, BETA

Increase in serotonin2 receptor density in rat cerebral cortex slices by stimulation of beta-adrenergic receptors. Scott JA, et al. **Biochem Pharmacol** 1985 May 1;34(9):1585-8

Mechanisms of supersensitivity to sympathomimetic amines in the chronically denervated heart of the conscious dog. Vatner DE, et al. **Circ Res** 1985 Jul;57(1):55-64

Receptor mechanisms in fish chromatophores--VIII. Mediated by beta adrenoceptors, catecholamines always act to disperse pigment in siluroid melanophores. Fujii R, et al. **Comp Biochem Physiol** [C] 1985; 81(1):1-6

Why is amitriptyline much weaker than desipramine at decreasing beta-adrenoceptor numbers? Wise H, et al. **Eur J Pharmacol** 1985 Mar 26;110(1):137-41

The effect of age on beta-adrenergic function in man: a review. Ebstein RP, et al. **Isr J Med Sci** 1985 Mar;21(3):302-11

Evidence for a beta-adrenoceptor-mediated regulation of human natural killer cells. Hellstrand K, et al. **J Immunol** 1985 Jun;134(6):4095-9

Radioreceptor assay for beta-adrenergic receptor-reactive catecholamines in serum samples. Iwo K, et al. **J Lab Clin Med** 1985 Jun; 105(6):711-7

Effects of clenbuterol and antidepressant drugs on beta adrenergic receptor/N-protein coupling in the cerebral cortex of the rat. O'Donnell JM, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):30-6

Chronic thyroxine treatment of rats down-regulates the noradrenergic cyclic AMP generating system in cerebral cortex. Schmidt BH, et al. **J Pharmacol Exp Ther** 1985 May;233(2):466-72

Effects of beta-adrenoceptor antagonist administration on beta 2-adrenoceptor density in human lymphocytes. The role of the 'intrinsic sympathomimetic activity'. Brodde OE, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):417-22

6-Hydroxydopamine pretreatment effects on alpha- and beta-adrenergic receptor adaptation to clorgyline. Cohen RM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):158-61

Down-regulation of beta-adrenoceptors in rat cortex by repeated administration of desipramine, electroconvulsive shock and clenbuterol requires 5-HT neurones but not 5-HT. Nimgaonkar VL, et al. **Neuropharmacology** 1985 Apr;24(4):279-83

alpha 1- and beta-adrenergic receptors are co-regulated during both noradrenergic denervation and hyperinnervation. Sutin J, et al. **Neuroscience** 1985 Apr;14(4):973-80

The activation of mice's behavior and reduction of brain beta-adrenergic receptor binding following repeated administration of antidepressant drugs. Nomura S, et al. **Yakubutsu Seishin Kodo** 1984 Nov; 4(3):237-41

RECEPTORS, CHOLINERGIC

Comparative effects of aprophen, atropine and benactyzine on central and peripheral cholinoceptors and on acetylcholinesterase. Dawson RM, et al. **Biochem Pharmacol** 1985 May 1;34(9):1577-9

Affinity-dependent cross-linking to neurotoxin sites of the acetylcholine receptor mediated by catechol oxidation. Nickoloff BJ, et al. **Biochemistry** 1985 Feb 12;24(4):999-1007

Blockade of cholinergic receptors in the C1 area abolishes hypertensive response to opiates in the A1 area of the ventrolateral medulla. Punnen S, et al. **Brain Res** 1985 Jun 10;336(1):180-6

Cholinergic-muscarinic receptors do not mediate growth hormone release in response to baclofen, a gamma-aminobutyric acid agonist, in humans. Coiro V, et al. **Horm Metab Res** 1985 May;17(5):260-1

High-affinity binding of [3H]acetylcholine to muscarinic cholinergic receptors. Kellar KJ, et al. **J Neurosci** 1985 Jun;5(6):1577-82

[Effect of RNAse inhibitors and activators on acetylcholine interaction with the cholinoreceptor in a tissue extract] Turpaev TM, et al. **Dokl Akad Nauk SSSR** 1985;281(2):500-2 **(Rus)**

[Possible participation of slow Na+--Ca++ channels in realizing cholinergic effects on the cardiac pacemaker] Sukhova GS, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):506-9 (Eng. Abstr.) **(Rus)**

RECEPTORS, DOPAMINE

Effect of metoclopramide, domperidone and apomorphine on GH secretion in children and adolescents. Massara F, et al. **Acta Endocrinol (Copenh)** 1985 Apr;108(4):451-5

Effect of dopamine receptor stimulation on the inhibition of LH pulsatility by a met-enkephaline (FK 33-824). del Pozo E, et al. **Acta Neurochir (Wien)** 1985;75(1-4):88-90

Age-related changes in rat brain dopaminergic receptors. Petkov VV, et al. **Acta Physiol Pharmacol Bulg** 1984;10(4):16-27

On the role of dopamine receptors in aldosterone secretion. Frisina N, et al. **Ann Endocrinol (Paris)** 1984;45(6):387-91

Dopamine D2 receptors modulate neurotransmitter-regulated calcium ion gates. Memo M, et al. **Ann Ist Super Sanita** 1984;20(1):5-10

SCH 23390 may alter dopamine-mediated motor behaviour via striatal D-1 receptors. Boyce S, et al. **Biochem Pharmacol** 1985 May 15; 34(10):1665-9

Dopamine autoreceptors and the effects of drugs on locomotion and dopamine synthesis. Brown F, et al. **Br J Pharmacol** 1985 Apr; 84(4):853-60

Rapid desensitization of presynaptic dopamine autoreceptors during exposure to exogenous dopamine. Arbilla S, et al. **Brain Res** 1985 Jun 24;337(1):11-7

The possible role of 2-hydroxyestradiol in the development of estrogen-induced striatal dopamine receptor hypersensitivity. Clopton JK, et al. **Brain Res** 1985 Apr 29;333(1):1-10

Effects of pertussis toxin on D2-dopamine receptor in rat striatum: evidence for coupling of Ni regulatory protein with D2-receptor. Fujita N, et al. **Brain Res** 1985 May 6;333(2):231-6

Dopamine receptors regulate Met-enkephalin content in pituitary. George SR, et al. **Brain Res** 1985 May 13;334(1):187-9

Low doses of apomorphine elicit two opposing influences on dopamine cell electrophysiology. Grace AA, et al. **Brain Res** 1985 May 6; 333(2):285-98

Effect of duration of haloperidol treatment on DA receptor supersensitization in aging C57BL/6J mice. Randall PK, et al. **Brain Res** 1985 Apr 29;333(1):85-95

Regional sensitivity of neuroleptic receptors to sub-acute soman intoxication. Valdes JJ, et al. **Brain Res Bull** 1985 Feb;14(2):117-21

Dopamine: receptors and clinical applications. Goldberg LI. **Clin Physiol Biochem** 1985;3(2-3):120-6 (33 ref.)

An investigation of amphetamine-induced release of 5-HT from rat hippocampal slices. Balfour DJ, et al. **Eur J Pharmacol** 1985 Mar 12; 109(3):395-9

Evidence of dopamine involvement in the effect of repeated treatment with various antidepressants in the behavioural 'despair' test in rats. Borsini F, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):253-6

Striatal synaptosomal dopamine synthesis: evidence against direct regulation by an autoreceptor mechanism. Compton DR, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):157-62

Selective D-1 dopamine receptor increase following chronic treatment with SCH 23390. Creese I, et al. **Eur J Pharmacol** 1985 Feb 12; 109(1):127-8

Magnesium ions reveal nanomolar potency of dopamine at [3H]spiperone labelled D-2 receptors in rat corpus striatum. De Vries DJ, et al.

Eur J Pharmacol 1985 Mar 12;109(3):417-9

Sedation and sleep induced by high doses of apomorphine after blockade of D-1 receptors by SCH 23390. Gessa GL, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):269-74

N-methyl,N-propargyl-2-aminotetralins:novel dopamine agonists with monoamine oxidase inhibiting properties. Hazelhoff B, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):229-40

Effect of the dopamine D-1 antagonist SCH 23390 on rotational behaviour induced by apomorphine and pergolide in 6-hydroxy-dopamine denervated rats. Herrera-Marschitz M, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):349-54

Chronic haloperidol does not alter agonist affinity for dopamine receptors in vitro. Meller E, et al. **Eur J Pharmacol** 1985 Mar 12; 109(3):389-94

Sniffing, rearing and locomotor responses to the D-1 dopamine agonist R-SK&F 38393 and to apomorphine: differential interactions with the selective D-1 and D-2 antagonists SCH 23390 and metoclopramide. Molloy AG, et al. **Eur J Pharmacol** 1985 Feb 5;108(3):305-8

Dopamine receptor subtypes: in vivo biochemical evidence for functional interaction. Saller CF, et al. **Eur J Pharmacol** 1985 Feb 26; 109(2):297-300

Reduced sensitivity of synaptosomal dopamine autoreceptors following increase in synaptosomal dopamine synthesis. Tissari AH. **Eur J Pharmacol** 1985 Mar 12;109(3):433-4

The supersensitivity of dopaminergic neurons to apomorphine in rats following chronic haloperidol. Vogelsang GD, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):267-9

The dopamine autoreceptor agonist B-HT 920 markedly stimulates sexual behavior in male rats. Ferrari F, et al. **Experientia** 1985 May 15; 41(5):636-8

Resolution of 5,6-dihydroxy-2-(N,N-di-n-propylamino)tetralin in relation to the structural and stereochemical requirements for centrally acting dopamine agonists. Grol CJ, et al. **J Med Chem** 1985 May; 28(5):679-83

Sulpiride blocks postsynaptic dopamine receptors in the nucleus accumbens. Morgenstern R, et al. **J Neural Transm** 1985; 61(3-4):151-60

Effects of SK&F 82526 and SK&F 83742 on the renal vascular dopamine receptor. Schmidt M, et al. **J Pharmacol** 1985 Jan-Mar;16(1):15-22

Computer imaging and analysis of dopamine (D2) and serotonin (S2) binding sites in rat basal ganglia or neocortex labeled by [3H]spiroperidol. Altar CA, et al. **J Pharmacol Exp Ther** 1985 May; 233(2):527-38

Inhibition by 5,6-dihydroxy-2-dimethylaminotetralin (M7) of noradrenergic neurotransmission in the rabbit hypothalamus: role of alpha-2 adrenoceptors and of dopamine receptors. Galzin AM, et al. **J Pharmacol Exp Ther** 1985 May;233(2):459-65

Acute and subchronic effects of MJ-13859, a potential antipsychotic drug, on rat brain dopaminergic function. McMillen BA. **J Pharmacol Exp Ther** 1985 May;233(2):369-75

Inactivation of D1 and D2 dopamine receptors by N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline in vivo: selective protection by neuroleptics. Meller E, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):656-62

D-2 dopamine receptors in aging mouse striatum: determination of high- and low-affinity agonist binding sites. Severson JA, et al. **J Pharmacol Exp Ther** 1985 May;233(2):361-8

Comparison of chlorpromazine, haloperidol and pimozide in the treatment of phencyclidine psychosis: DA-2 receptor specificity. Giannini AJ, et al. **J Toxicol Clin Toxicol** 1984-85;22(6):573-9

Dopamine inhibition of anterior pituitary adenylate cyclase is mediated through the high-affinity state of the D2 receptor. Borgundvaag B, et al. **Life Sci** 1985 Jul 29;37(4):379-86

Reserpine-induced hypothermia and its reversal by dopamine agonists. Danielson TJ, et al. **Life Sci** 1985 Jul 8;37(1):31-8

The putative dopamine autoreceptor agonist B-HT 920 decreases nigral dopamine cell firing rate and prolactin release in rat. Eriksson E, et al. **Life Sci** 1985 May 13;36(19):1819-27

Dopamine receptor antagonists inhibit the natriuretic response to atrial natriuretic factor (ANF). Marin-Grez M, et al. **Life Sci** 1985 Jun 3; 36(22):2171-6

SCH23390 causes persistent antidopaminergic effects in vivo: evidence for longterm occupation of receptors. Schulz DW, et al. **Life Sci** 1985 May 20;36(20):1941-8

D2-dopamine receptor-mediated inhibition of cyclic AMP formation in striatal neurons in primary culture. Weiss S, et al. **Mol Pharmacol** 1985 Jun;27(6):595-9

Unexpected potentiation by discriminant benzamide derivatives of stereotyped behaviours elicited by dopamine agonists in mice. Vasse M, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):108-16

Effect of gestational and neonatal styrene exposure on dopamine receptors. Zaidi NF, et al. **Neurobehav Toxicol Teratol** 1985 Jan-Feb;7(1):23-8

The effects of neurotensin and [D-Tyr11]-NT on the hyperactivity induced by intra-accumbens administration of a potent dopamine receptor agonist. Jolicoeur FB, et al. **Neuropeptides** 1985 Apr; 6(2):143-56

The continuity of dopamine receptor antagonism can dictate the long-term behavioural consequences of a mesolimbic infusion of dopamine. Costall B, et al. **Neuropharmacology** 1985 Mar;24(3):193-7

Striatal topography of D-2 receptors correlates with indexes of cholinergic neuron localization. Joyce JN, et al. **Neurosci Lett** 1985 Jan 7;53(1):127-31

Lack of effect of intranigral administration of a dopamine analogue, (+/-)-3-(3-hydroxyphenyl)-N,n-propylpiperidine [(+/-)-3-PPP], on nigrostriatal dopamine neurones. Kelly E, et al. **Neurosci Lett** 1985 May 1;56(1):57-62

Regulation of dopamine release by impulse flow and by autoreceptors as studied by in vivo voltammetry in the rat striatum. Gonon FG, et al. **Neuroscience** 1985 Mar;14(3):765-74

Increased investigative activity after presynaptic dopaminergic stimulation measured by a fixed-interval recording procedure. Höglund AU, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):403-6

Effect of chronic apomorphine on the development of denervation supersensitivity. Robin M, et al. **Pharmacol Biochem Behav** 1985 Apr; 22(4):547-51

Effects of selective dopamine receptor agonists in rats trained to discriminate apomorphine from saline. Woolverton WL, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):577-81

Substituted benzamides as ligands for visualization of dopamine receptor binding in the human brain by positron emission tomography. Farde L, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(11):3863-7

Differential involvement of dopamine D-1 and D-2 receptors in the circling behaviour induced by apomorphine, SK & F 38393, pergolide and LY 171555 in 6-hydroxydopamine-lesioned rats. Arnt J, et al. **Psychopharmacology (Berlin)** 1985;85(3):346-52

Characterization of the bupropion cue in the rat: lack of evidence for a dopaminergic mechanism. Blitzer RD, et al. **Psychopharmacology (Berlin)** 1985;85(2):173-7

Chronic haloperidol during development attenuates dopamine autoreceptor function in striatal and mesolimbic brain regions of young and older adult rats. Scalzo FM, et al. **Psychopharmacology (Berlin)** 1985;85(3):271-6

Differential effects of dopamine D-1 and D-2 agonists and antagonists in 6-hydroxydopamine-lesioned rats. Arnt J. **Psychopharmacology [Suppl]** 1985;2:60-1

Intermittent treatment with droperidol, a short-acting neuroleptic, increases behavioral dopamine receptor sensitivity. Belmaker RH, et al. **Psychopharmacology [Suppl]** 1985;2:194-9

Pharmacological differentiation of dopamine D-1 and D-2 antagonists after single and repeated administration. Christensen AV, et al. **Psychopharmacology [Suppl]** 1985;2:182-90

Receptor-binding profiles of neuroleptics. Hyttel J, et al. **Psychopharmacology [Suppl]** 1985;2:9-18

Differential alteration of striatal D-1 and D-2 receptors induced by the long-term administration of haloperidol, sulpiride or clozapine to rats. Jenner P, et al. **Psychopharmacology [Suppl]** 1985;2:174-81

Induction and reversal of dopamine dyskinesia in rat, cat, and monkey. Lloyd KG, et al. **Psychopharmacology [Suppl]** 1985;2:200-10

Influence of GABA mimetics and lithium on biochemical manifestations of striatal dopamine target cell hypersensitivity. Scatton B, et al. **Psychopharmacology [Suppl]** 1985;2:39-45

Functional classification of different dopamine receptors. Ungerstedt U, et al. **Psychopharmacology [Suppl]** 1985;2:19-30

Effect of dopamine and dopamine-receptor blockade on in vitro renin release, tissue renin content and tissue cyclic AMP content in the rat. López GA, et al. **Rev Esp Fisiol** 1985 Mar;41(1):95-100

[Continuous suppression of methamphetamine-induced supersensitivity by chronic haloperidol administration] Kashihara K, et al. **Seishin Shinkeigaku Zasshi** 1984;86(11):928-32 **(Jpn)**

[Role of serotonin and dopamine receptors in the mechanism of action of haloperidol and pirenperone] Maimets MO, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):15-8 (Eng. Abstr.) **(Rus)**

RECEPTORS, DRUG

Synthesis and structure-activity studies on excitatory amino acids structurally related to ibotenic acid. Krogsgaard-Larsen P, et al. **J Med Chem** 1985 May;28(5):673-9

RECEPTORS, ENDOGENOUS SUBSTANCES

Adenosine, adenylate cyclase, and transmitter release. Phillis JW, et al. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:243-57 (81 ref.)

Endocrine-mediated parallel changes in hepatic glucocorticoid and prolactin receptors. Dave JR, et al. **Biochim Biophys Acta** 1985 May 30;845(2):276-82

Regulation of infant and developing rat testicular gonadotropin and prolactin receptors and steroidogenesis by treatments with human chorionic gonadotropin, gonadotropin-releasing hormone analogs, bromocriptine, prolactin, and estrogen. Huhtaniemi IT, et al. **Biol Reprod** 1985 May;32(4):721-32

Somatostatin-14 and somatostatin-28 pretreatment down-regulate somatostatin-14 receptors and have biphasic effects on forskolin-stimulated cyclic adenosine, 3',5'-monophosphate synthesis and adrenocorticotropin secretion in mouse anterior pituitary tumor cells. Heisler S, et al. **Endocrinology** 1985 Jul;117(1):217-25

The frequency of gonadotropin-releasing hormone stimulation determines the number of pituitary gonadotropin-releasing hormone receptors. Katt JA, et al. **Endocrinology** 1985 May;116(5):2113-5

Tunicamycin and neuraminidase effects on luteinizing hormone (LH)-releasing hormone binding and LH release from rat pituitary cells in culture. Schvartz I, et al. **Endocrinology** 1985 Jun;116(6):2341-6

Interaction of growth hormone-releasing factor (GRF) and 14 GRF analogs with vasoactive intestinal peptide (VIP) receptors of rat pancreas. Discovery of (N-Ac-Tyr1,D-Phe2)-GRF(1-29)-NH2 as a VIP antagonist. Waelbroeck M, et al. **Endocrinology** 1985 Jun;116(6):2643-9

Increased hepatic and reduced prostatic prolactin (PRL) binding in iron deficiency and during neuroleptic treatment: correlation with changes in serum PRL and testosterone. Barkey RJ, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):193-200

3,5,3'-Triiodothyronine receptors and thyroxine 5'-monodeiodinating activity in thyroid hormone-insensitive amphibia. Galton VA. **Gen Comp Endocrinol** 1985 Mar;57(3):465-71

A unique control mechanism in the regulation of insulin secretion. Secretagogue-induced somatostatin receptor recruitment. Draznin B, et al. **J Clin Invest** 1985 May;75(5):1510-6

Neuropeptides and their receptors: a psychosomatic network. Pert CB, et al. **J Immunol** 1985 Aug;135(2 Suppl):820s-826s

Evolutionary origins of neuropeptides, hormones, and receptors: possible applications to immunology. Roth J, et al. **J Immunol** 1985 Aug;135(2 Suppl):816s-819s

Localization of somatostatin receptors in secretion vesicles in anterior pituitary cells and pancreatic islets. Draznin B, et al. **J Recept Res** 1985;5(1):83-103

Photoaffinity labelling of MSH receptors on Anolis melanophores: effects of catecholamines, calcium and forskolin. Eberle AN, et al. **J Recept Res** 1985;5(1):59-81

Changes in pituitary and ovarian LHRH receptors after active immunization of female rats against LH or LHRH. Popkin RM, et al. **J Reprod Fertil** 1985 Mar;73(2):491-6

Newborn and immature rat testes contain gonadotropin-releasing hormone (GnRH) receptors, and their testosterone production is stimulated by a GnRH agonist in vitro. Huhtaniemi IT, et al. **Mol Cell Endocrinol** 1985 Apr;40(1):41-4

Receptor-mediated degradation of human growth hormone in rat adipocytes and cultured human lymphocytes (IM-9). Weyer B, et al. **Mol Cell Endocrinol** 1985 Jun;41(1):85-92

Increased gonadotrophin releasing hormone receptors on pituitary gonadotrophs: effect on subsequent LH secretion. Young LS, et al. **Mol Cell Endocrinol** 1985 Jun;41(1):69-78

Treatment of rats with the TRH analog MK-771. Down-regulation of TRH receptors and behavioral tolerance. Simasko SM, et al. **Neuropharmacology** 1985 Feb;24(2):157-65

Products of cholecystokinin (CCK)-octapeptide proteolysis interact with central CCK receptors. Steardo L, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):319-25

Somatostatin analogs: correlation of receptor affinity with inhibition of cyclic AMP formation in pancreatic acinar cells. Taparel D, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):109-14

Up-regulation of thyrotropin-releasing hormone (TRH) receptors in rat spinal cord after codepletion of serotonin and TRH. Ogawa N, et al. **Regul Pept** 1985 Mar;10(2-3):85-90

RECEPTORS, ENDORPHIN

Catecholamine and opioid receptors, presynaptic inhibition of CNS neurotransmitter release, and adenylate cyclase. Mulder AH, et al. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:273-86

Effects of tifluadom on passive avoidance behaviour in DBA/2 mice. Pavone F, et al. **Behav Brain Res** 1985 May;15(3):177-81

Modification of opioid ligand binding in the central and the peripheral nervous system by different buffers. Bourhim N, et al. **Biochem Biophys Res Commun** 1985 Jun 14;129(2):328-33

Central nervous system opiate and 5-hydroxytryptamine influences on baroreflex control of the coronary circulation. Moore PG, et al. **J Auton Nerv Syst** 1985 Feb-Mar;12(2-3):185-94

Mu1: a very high affinity subtype of enkephalin binding sites in rat brain. Lutz RA, et al. **Life Sci** 1985 Jun 10;36(23):2233-8

Characterization of rat brain opioid receptors by [Tyr-3,5-3H]1, D-Ala2, Leu5-enkephalin binding. Benyhe S, et al. **Neurochem Res** 1985 May;10(5):627-35

Studies in vitro with ICI 174,864, [D-Pen2, D-Pen5]-enkephalin (DPDPE) and [D-Ala2, NMePhe4, Gly-ol]-enkephalin (DAGO). Hirning LD, et al. **Neuropeptides** 1985 Feb;5(4-6):383-6

Postnatal development of opioid systems in rat brain. Loughlin SE, et al. **Neuropeptides** 1985 Feb;5(4-6):469-72

The interaction of the two isomers of the opioid benzodiazepine tifluadom with mu-, delta-, and kappa-binding sites and their analgesic and intestinal effects in rats. Petrillo P, et al. **Neuropeptides** 1985 Feb;5(4-6):403-6

Opiate receptor-mediated chemotaxis of human monocytes. Ruff MR, et al. **Neuropeptides** 1985 Feb;5(4-6):363-6

Opiate and histamine H1 receptors are present on some substance P-containing dorsal root ganglion cells. Ninkovic M, et al. **Neurosci Lett** 1985 Jan 7;53(1):133-7

Astrocyte opioid receptors: activation modifies the noradrenaline-evoked increase in 2-[14C]deoxyglucose incorporation into glycogen. Pearce B, et al. **Neurosci Lett** 1985 Apr 9;55(2):157-60

Acupuncture analgesia [letter] Han JS. **Pain** 1985 Mar;21(3):307-10

Binding characteristics of dermorphin, and [dermorphin1-7]-beta c-endorphin in rat brain membranes. Westphal M, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):149-52

[The nature of cation-binding groups in binding sites for [[3H]Tyr1, D-Ala2, D-Leu5]enkephalin] Zaitsev SV, et al. **Bioorg Khim** 1985 Feb;11(2):153-61 (Eng. Abstr.) **(Rus)**

RECEPTORS, GABA-BENZODIAZEPINE

Foot shock-induced decrease of low affinity GABA receptors in the rat brain: antagonism by diazepam. Concas A, et al. **Ann Ist Super Sanita** 1984;20(1):53-6

Central effects of nicotinamide and inosine which are not mediated through benzodiazepine receptors. Bold JM, et al. **Br J Pharmacol** 1985 Mar;84(3):689-96

Prenatal exposure to diazepam results in enduring reductions in brain receptors and deep slow wave sleep. Livezey GT, et al. **Brain Res** 1985 May 20;334(2):361-5

Specific [3H]gamma-aminobutyric acid binding to vestibular membranes of the chick inner ear. Meza G, et al. **Brain Res** 1985 Jun 24;337(1):179-83

Differential modulation of gamma-aminobutyric acid receptors by caprolactam derivatives with central nervous system depressant or convulsant activity. Skerritt JH, et al. **Brain Res** 1985 Apr 8;331(2):225-33

Heterogeneity of brain benzodiazepine receptors: effects of physiological conditions. Lippa AS, et al. **Brain Res Bull** 1985 Feb;14(2):189-95

Pharmacological evidence that the non-neuronal diazepam binding site in primary cultures of glial cells is associated with a calcium channel. Bender AS, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):287-8

Benzodiazepine receptor photoaffinity labeling: correlation of function with binding. Gibbs TT, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):171-80

Spontaneous and RO 15-1788-induced reversal of subsensitivity to GABA following chronic benzodiazepines. Gonsalves SF, et al. **Eur J Pharmacol** 1985 Apr 2;110(2):163-70

Synthesis and interaction of 5-(substituted-phenyl)-3-methyl-6,7-dihydropyrazolo[4,3-e][1,4]diazepin-8(7H)-ones with benzodiazepine receptors in rat cerebral cortex. Baraldi PG, et al. **J Med Chem** 1985 May;28(5):683-5

3-Amino-beta-carboline derivatives and the benzodiazepine receptor. Synthesis of a selective antagonist of the sedative action of diazepam. Dodd RH, et al. **J Med Chem** 1985 Jun;28(6):824-8

gamma-Aminobutyric acid: temperature dependence in benzodiazepine receptor binding. Chweh AY, et al. **J Neurochem** 1985 Jul;45(1):240-3

Triazolam, an anomalous benzodiazepine receptor ligand: in vitro characterization of alprazolam and triazolam binding. Clow A, et al. **J Neurochem** 1985 Aug;45(2):621-5

Differential degradation of different benzodiazepine binding proteins by incubation of membranes from cerebellum or hippocampus with trypsin. Eichinger A, et al. **J Neurochem** 1985 Jul;45(1):219-26

Radiation inactivation studies of the benzodiazepine/gamma-aminobutyric acid/chloride ionophore receptor complex. Schwartz RD, et al. **J Neurochem** 1985 Jul;45(1):108-15

'Peripheral-type' binding sites for benzodiazepines in brain: relationship to the convulsant actions of Ro 5-4864. Weissman BA, et al. **J Neurochem** 1985 May;44(5):1494-9

Effects of acute and chronic treatment on the pro- and anti-convulsant actions of CL 218, 872, PK 8165 and PK 9084, putative ligands for the benzodiazepine receptor. File SE, et al. **J Pharm Pharmacol** 1985 Apr;37(4):252-6

Daily rhythms of benzodiazepine receptor numbers in frontal lobe and cerebellum of the rat. Brennan MJ, et al. **Life Sci** 1985 Jun 17;36(24):2333-7

Prenatal stress impairs maternal behavior in a conflict situation and reduces hippocampal benzodiazepine receptors. Fride E, et al. **Life Sci** 1985 Jun 3;36(22):2103-9

Reduction of GABAB receptor binding induced by climbing fiber degeneration in the rat cerebellum. Kato K, et al. **Life Sci** 1985 Jul 22;37(3):279-88

The effects of benzodiazepines on spinal homosynaptic depression. Davies MF, et al. **Neuropharmacology** 1985 Apr;24(4):301-7

The influence of bicarbonate ions on the GABA-mimetic activity of ethylenediamine. Hill DR. **Neuropharmacology** 1985 Feb;24(2):147-55

Parallel changes in the sensitivity of gamma-aminobutyric acid and noradrenergic receptors following chronic administration of antidepressant and GABAergic drugs. A possible role in affective disorders. Suzdak PD, et al. **Neuropharmacology** 1985 Mar; 24(3):217-22

gamma-Aminobutyric acid modulation of benzodiazepine receptor binding in vitro does not predict the pharmacologic activity of all benzodiazepine receptor ligands. Chweh AY, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):173-7

Are the anxiogenic effects of yohimbine mediated by its action at benzodiazepine receptors? Pellow S, et al. **Neurosci Lett** 1985 Mar 22; 55(1):5-9

Autoreceptors regulate gamma-[3H]aminobutyric acid release from the guinea pig small intestine. Taniyama K, et al. **Neurosci Lett** 1985 Apr 9;55(2):245-8

On the location of gamma-aminobutyrate and benzodiazepine receptors in the cerebellum of the normal C3H and Lurcher mutant mouse. Fry JP, et al. **Neuroscience** 1985 Apr;14(4):1091-101

Pharmacology of benzodiazepine antagonists. Haefely W. **Pharmacopsychiatry** 1985 Jan;18(1):163-6

The anxiolytic activity of beta-carboline derivatives in mice, and its separation from ataxic properties. Stephens DN, et al. **Pharmacopsychiatry** 1985 Jan;18(1):167-70

The effects of compounds related to gamma-aminobutyrate and benzodiazepine receptors on behavioural responses to anxiogenic stimuli in the rat: punished barpressing. Quintero S, et al. **Psychopharmacology (Berlin)** 1985;85(2):244-51

RECEPTORS, SEROTONIN

Increase in serotonin2 receptor density in rat cerebral cortex slices by stimulation of beta-adrenergic receptors. Scott JA, et al. **Biochem Pharmacol** 1985 May 1;34(9):1585-8

Tryptamine-induced vasoconstrictor responses in rat caudal arteries are mediated predominantly via 5-hydroxytryptamine receptors. Bradley PB, et al. **Br J Pharmacol** 1985 Apr;84(4):919-25

A behavioural and biochemical study in mice and rats of putative selective agonists and antagonists for 5-HT1 and 5-HT2 receptors. Goodwin GM, et al. **Br J Pharmacol** 1985 Mar;84(3):743-53

Serotonin release in human cerebral cortex and its modulation via serotonin receptors. Schlicker E, et al. **Brain Res** 1985 Apr 8; 331(2):337-41

Progesterone stimulates sexual behaviour in female rats by increasing 5-HT activity on 5-HT2 receptors. Wilson CA, et al. **Brain Res** 1985 May 6;333(2):223-9

A molecular theory of recognition and activation at a 5-HT receptor based on a quantum chemical approach to structure activity relationships. Osman R, et al. **Clin Physiol Biochem** 1985;3(2-3):80-8

Acute and chronic phencyclidine administration changes serotonin receptors in rat brain. Nabeshima T, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):129-30

Two 5-HT receptors linked to adenylate cyclase in guinea pig hippocampus are discriminated by 5-carboxamidotryptamine and spiperone. Shenker A, et al. **Eur J Pharmacol** 1985 Mar 12; 109(3):427-9

The enteric neural receptor for 5-hydroxytryptamine. Gershon MD, et al. **Experientia** 1985 Jul 15;41(7):863-8

Evidence that phospholipid turnover is the signal transducing system coupled to serotonin-S2 receptor sites. de Chaffoy de Courcelles D, et al. **J Biol Chem** 1985 Jun 25;260(12):7603-8

5-Hydroxytryptamine stimulates inositol phosphate production in a cell-free system from blowfly salivary glands. Evidence for a role of GTP in coupling receptor activation to phosphoinositide breakdown. Litosch I, et al. **J Biol Chem** 1985 May 10;260(9):5464-71

Bioactive conformation of 1-arylpiperazines at central serotonin receptors. Huff JR, et al. **J Med Chem** 1985 Jul;28(7):945-8

Cardiovascular effects in the Sprague-Dawley rat of 8-hydroxy-2(di-N-propylamino) tetralin, a selective 5-hydroxytryptamine receptor agonist. Gradin K, et al. **J Pharm Pharmacol** 1985 Apr;37(4):263-5

Computer imaging and analysis of dopamine (D2) and serotonin (S2) binding sites in rat basal ganglia or neocortex labeled by [3H]spiroperidol. Altar CA, et al. **J Pharmacol Exp Ther** 1985 May; 233(2):527-38

5-Hydroxytryptamine receptor in isolated rabbit aorta: characterization with tryptamine analogs. Clancy BM, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):761-9

5-Hydroxytryptamine-stimulated inositol phospholipid hydrolysis in rat cerebral cortex slices: pharmacological characterization and effects of antidepressants. Kendall DA, et al. **J Pharmacol Exp Ther** 1985 May; 233(2):473-9

Do D 600 and diltiazem interact with serotonin receptors in rabbit vascular tissues? Ohashi M, et al. **J Pharmacol Exp Ther** 1985 Jun; 233(3):830-5

Receptor-binding properties in vitro and in vivo of ritanserin: A very potent and long acting serotonin-S2 antagonist. Leysen JE, et al. **Mol Pharmacol** 1985 Jun;27(6):600-11

Decreased 5-HT2 but not 5-HT1 receptor binding in cortex of rat after chronic administration of dothiepin. Application of the Woolf plot to analysis of binding parameters. Diggory GL, et al. **Neuropharmacology** 1985 Apr;24(4):275-8

Down-regulation of beta-adrenoceptors in rat cortex by repeated administration of desipramine, electroconvulsive shock and clenbuterol requires 5-HT neurones but not 5-HT. Nimgaonkar VL, et al. **Neuropharmacology** 1985 Apr;24(4):279-83

[Central serotonin receptors] Fillion G. **Pathol Biol (Paris)** 1985 Apr; 33(4):221-6 (56 ref.) **(Fre)**

[Structure of the binding center of the serotonin S2 receptor] Kats MM. **Biol Nauki** 1985;(3):19-24 (Eng. Abstr.) **(Rus)**

[pH changes in the matrix of serotonin organelles of stimulated thrombocytes] Kozlov VK, et al. **Biull Vsesoiuznogo Kardiol Nauchn Tsentra AMN SSSR** 1985; 8(1):77-82 (Eng. Abstr.) **(Rus)**

[Role of serotonin and dopamine receptors in the mechanism of action of haloperidol and pirenperone] Maimets MO, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):15-8 (Eng. Abstr.) **(Rus)**

REFLEX

Anterior hypothalamic lesions impair reflex bradycardia selectively in rats. Miyajima E, et al. **Am J Physiol** 1985 Jun;248(6 Pt 2):H937-44

The role of substance P as a neurotransmitter in the reflexes of slow time courses in the neonatal rat spinal cord. Akagi H, et al. **Br J Pharmacol** 1985 Mar;84(3):663-73

Attenuation of the reflex pressor response to muscular contraction by a substance P antagonist. Kaufman MP, et al. **Brain Res** 1985 Apr 29; 333(1):182-4

Effects of catecholamines on spinal motoneurones and spinal reflex discharges in the isolated spinal cord of the newborn rat. Kitazawa T, et al. **Brain Res** 1985 Mar;351(1):31-6

Effects of enkephalin and 5-hydroxytryptamine on solitary tract neurones involved in respiration and respiratory reflexes. Sessle BJ, et al. **Brain Res** 1985 Feb 18;327(1-2):221-30

Arterial and cardiopulmonary reflexes in the regulation of the neurohumoral drive to the circulation. Bishop VS, et al. **Fed Proc** 1985 May;44(8):2377-81 (31 ref.)

Central nervous system opiate and 5-hydroxytryptamine influences on baroreflex control of the coronary circulation. Moore PG, et al. **J Auton Nerv Syst** 1985 Feb-Mar;12(2-3):185-94

Central nervous system 5-hydroxytryptamine and noradrenaline specificity of ear vascular and ventilation reflexes in thermoregulating rabbits. White SW, et al. **J Auton Nerv Syst** 1985 Feb-Mar; 12(2-3):131-44

Kinetics of drug action in disease states. XIII. Effect of dialyzable component(s) of uremic blood on phenobarbital concentrations in rats at onset of loss of righting reflex. Hisaoka M, et al. **J Pharmacol Exp Ther** 1985 Jul;234(1):180-3

Reflex changes in sympatho-adrenal medullary functions in response to various thermal cutaneous stimulations in anesthetized rats. Kurosawa M, et al. **Neurosci Lett** 1985 May 14;56(2):149-54

Effects of glutamate, substance P and eledoisin-related peptide on solitary tract neurones involved in respiration and respiratory reflexes. Henry JL, et al. **Neuroscience** 1985 Mar;14(3):863-73

Effects of neuroleptics on rate and duration of operant versus reflexive licking in rats. Gramling SE, et al. **Pharmacol Biochem Behav** 1985 Apr; 22(4):541-5

Possible involvement of central adrenergic and histaminergic systems in clonidine-induced inhibition of pinna reflex. Singh PP, et al. **Pharmacol Res Commun** 1985 Mar;17(3):261-9

[Role of hypothalamic adrenoreactive structures in regulating the protective reaction to plasmin] Kalishevskaia TM, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):418-21 (Eng. Abstr.) **(Rus)**

[Analysis of the factors affecting cardiac output in exclusion of the sino-carotid reflexogenic area] Osadchiĭ LI, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):500-5 (Eng. Abstr.) **(Rus)**

RESERPINE

Effects of reserpine and isoproterenol on elemental distribution in submandibular gland of rat. Müller RM, et al. **Acta Physiol Scand** 1985 Apr;123(4):383-91

The chronically reserpinized rat: decreased glycolytic activity in the submandibular gland. Bardoń A, et al. **Biochem Med** 1985 Feb; 33(1):99-103

Effect of chronic reserpine and desmethylimipramine treatment on CRF-like immunoreactivity of discrete brain areas of rat. Tizabi Y, et al. **Brain Res** 1985 Jun 3;335(2):389-91

Catecholamine hormones and the control of avian salt glands. Wilson JX, et al. **Comp Biochem Physiol [C]** 1985;81(1):77-9

Reserpine toxicosis in a horse. Lloyd KC, et al. **J Am Vet Med Assoc** 1985 May 1;186(9):980-1

Reserpine-induced hypothermia and its reversal by dopamine agonists. Danielson TJ, et al. **Life Sci** 1985 Jul 8;37(1):31-8

Amphetamine induced release of endogenous dopamine in vitro is not

best copy available

reduced following pretreatment with reserpine. Niddam R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr;329(2):123-7

Effects of lithium in vitro on noradrenaline-induced cyclic AMP accumulation in rat cortical slices after reserpine-induced supersensitivity. Newman ME, et al. **Neuropharmacology** 1985 Apr; 24(4):353-5

Developmental status of sympathetic innervation in relation to calcium accumulation by submandibular gland following reserpine, surgical sympathectomy or cyclocytidine. Schneyer CA, et al. **Proc Soc Exp Biol Med** 1985 Jun;179(2):143-6

Effects of reserpine and adrenal demedullation on brown adipose tissue thermogenesis induced by dl-phenylpropanolamine. Wellman PJ, et al. **Res Commun Chem Pathol Pharmacol** 1985 Feb;47(2):211-20

RUBIDIUM

Stimulus-secretion coupling of parathyroid hormone release: studies of 45Ca and 86Rb fluxes. Wallfelt C, et al. **Acta Physiol Scand** 1985 Jun; 124(2):239-45

Occlusion of Rb+ by detergent-solubilized (Na+ + K+)-ATPase from shark salt glands. Esmann M. **Biochim Biophys Acta** 1985 May 14; 815(2):196-202

Effects of chronic LiCl and RbCl on muricide induced by midbrain raphe lesions in rats. Yamamoto T, et al. **Pharmacol Biochem Behav** 1985 Apr; 22(4):559-63

SCHIZOPHRENIA

Differential response to amphetamine in schizophrenia. Cesarec Z, et al. **Acta Psychiatr Scand** 1985 May;71(5):523-38

Biochemical theories of schizophrenia and depression. Hollister LE. **Ann Acad Med Singapore** 1985 Jan;14(1):76-80

Creatine phosphokinase and schizophrenia in Singapore. Tsoi WF, et al. **Ann Acad Med Singapore** 1985 Jan;14(1):84-6

The interpretation of plasma haloperidol concentrations. Kirch DG, et al. **Arch Gen Psychiatry** 1985 Aug;42(8):838-40

Plasma haloperidol levels: clinical response and fancy mathematics [letter] Van Putten T, et al. **Arch Gen Psychiatry** 1985 Aug;42(8):835-8

Ceruletide for schizophrenia: a double-blind study. Mattes JA, et al. **Biol Psychiatry** 1985 May;20(5):533-8

Platelet alpha-2-adrenergic dysfunction in negative symptom schizophrenia: a preliminary study. Rosen J, et al. **Biol Psychiatry** 1985 May;20(5):539-45

Electroconvulsive therapy and schizophrenia. Van Valkenburg C, et al. **Biol Psychiatry** 1985 Jul;20(7):699-700

Schizophrenia with good and poor outcome. I: Early clinical features, response to neuroleptics and signs of organic dysfunction. Kolakowska T, et al. **Br J Psychiatry** 1985 Mar;146:229-39

Schizophrenia with good and poor outcome. II: Cerebral ventricular size and its clinical significance. Williams AO, et al. **Br J Psychiatry** 1985 Mar;146:239-46

Lipids and apolipoproteins in patients treated with major tranquilizers. Sasaki J, et al. **Clin Pharmacol Ther** 1985 Jun;37(6):684-7

Bioavailability of oral and intramuscular molindone hydrochloride in schizophrenic patients. Zetin M, et al. **Clin Ther** 1985;7(2):169-75

Platelet monoamine-oxidase activity in schizophrenia. Relation to genetic load of the illness and treatment with antipsychotic drugs. Kemali D, et al. **Encephale** 1985 Jan-Feb;11(1):31-4

Abnormal phosphatidylinositol-cycle of platelet membrane in schizophrenia--a preliminary study. Kaiya H, et al. **Folia Psychiatr Neurol Jpn** 1984;38(4):437-44

Positron emission tomography in schizophrenic patients with and without neuroleptic medication. DeLisi LE, et al. **J Cereb Blood Flow Metab** 1985 Jun;5(2):201-6

Drugs and the quality of life: the patient's point of view. Diamond R. **J Clin Psychiatry** 1985 May;46(5 Pt 2):29-35

Serum neuroleptic levels and clinical outcome in schizophrenic patients treated with fluphenazine decanoate. Brown WA, et al. **J Clin Psychopharmacol** 1985 Jun;5(3):143-7

Problems in classification of schizophrenics as neuroleptic responders and nonresponders. Csernansky JG, et al. **J Nerv Ment Dis** 1985 Jun; 173(6):325-31 (93 ref.)

Lower CSF level of dynorphin(1-8) immunoreactivity in schizophrenic patients. Zhang AZ, et al. **Neuropeptides** 1985 Feb;5(4-6):553-6

State of adrenergic and cholinergic systems in schizophrenia patients during psychopharmacotherapy. Krupenina LB, et al. **Neurosci Behav Physiol** 1985 Jan-Feb;15(1):1-8

One-year outcome of schizophrenic patients--the interaction of chronicity and neuroleptic treatment. Gaebel W, et al. **Pharmacopsychiatry** 1985 May;18(3):235-9

Double-blind comparison of haloperidol decanoate and fluphenazine decanoate effectiveness, side-effects, dosage and serum levels during a six months' treatment for relapse prevention. Kissling W, et al. **Pharmacopsychiatry** 1985 May;18(3):240-5

Serum and cerebrospinal fluid prolactin patterns during neuroleptic treatment in schizophrenic patients. Rimón R, et al. **Pharmacopsychiatry** 1985 May;18(3):252-4

Cerebrospinal fluid cholecystokinin, bombesin and somatostatin in schizophrenia and normals. Gerner RH, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(1):73-82

Delta-sleep inducing peptide in cerebrospinal fluid from schizophrenics, depressives and healthy volunteers. Lindström LH, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(1):83-90

Binding of 3H-spiperone to human lymphocytes: a biological marker in schizophrenia? Bondy B, et al. **Psychiatry Res** 1985 May;15(1):41-8

Serotonin and schizophrenia: correlations between serotonergic activity and schizophrenic motor behavior. King R, et al. **Psychiatry Res** 1985 Mar;14(3):235-40

Lateral ventricular enlargement and clinical response in schizophrenia. Smith RC, et al. **Psychiatry Res** 1985 Mar;14(3):241-53

Amphetamine response and relapse risk after depot neuroleptic discontinuation. Angrist B, et al. **Psychopharmacology (Berlin)** 1985; 85(3):277-83

A limiting factor in the 'normalization' of schizophrenic orienting response dysfunction. Bernstein AS, et al. **Schizophr Bull** 1985;11(2):230-54

Akinesia, tardive dysmentia, and frontal lobe disorder in schizophrenia. Goldberg E. **Schizophr Bull** 1985;11(2):255-63

[Treatment of schizophrenia without symptoms with viloxazine (letter)] Kornhuber HH, et al. **Dtsch Med Wochenschr** 1985 Apr 26; 110(17):698 **(Ger)**

[Social integration of long-term paraphrenic patients with low-dose depot neuroleptic medication] Lesch OM, et al. **Psychiatr Prax** 1985 Mar; 12(2):63-8 (Eng. Abstr.) **(Ger)**

[Neurotransmitters and neuropeptides in schizophrenia] Toru M, et al. **Tanpakushitsu Kakusan Koso** 1984 Dec;29(14):1838-54 (150 ref.) **(Jpn)**

[Asymmetry of cholinesterase activity in cortical centers of human cerebral hemispheres] Kononenko VS, et al. **Fiziol Zh** 1985 Mar-Apr; 31(2):134-8 (Eng. Abstr.) **(Rus)**

SCHIZOPHRENIA, CATATONIC

Treatment-resistant catatonic stupor and combined lithium-neuroleptic therapy: a case report. Climo LH. **J Clin Psychopharmacol** 1985 Jun; 5(3):166-70

SCHIZOPHRENIA, PARANOID

Effects of thioridazine and fluphenazine on the pituitary, thyroid and adrenal functions in patients with paranoid schizophrenia. Horodnicki JM, et al. **Psychiatr Pol** 1984 May-Jun;18(3):205-11

[Haloperidol decanoate in replacing combinations of antipsychotic agents in the treatment of chronic schizophrenics] Yousef HA. **Acta Psiquiatr Psicol Am Lat** 1984 Dec;30(4):297-304 **(Spa)**

SELF STIMULATION

6-OHDA lesions of the ventral tegmental area block morphine-induced but not amphetamine-induced facilitation of self-stimulation. Hand TH, et al. **Brain Res** 1985 Mar 4;328(2):233-41

Comparison of deficits in electrical self-stimulation after ibotenic acid lesion of the lateral hypothalamus and the medial prefrontal cortex. Nassif S, et al. **Brain Res** 1985 Apr 22;332(2):247-57

Lateral hypothalamic self-stimulation persists in rats after destruction of lateral hypothalamic neurons by kainic acid or ibotenic acid. Sprick U, et al. **Neurosci Lett** 1985 May 14;56(2):211-6

Effects of intracranial self-stimulation on brain opioid peptides. Stein EA. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):67-73

Differential effects of pimozide on response-rate and choice accuracy in a self-stimulation paradigm in mice. Bowers W, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):521-6

The discriminative stimulus properties and detection thresholds of intracranial self-stimulation: effects of d-amphetamine, morphine, and haloperidol. Schaefer GJ, et al. **Psychopharmacology (Berlin)** 1985; 85(3):289-94

SEROTONIN

Patency of saphenous veins used for aortocoronary bypass grafting: effects of platelet-derived mediators. Chiavarelli M, et al. **Adv Prostaglandin Thromboxane Leukotriene Res** 1985;13:311-4

The effect of stimulation and blocking of histamine H2 receptors on the turnover of the serotonin in different parts of the alimentary tract and the brain of the rat. Skrzydło-Radomańska B, et al. **Agents Actions** 1985 Apr;16(3-4):183-6

An immunohistochemical study of serotonin development in the opossum cerebellum. Bishop GA, et al. **Anat Embryol (Berl)** 1985; 171(3):325-38

Mediation of storage and retrieval with two drugs that selectively modulate serotonergic neurotransmission. Altman HJ. **Ann NY Acad Sci** 1985;444:496-8

6R-L-erythro-5,6,7,8-tetrahydrobiopterin as a regulator of dopamine and serotonin biosynthesis in the rat brain. Miwa S, et al. **Arch Biochem Biophys** 1985 May 15;239(1):234-41

Effect of amines on fibrinogen synthesis. Roy AK, et al. **Arch Biochem Biophys** 1985 Jun;239(2):364-7

Influence of chronic stellectomy on reactivity to serotonin in the dog external carotid bed. Mena MA, et al. **Arch Int Pharmacodyn Ther** 1985 Jan;273(1):110-6

Human prostatic endocrine-paracrine (APUD) cells. Distributional analysis with a comparison of serotonin and neuron-specific enolase immunoreactivity and silver stains. di Sant'Agnese PA, et al. **Arch Pathol Lab Med** 1985 Jul;109(7):607-12

Differential release of serotonin without comparable histamine under diverse conditions in the rat mast cell. Theoharides TC, et al. **Biochem Pharmacol** 1985 May 1;34(9):1389-98

Endogenous platelet serotonin release monitored during aggregation by means of a new electrochemical technique. Marcenac F, et al. **Biochim Biophys Acta** 1985 Jul 5;840(3):377-82

The distribution and origin of serotonin immunoreactivity in the rat cerebellum. Bishop GA, et al. **Brain Res** 1985 Apr 8;331(2):195-207

Differential responses of serotonergic and non-serotonergic neurons in nucleus raphe magnus to systemic morphine in rats. Chiang CY, et al. **Brain Res** 1985 Jun 24;337(1):146-50

Ontogenetic development of serotoninergic neurons in the brain of a teleost, the three-spined stickleback. An immunohistochemical analysis. Ekström P, et al. **Brain Res** 1985 Jan;349(1-2):209-24

Serotonin depolarizes type A and C primary afferents: an intracellular study in bullfrog dorsal root ganglion. Holz GG, et al. **Brain Res** 1985 Feb 18;327(1-2):71-9

Enhancement of some 5-HT-dependent behavioural responses following repeated immobilization in rats. Kennett GA, et al. **Brain Res** 1985 Mar 25;330(2):253-63

Decreased serotonin content of embryonic raphe neurons following maternal administration of p-chlorophenylalanine: a quantitative immunocytochemical study. Lauder JM, et al. **Brain Res** 1985 May;352(1):107-14

Inhibitory influence of GABA on central serotonergic transmission. Raphe nuclei as the neuroanatomical site of the GABAergic inhibition of cerebral serotonergic neurons. Nishikawa T, et al. **Brain Res** 1985 Apr 1;331(1):91-103

Inhibitory influence of GABA on central serotonergic transmission. Involvement of the habenulo-raphe pathways in the GABAergic inhibition of ascending cerebral serotonergic neurons. Nishikawa T, et al. **Brain Res** 1985 Apr 1;331(1):81-90

Serotonin release in human cerebral cortex and its modulation via serotonin receptors. Schlicker E, et al. **Brain Res** 1985 Apr 8;331(2):337-41

Effects of enkephalin and 5-hydroxytryptamine on solitary tract neurones involved in respiration and respiratory reflexes. Sessle BJ, et al. **Brain Res** 1985 Feb 18;327(1-2):221-30

The distribution of monoaminergic cells and fibers in a periventricular preoptic nucleus involved in the control of gonadotropin release: immunohistochemical evidence for a dopaminergic sexual dimorphism. Simerly RB, et al. **Brain Res** 1985 Mar 18;330(1):55-64

Ontogenetic alterations in the effects of food and/or maternal deprivation on 5-HT, 5-HIAA and 5-HIAA/5-HT ratios. Spear LP, et al. **Brain Res** 1985 Feb;350(1-2):143-57

Characterization of sodium-dependent, high-affinity serotonin uptake in rat spinal cord synaptosomes. Stauderman KA, et al. **Brain Res** 1985 Mar 18;330(1):11-20

Denervation supersensitivity to 5-hydroxytryptamine in the rat spinal cord is not due to the absence of 5-hydroxytryptamine. Tremblay LE, et al. **Brain Res** 1985 Mar 18;330(1):174-7

Immunocytochemical and radioautographic study of serotonin projections to cerebral ventricles of perinatal rats. Ugrumov MV, et al. **Brain Res** 1985 Feb;350(1-2):225-30

A comparison of the effects of serotonin, substance P and thyrotropin-releasing hormone on excitability of rat spinal motoneurons in vivo. White SR. **Brain Res** 1985 May 27;335(1):63-70

Progesterone stimulates sexual behaviour in female rats by increasing 5-HT activity on 5-HT2 receptors. Wilson CA, et al. **Brain Res** 1985 May 6;333(2):223-9

Postnatal development of serotonin in adrenal medullary cells. Holzwarth MA, et al. **Brain Res Bull** 1985 Jan;14(1):15-23

Localization of somatostatin-, bombesin-, and serotonin-like immunoreactivity in the lung of the fetal rhesus monkey. Dayer AM, et al. **Cell Tissue Res** 1985;239(3):621-5

Immunocytochemical demonstration of neuropeptides and serotonin in the tapeworm Diphyllobothrium dendriticum. Gustafsson MK, et al. **Cell Tissue Res** 1985;240(2):255-60

Immunocytochemical localization of serotonin in the brain and pituitary gland of the platyfish, Xiphophorus maculatus. Margolis-Kazan H, et al. **Cell Tissue Res** 1985;240(2):311-4

Unsaturated 1-O-alkyl-2-acetyl-sn-glycero-3-phosphocholines (unsaturated platelet-activating factor): aggregation of human platelets after incubation with indomethacin, creatinephosphate/creatinephosphokinase, xylocain and hirudine, and serotonin release after incubation with indomethacin. Korth R, et al. **Chem Phys Lipids** 1985 Jan;36(3):209-14

Removal of the endothelium potentiates canine large coronary artery constrictor responses to 5-hydroxytryptamine in vivo. Lamping KG, et al. **Circ Res** 1985 Jul;57(1):46-54

Liquid chromatography of serotonin and adenine nucleotides in blood platelets, illustrated by evaluation of functional integrity of platelet preparations. Ingebretsen OC, et al. **Clin Chem** 1985 May;31(5):695-8

Further studies on the effects of adrenal steroids in the active transport of serotonin into rat platelets. Lee PH, et al. **Clin Exp Pharmacol Physiol** 1985 Jan-Feb;12(1):43-50

Intraplatelet serotonin (I5HT) in children with the hemolytic uremic syndrome. Edefonti A, et al. **Clin Nephrol** 1985 Apr;23(4):207-11

A molecular theory of recognition and activation at a 5-HT receptor based on a quantum chemical approach to structure activity relationships. Osman R, et al. **Clin Physiol Biochem** 1985;3(2-3):80-8

The influence of testosterone in the brain of the male rat on levels of serotonin (5-HT) and hydroxyindole-acetic acid (5-HIAA). Martinez-Conde E, et al. **Comp Biochem Physiol** [C] 1985;80(2):411-4

The uptake and metabolism of 5-hydroxytryptamine by tissue slices of the cestode Hymenolepis diminuta. Webb RA. **Comp Biochem Physiol** [C] 1985;80(2):305-12

Trials of serotonin, substance P and alpha 2-adrenergic receptor effects on the equine large colon. Sellers AF, et al. **Cornell Vet** 1985 Apr;75(2):319-23

Scheduled feeding and 24-hour rhythms of N-acetylserotonin and melatonin in rats. Ho AK, et al. **Endocrinology** 1985 May;116(5):1858-62

Serotonergic elements of the mammalian pituitary. Payette RF, et al. **Endocrinology** 1985 May;116(5):1933-42

An investigation of amphetamine-induced release of 5-HT from rat hippocampal slices. Balfour DJ, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):395-9

Age-related changes in 5HT uptake and [3H]imipramine binding sites in rat cerebral cortex. Brunello N, et al. **Eur J Pharmacol** 1985 Apr 16;110(3):393-4

Inhibition by antiserum to vasoactive intestinal polypeptide (VIP) of prolactin secretion induced by serotonin in the rat. Ohta H, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):409-12

Physostigmine effects on serotonin uptake in human blood platelets. Rausch JL, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):91-6

Does brain 5-HIAA indicate serotonin release or monoamine oxidase activity? Wolf WA, et al. **Eur J Pharmacol** 1985 Mar 12;109(3):381-7

Activity of serotonin-containing neurons in nucleus raphe magnus in freely moving cats. Fornal C, et al. **Exp Neurol** 1985 Jun;88(3):590-608

The enteric neural receptor for 5-hydroxytryptamine. Gershon MD, et al. **Experientia** 1985 Jul 15;41(7):863-8

Effect of various excitatory agonists on the secretion of 5-hydroxytryptamine from permeabilised human platelets induced by Ca2+ in the presence or absence of GTP. Knight DE, et al. **FEBS Lett** 1985 Apr 22;183(2):417-22

Endothelial serotonin uptake and mediation of prostanoid secretion and stress fiber formation. Shepro D, et al. **Fed Proc** 1985 Jul;44(10):2616-9

Evidence for negative feedback control of the release of [3H]serotonin from superfused mouse cerebellum slices induced by electrical field stimulation. Figueroa HR, et al. **Gen Pharmacol** 1985;16(2):103-8

Subcellular localization of serotonin immunoreactivity in rat enterochromaffin cells. Nilsson O, et al. **Histochemistry** 1985;82(4):351-5

Immunohistological studies of masked indoleamine cells in the area postrema of the rat. Nishida K, et al. **Histochemistry** 1985;82(2):101-6

Role of 5-HT on increased permeability of blood-brain barrier under heat stress. Sharma HS, et al. **Indian J Physiol Pharmacol** 1984 Oct-Dec;28(4):259-67

Cloned mouse mast cells and normal mouse peritoneal mast cells. Determination of serotonin content and ability to synthesize serotonin in vitro. Weitzman G, et al. **Int Arch Allergy Appl Immunol** 1985;77(1-2):189-91

Pharmacologic studies of the central action of zopiclone: effects on locomotor activity and brain monoamines in rats. Liu HJ, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Mar;23(3):121-8

Effects of pinealectomy on regional brain serotonin metabolism. Aldegunde M, et al. **Int J Neurosci** 1985 Apr;26(1-2):9-13

d-Fenfluramine and salbutamol: two drugs causing anorexia through different neurochemical mechanisms. Garattini S, et al. **Int J Obes** 1984;8 Suppl 1:151-7

Two novel agents affecting eating through an action on monoaminergic systems. Roncucci R, et al. **Int J Obes** 1984;8 Suppl 1:103-17

Serotonin relationships of autistic probands and their first-degree relatives. Kuperman S, et al. **J Am Acad Child Psychiatry** 1985 Mar;24(2):186-90

Central nervous system opiate and 5-hydroxytryptamine influences on baroreflex control of the coronary circulation. Moore PG, et al. **J Auton Nerv Syst** 1985 Feb–Mar;12(2–3):185–94

Role of central nervous system monoamines in cardiopulmonary effects of Althesin in rabbit and man. Quail AW, et al. **J Auton Nerv Syst** 1985 Feb–Mar;12(2–3):159–74

Central nervous system 5–hydroxytryptamine and noradrenaline specificity of ear vascular and ventilation reflexes in thermoregulating rabbits. White SW, et al. **J Auton Nerv Syst** 1985 Feb–Mar; 12(2–3):131–44

Evidence that phospholipid turnover is the signal transducing system coupled to serotonin–S2 receptor sites. de Chaffoy de Courcelles D, et al. **J Biol Chem** 1985 Jun 25;260(12):7603–8

Thrombin induces serotonin secretion and aggregation independently of inositol phospholipids hydrolysis and protein phosphorylation in human platelets permeabilized with saponin. Lapetina EG, et al. **J Biol Chem** 1985 Jun 10;260(11):7078–83

5–Hydroxytryptamine stimulates inositol phosphate production in a cell–free system from blowfly salivary glands. Evidence for a role of GTP in coupling receptor activation to phosphoinositide breakdown. Litosch I, et al. **J Biol Chem** 1985 May 10;260(9):5464–71

Vasoactive amines modulate actin cables (stress fibers) and surface area in cultured bovine endothelium. Welles SL, et al. **J Cell Physiol** 1985 Jun;123(3):337–42

Nimodipine has an inhibitory action on neurotransmitter release from human cerebral arteries. Porter JD, et al. **J Cereb Blood Flow Metab** 1985 Jun;5(2):338–42

Localization of serotonin immunoreactivity in the opossum cerebellum. Bishop GA, et al. **J Comp Neurol** 1985 May 15;235(3):301–21

Possible target neurons of 5–hydroxytryptamine fibers in the lamprey spinal cord: immunohistochemistry combined with intracellular staining with Lucifer yellow. Van Dongen PA, et al. **J Comp Neurol** 1985 Apr 22;234(4):523–35

Serotoninlike immunoreactivity in the cestode Hymenolepis diminuta. Webb RA, et al. **J Comp Neurol** 1985 Apr 22;234(4):431–40

Ultrastructural analysis of central serotoninergic neurons immunolabeled by silver–gold–intensified diaminobenzidine chromogen. Completion of immunocytochemistry with X–ray microanalysis. Liposits Z, et al. **J Histochem Cytochem** 1985 Jun;33(6):604–10

Sprouting and functional regeneration of an identified serotonergic neuron following axotomy. Murphy AD, et al. **J Neurobiol** 1985 Mar; 16(2):137–51

3,4–Dihydroxyphenylethylamine and 5–hydroxytryptamine metabolism in the rat: acidic metabolites in cisternal cerebrospinal fluid before and after giving probenecid. Curzon G, et al. **J Neurochem** 1985 Aug; 45(2):508–13

Neurochemical profile of Lu 19–005, a potent inhibitor of uptake of dopamine, noradrenaline, and serotonin. Hyttel J, et al. **J Neurochem** 1985 May;44(5):1615–22

Tryptamine concentrations in areas of 5–hydroxytryptamine terminal innervation after electrolytic lesions of midbrain raphe nuclei. Juorio AV, et al. **J Neurochem** 1985 Aug;45(2):422–6

Assessment of noradrenaline and 5–hydroxytryptamine uptake in intact rat brain. Wyllie MG, et al. **J Neurochem** 1985 Aug;45(2):456–60

Localization of 5–hydroxytryptamine to neurons and endoneurial mast cells in rat sensory ganglia. Kai–Kai MA, et al. **J Neurocytol** 1985 Feb; 14(1):63–78

Preparation and characterization of antisera and monoclonal antibodies to serotonergic and dopaminergic ligands. Flurkey K, et al. **J Neuroimmunol** 1985 May;8(2–3):115–27

Effect of prostaglandin F2 alpha on brain and stomach 5–hydroxytryptamine. Sanyal AK, et al. **J Pharm Pharmacol** 1985 Apr; 37(4):274–5

5–Hydroxytryptamine–stimulated inositol phospholipid hydrolysis in rat cerebral cortex slices: pharmacological characterization and effects of antidepressants. Kendall DA, et al. **J Pharmacol Exp Ther** 1985 May; 233(2):473–9

Efflux of 5–hydroxytryptamine and noradrenaline into spinal cord superfusates during stimulation of the rat medulla. Hammond DL, et al. **J Physiol (Lond)** 1985 Feb;359:151–62

A calcium–dependent reversible permeability increase in microvessels in frog brain, induced by serotonin. Olesen SP. **J Physiol (Lond)** 1985 Apr;361:103–13

In vivo electrochemical studies of rat striatal dopamine and serotonin release after morphine. Broderick PA. **Life Sci** 1985 Jun 17; 36(24):2269–75

Differential effects of isoproterenol injections on the levels of pineal N–acetyltransferase, serum N–acetylserotonin and melatonin. Ho AK, et al. **Life Sci** 1985 Jun 3;36(22):2137–43

Differential regulation of the brain and gut immunoreactive dynorphin by the serotonin system. Majeed NH, et al. **Life Sci** 1985 Jul 29; 37(4):339–43

The effect of epinephrine and serotonin on hepatic poly(A)+ RNA synthesis. Roy AK, et al. **Life Sci** 1985 Jun 17;36(24):2301–7

Development of selective tolerance to the serotonin behavioral syndrome and suppression of locomotor activity after repeated administration of either 5–MeODMT or mCPP. Sills MA, et al. **Life Sci** 1985 Jul 1; 36(26):2463–9

Modulation of a transient outward current in serotonergic neurones by alpha 1–adrenoceptors. Aghajanian GK. **Nature** 1985 Jun 6–12; 315(6019):501–3

The depolarizing action of 5–hydroxytryptamine on rabbit vagal primary afferent and sympathetic neurones and its selective blockade by MDL 72222. Azami J, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb; 328(4):423–9

Effect of triamterene on 5–hydroxytryptamine biosynthesis in different brain areas. Steinberg P, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Mar;329(1):42–4

Role of the serotonin uptake carrier in the neurochemical response to methamphetamine: effects of citalopram and chlorimipramine. Schmidt CJ, et al. **Neurochem Res** 1985 May;10(5):637–48

The uptake of serotonin and dopamine by homogenates of frozen rat and human brain tissue. Stenström A, et al. **Neurochem Res** 1985 May; 10(5):591–9

Opiate regulation of mesolimbic serotonin release: in vivo semiderivative electrochemical analyses. Broderick PA. **Neuropeptides** 1985 Feb; 5(4–6):587–90

Differential modulation of the beta–endorphin and dynorphin systems by serotonergic stimulation in the rat. Majeed NH, et al. **Neuropeptides** 1985 Feb;5(4–6):563–6

Serotonin and antidepressant drugs antagonize melatonin–induced behavioural changes after injection into the nucleus accumbens of rats. Gaffori O, et al. **Neuropharmacology** 1985 Mar;24(3):237–44

Down–regulation of beta–adrenoceptors in rat cortex by repeated administration of desipramine, electroconvulsive shock and clenbuterol requires 5–HT neurones but not 5–HT. Nimgaonkar VL, et al. **Neuropharmacology** 1985 Apr;24(4):279–83

The effect of prolonged treatment with tricyclic antidepressants on the actions of 5–hydroxytryptamine in the hippocampal slice of the rat. Rowan MJ, et al. **Neuropharmacology** 1985 Feb;24(2):131–7

Morphological evidence that serotonin–immunoreactive neurons in the nucleus dorsomedialis hypothalami could be under catecholaminergic influence. Arezki F, et al. **Neurosci Lett** 1985 May 14;56(2):161–6

Immunohistochemical and biochemical detection of serotonin in the guinea pig celiac–superior mesenteric plexus. Ma RC, et al. **Neurosci Lett** 1985 May 14;56(2):107–12

Membrane responses and changes in cAMP levels in Aplysia sensory neurons produced by serotonin, tryptamine, FMRFamide and small cardioactive peptideB (SCPB). Ocorr KA, et al. **Neurosci Lett** 1985 Apr 9;55(2):113–8

The effect of adrenalectomy and corticosterone on homotypic collateral sprouting of serotonergic fibers in hippocampus. Zhou FC, et al. **Neurosci Lett** 1985 Mar 15;54(2–3):111–6

Distribution of serotonergic neurons and processes in the lamprey spinal cord. Harris–Warrick RM, et al. **Neuroscience** 1985 Apr; 14(4):1127–40

A serotonin–containing pathway from the area postrema to the parabrachial nucleus in the rat. Lança AJ, et al. **Neuroscience** 1985 Apr; 14(4):1117–26

Serotonergic terminals in the neural sheath of the blowfly nervous system: electron microscopical immunocytochemistry and 5,7–dihydroxytryptamine labelling. Nässel DR, et al. **Neuroscience** 1985 May;15(1):293–307

Altered responses to serotonergic agents in Fawn–Hooded rats. Gudelsky GA, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):489–92

Involvement of the serotonergic system in the prolongation of pentobarbital sleeping time produced by prostaglandin D2. Hollingsworth EB, et al. **Pharmacol Biochem Behav** 1985 Mar; 22(3):365–70

The effects produced by prostaglandin D2 on serotonin turnover and release and tryptophan uptake. Hollingsworth EB, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):371–5

Manipulations of 5–HT activity and memory in the rat. Lalonde R, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):377–82

Effects of quipazine and methysergide on play in juvenile rats. Normansell L, et al. **Pharmacol Biochem Behav** 1985 May;22(5):885–7

Suppression of male copulatory behavior by delta 9–THC is not dependent on changes in plasma testosterone or hypothalamic dopamine or serotonin content. Shrenker P, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):415–20

Increased sensitivity to serotonergic agonists after repeated electroconvulsive shock in rats. Wielosz M. **Pharmacol Biochem Behav** 1985 May;22(5):683–7

Some behavioral effects of microinjections of serotonin and noradrenaline into the limbic structures of the rat brain. Plaźnik A. **Pol J Pharmacol Pharm** 1984 Sep–Oct;36(5):541–54

Serotonergic control of experimental aggression. Valzelli L, et al. **Pol J Pharmacol Pharm** 1984 Sep–Oct;36(5):495–503

Combined lithium and valproate treatment and subsequent withdrawal: serotonergic mechanism of their interaction in discrete brain regions. Shukla GS. **Prog Neuropsychopharmacol Biol Psychiatry** 1985; 9(2):153–6

Serotonin and schizophrenia: correlations between serotonergic activity and schizophrenic motor behavior. King R, et al. **Psychiatry Res** 1985 Mar;14(3):235-40

Anti-aversive role of serotonin in the dorsal periaqueductal grey matter. Schütz MT, et al. **Psychopharmacology (Berlin)** 1985;85(3):340-5

Inhibition of platelet function by contrast media: iopamidol and ioxaglate versus iothalamate. Work in progress. Rao AK, et al. **Radiology** 1985 Aug;156(2):311-3

Up-regulation of thyrotropin-releasing hormone (TRH) receptors in rat spinal cord after codepletion of serotonin and TRH. Ogawa N, et al. **Regul Pept** 1985 Mar;10(2-3):85-90

High-performance liquid chromatographic assay of serotonin in human plasma. Marasini B, et al. **Ric Clin Lab** 1985 Jan-Mar;15(1):63-9

The effects of vagal nerve stimulation on endoluminal release of serotonin and substance P into the feline small intestine. Grønstad KO, et al. **Scand J Gastroenterol** 1985 Mar;20(2):163-9

High-affinity uptake of serotonin into immunocytochemically identified astrocytes. Kimelberg HK, et al. **Science** 1985 May 17; 228(4701):889-91

Diurnal rhythms of N-acetylserotonin and serotonin in cerebrospinal fluid of monkeys. Taylor PA, et al. **Science** 1985 May 17;228(4701):900

Serotonin-induced platelet aggregation in whole blood and the effects of ketanserin and mepyramine. Bevan J, et al. **Thromb Res** 1985 Apr 15;38(2):189-94

Platelet-mediated vascular permeability in the rat: a predominant role for 5-hydroxytryptamine. De Clerck F, et al. **Thromb Res** 1985 May 15;38(4):321-39

[Stimulatory control by oxytocin (or an analog peptide) of the pituitary intermediate lobe in rabbits. Inhibitory role of serotonin] Schimchowitsch S, et al. **C R Acad Sci [III]** 1985;300(7):283-6 (Eng. Abstr.) **(Fre)**

[Classification of chronic psychoses types I and II and platelet serotonin levels. Apropos of 38 cases] Boudjema F, et al. **Encephale** 1985 Jan-Feb; 11(1):39-42 (Eng. Abstr.) **(Fre)**

[Central serotonin receptors] Fillion G. **Pathol Biol (Paris)** 1985 Apr; 33(4):221-6 (56 ref.) **(Fre)**

[Preliminary observations on the distribution of serotoninergic and cerebellar-projecting neurons of the raphe nuclei of the brain stem] De Leo F, et al. **Boll Soc Ital Biol Sper** 1985 Feb 28;61(2):229-33 (Eng. Abstr.) **(Ita)**

[Structure of the binding center of the serotonin S2 receptor] Kats MM. **Biol Nauki** 1985;(3):19-24 (Eng. Abstr.) **(Rus)**

[pH changes in the matrix of serotonin organelles of stimulated thrombocytes] Kozlov VK, et al. **Biull Vsesoiuznogo Kardiol Nauchn Tsentra AMN SSSR** 1985; 8(1):77-82 (Eng. Abstr.) **(Rus)**

[Effect of cold on the brain serotonin system and the corticosteroid level of the blood in different strains of mice] Koriakina LA, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):422-7 (Eng. Abstr.) **(Rus)**

SEX BEHAVIOR, ANIMAL

The proestrous surge of prolactin enhances sexual receptivity in the rat. Witcher JA, et al. **Biol Reprod** 1985 May;32(4):834-9

Modulation of lordosis behaviour in the female rat by corticotropin releasing factor, beta-endorphin and gonadotropin releasing hormone in the mesencephalic central gray. Sirinathsinghji DJ. **Brain Res** 1985 Jun 10;336(1):45-55

Progesterone stimulates sexual behaviour in female rats by increasing 5-HT activity on 5-HT2 receptors. Wilson CA, et al. **Brain Res** 1985 May 6;333(2):223-9

Antagonism by lisuride and 8-OH-DPAT of 5-HTP-induced prolongation of the performance of male rat sexual behavior. Ahlenius S, et al. **Eur J Pharmacol** 1985 Apr 16;110(3):379-81

The dopamine autoreceptor agonist B-HT 920 markedly stimulates sexual behavior in male rats. Ferrari F, et al. **Experientia** 1985 May 15; 41(5):636-8

Changes in hormone levels in relation to breeding behavior in male bullfrogs (Rana catesbeiana) at the individual and population levels. Mendonça MT, et al. **Gen Comp Endocrinol** 1985 May;58(2):270-9

Adrenalectomy does not prevent the hyperprolactinemic, induced sexual behavior deficits in CDF male rats. Shrenker P, et al. **Life Sci** 1985 May 13;36(19):1881-8

Neuroendocrine regulation of seasonal reproductive activity in the male golden hamster. Steger RW, et al. **Neurosci Biobehav Rev** 1985 Summer; 9(2):191-201

Potentiative action of alpha- and beta-adrenergic receptor stimulation in inducing lordosis behavior. Fernández-Guasti A, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):613-7

Serotonin antagonist pirenperone inhibits sexual behavior in the male rat: attenuation by quipazine. Mendelson SD, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):565-71

Suppression of male copulatory behavior by delta 9-THC is not dependent on changes in plasma testosterone or hypothalamic dopamine or serotonin content. Shrenker P, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):415-20

SHARED PARANOID DISORDER

A relapsing folie à trois. Fernando FP, et al. **Br J Psychiatry** 1985 Mar; 146:315-6

SLEEP

Effects of doxylamine and acetaminophen on postoperative sleep. Smith GM, et al. **Clin Pharmacol Ther** 1985 May;37(5):549-57

Beta 1 and beta 2 adrenergic receptors: their role in the regulation of paradoxical sleep in the rat. Lanfumey L, et al. **Electroencephalogr Clin Neurophysiol** 1985 Jun;60(6):558-67

Sedation and sleep induced by high doses of apomorphine after blockade of D-1 receptors by SCH 23390. Gessa GL, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):269-74

Effects of exhaustive submaximal exercise on cardiovascular function during sleep. Bunnell DE, et al. **J Appl Physiol** 1985 Jun; 58(6):1909-13

Auto-tolerance to the endogenous opioids and sleep. Gillman MA, et al. **Med Hypotheses** 1985 Apr;16(4):393-5

Effects of acute and chronic treatment with amitryptyline on the sleep-wake activity of rats. Obál F Jr, et al. **Neuropharmacology** 1985 Mar;24(3):223-9

p-Chloroamphetamine: effect on sleep and respiration in the rat. DeMesquita S. **Pharmacol Biochem Behav** 1985 May;22(5):889-91

Involvement of the serotonergic system in the prolongation of pentobarbital sleeping time produced by prostaglandin D2. Hollingsworth EB, et al. **Pharmacol Biochem Behav** 1985 Mar; 22(3):365-70

SLEEP DEPRIVATION

Can lithium carbonate prolong the antidepressant effect of sleep deprivation? [letter] Baxter LR Jr. **Arch Gen Psychiatry** 1985 Jun; 42(6):635

Paradoxical sleep deprivation and the immobility response in the rat: effects of desipramine and phentolamine. van Luijtelaar EL, et al. **Sleep** 1985;8(1):49-55

[Sleep deprivation as a method of treating endogenous depression] Vovin RIa, et al. **Zh Nevropatol Psikhiatr** 1985;85(4):560-5 (Eng. Abstr.) **(Rus)**

SLEEP, REM

Internight variability of REM latency in major depression: implications for the use of REM latency as a biological correlate. Ansseau M, et al. **Biol Psychiatry** 1985 May;20(5):489-505

Cholinomimetic drug RS 86, REM sleep, and depression [letter] Berger M, et al. **Lancet** 1985 Jun 15;1(8442):1385-6

Paradoxical sleep deprivation and the immobility response in the rat: effects of desipramine and phentolamine. van Luijtelaar EL, et al. **Sleep** 1985;8(1):49-55

SLEEP STAGES

Prenatal exposure to diazepam results in enduring reductions in brain receptors and deep slow wave sleep. Livezey GT, et al. **Brain Res** 1985 May 20;334(2):361-5

Relationship between sleep efficiency and urinary excretion of catecholamines in bed-rested humans. Nishihara K, et al. **Sleep** 1985; 8(2):110-7

SOCIAL ADJUSTMENT

Treatment characteristics of psychiatric programs that correlate with patient community adjustment. Collins JF, et al. **J Clin Psychol** 1985 May;41(3):299-308

[Social integration of long-term paraphrenic patients with low-dose depot neuroleptic medication] Lesch OM, et al. **Psychiatr Prax** 1985 Mar; 12(2):63-8 (Eng. Abstr.) **(Ger)**

SODIUM

Human platelet alpha 2-adrenergic receptors: effect of Na^+ on interaction with the adenylate cyclase system and on epinephrine-stimulated platelet secretion. Limbird LE, et al. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:235-42

Studies on role of calmodulin in Ca^{2+} regulation of rabbit ileal Na and Cl transport. Donowitz M, et al. **Am J Physiol** 1985 Jun; 248(6 Pt 1):G726-40

Central effects of angiotensin II and dopamine in sodium-depleted sheep. Huang BS, et al. **Am J Physiol** 1985 May;248(5 Pt 2):R541-8

Mineralocorticoid regulation of apical cell membrane Na^+ and K^+ transport of the cortical collecting duct. Sansom SC, et al. **Am J Physiol** 1985 Jun;248(6 Pt 2):F858-68

A novel technique for assessing the sources of dietary sodium. Sanchez-Castillo CP, et al. **Ann Clin Res** 1984;16 Suppl 43:44-8

Inhibition of Na^+/Ca^{2+} exchange in pituitary plasma membrane vesicles by analogues of amiloride. Kaczorowski GJ, et al. **Biochemistry** 1985 Mar 12;24(6):1394–403

Coupling of a loop diuretic-sensitive Na+ influx with the net loop diuretic-sensitive K+ efflux in mouse NIH 3T3 cells. Panet R, et al. **Biochim Biophys Acta** 1985 Jun 27;816(2):278–82

The effect of the intracellular sodium level on the activity of amino acid transport systems L and A in SV40 3T3 cells. Petronini PG, et al. **Biochim Biophys Acta** 1985 May 28;815(3):361–8

Characterization of sodium-dependent, high-affinity serotonin uptake in rat spinal cord synaptosomes. Stauderman KA, et al. **Brain Res** 1985 Mar 18;330(1):11–20

Study of the interrelationship between dopaminergic activity and potassium ion. Matsuda S, et al. **Clin Exp Hypertens [A]** 1984; 6(12):2249–61

The influence of the membrane sodium pump activity on the ability of human peripheral blood lymphocytes to form early rosettes with SRBC. Witkowski J. **Immunology** 1985 Jun;55(2):339–45

Localization of potassium and sodium fluxes in the rat lens. Reszelbach R, et al. **Invest Ophthalmol Vis Sci** 1985 Jul;26(7):945–52

Evidence for tyrosyl residues at the Na+ site on the intestinal Na+/glucose cotransporter. Peerce BE, et al. **J Biol Chem** 1985 May 25;260(10):6026–31

Na+ (Li+)-proline cotransport in Escherichia coli. Chen CC, et al. **J Membr Biol** 1985;84(2):157–64

Sodium-dependent modulation of the renal Na-K-ATPase: influence of mineralocorticoids on the cortical collecting duct. O'Neil RG, et al. **J Membr Biol** 1985;85(2):169–79

Influence of lead ions on cation permeability in human red cell ghosts. Simons TJ. **J Membr Biol** 1985;84(1):61–71

GABAergic inhibition of hypertonic saline-induced vasopressin-dependent hypertension. Brennan TJ, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):663–71

Effects of angiotensin or carbachol on sodium intake and excretion in adrenalectomized or deoxycorticosterone-treated rats. Fitzsimons JT, et al. **J Physiol (Lond)** 1985 Feb;359:447–58

Cation activation of the pig kidney sodium pump: transmembrane allosteric effects of sodium. Karlish SJ, et al. **J Physiol (Lond)** 1985 Feb;359:119–49

Inhibition of sodium transport in frog skin and iodination of tyrosine in vitro by a peptide of renal origin. Fregly MJ, et al. **Klin Wochenschr** 1985;63 Suppl 3:102–6

The relation of sodium transport to blood pressure in the adrenalectomized rat. Friedman SM. **Klin Wochenschr** 1985;63 Suppl 3:55–8

Modulation of erythrocyte Na transport pathway(s) by excess Na intake. Dagher G, et al. **Life Sci** 1985 Jul 22;37(3):243–53

Intracellular Ca indicator Quin-2 inhibits Ca2+ inflow via Na/Ca exchange in squid axon. Allen TJ, et al. **Nature** 1985 Jun 27–Jul 3; 315(6022):755–6

The effect of phenylalanine on intracellular pH and sodium activity in proximal convoluted tubule cells of the frog kidney. Messner G, et al. **Pflugers Arch** 1985 May;404(2):145–9

Behaviour of chemically modified sodium channels in frog nerve supports a three-state model of inactivation. Schmidtmayer J. **Pflugers Arch** 1985 May;404(1):21–8

Effect of a low sodium medium, ouabain and noradrenaline on relaxation of the myocardium of the perfused rabbit heart. Fišer B, et al. **Physiol Bohemoslov** 1985;34(1):77–84

Effect of dialysate sodium on the dopamine, adrenaline and noradrenaline concentration in haemodialysis patients. Ksiażek A, et al. **Proc Eur Dial Transplant Assoc Eur Ren Assoc** 1985;21:225–9

Study of the ionic basis of visual transduction in vertebrate retinal rods. Yau KW, et al. **Prog Clin Biol Res** 1985;176:21–31 (36 ref.)

[Possible participation of slow Na+--Ca++ channels in realizing cholinergic effects on the cardiac pacemaker] Sukhova GS, et al. **Fiziol Zh SSSR** 1985 Apr;71(4):506–9 (Eng. Abstr.) **(Rus)**

SOMATOSTATIN

Somatostatin inhibition of cyclic AMP accumulation and adrenocorticotropin release from mouse anterior pituitary tumor cells: mode of action and self-regulation. Reisine TD. **Adv Cyclic Nucleotide Protein Phosphorylation Res** 1985;19:169–77

Cholecystokinin potently releases somatostatin from canine fundic mucosal cells in short-term culture. Soll AH, et al. **Am J Physiol** 1985 May;248(5 Pt 1):G569–73

The somatostatin-28 convertase of rat brain cortex generates both somatostatin-14 and somatostatin-28. Gluschankof P, et al. **Biochem Biophys Res Commun** 1985 May 16;128(3):1051–7

Effect of somatostatin on the proliferation of mouse spleen lymphocytes in vitro. Pawlikowski M, et al. **Biochem Biophys Res Commun** 1985 May 31;129(1):52–5

Difference in dose-response curves for glucose-induced insulin and somatostatin release in rat pancreas. Dettori-Gera C, et al. **Biochim Biophys Acta** 1985 May 8;839(3):281–6

The biological activity of duck 'big' somatostatin on chicken adipose tissue. Di Scala-Guenot D, et al. **Biochim Biophys Acta** 1985 May 30; 845(2):261–4

Immunocytochemical localization of somatostatin and cholecystokinin in the cat visual cortex. Demeulemeester H, et al. **Brain Res** 1985 Apr 22;332(2):361–4

Immunocytochemical localization of somatostatin-28 in the rat hypothalamus. Guy J, et al. **Brain Res** 1985 Mar 25;330(2):283–9

Thyroid hormones reversibly suppress somatostatin secretion and immunoreactivity in cultured neocortical cells. Peterfreund RA, et al. **Brain Res** 1985 Mar 4;328(2):259–70

The effects of neurotensin, vasoactive intestinal polypeptide and other neuropeptides on the secretion of somatostatin from cerebral cortical cells. Robbins RJ, et al. **Brain Res** 1985 Apr 15;332(1):161–4

Vasoactive intestinal peptide and PHI stimulate somatostatin release from rat cerebral cortical and diencephalic cells in dispersed cell culture. Tapia-Arancibia L, et al. **Brain Res** 1985 Jun 10;336(1):67–72

Comparison of somatostatin-28 and somatostatin-14 clearance by the perfused rat liver. Seno M, et al. **Can J Physiol Pharmacol** 1985 Jan; 63(1):62–7

Tissue-specific posttranslational processing of pre-prosomatostatin encoded by a metallothionein-somatostatin fusion gene in transgenic mice. Low MJ, et al. **Cell** 1985 May;41(1):211–9

Localization of somatostatin-, bombesin-, and serotonin-like immunoreactivity in the lung of the fetal rhesus monkey. Dayer AM, et al. **Cell Tissue Res** 1985;239(3):621–5

Somatostatin-14 modulates postprandial glucose levels and release of gastrointestinal and pancreatic hormones. O'Shaughnessy DJ, et al. **Digestion** 1985;31(4):234–42

Characterization of tissue and releasable molecular forms of somatostatin-28[1–12]-like immunoreactivity in rat median eminence. Charpenet G, et al. **Endocrinology** 1985 May;116(5):1863–8

Somatostatin-14 and somatostatin-28 pretreatment down-regulate somatostatin-14 receptors and have biphasic effects on forskolin-stimulated cyclic adenosine, 3',5'-monophosphate synthesis and adrenocorticotropin secretion in mouse anterior pituitary tumor cells. Heisler S, et al. **Endocrinology** 1985 Jul;117(1):217–25

Forskolin, an activator of adenylate cyclase, stimulates pancreatic insulin, glucagon, and somatostatin release in the dog: studies in vitro. Hermansen K. **Endocrinology** 1985 Jun;116(5):2251–8

Somatostatin secretion from the isolated perfused dog ileum. Hermansen K. **Endocrinology** 1985 Jul;117(1):287–91

Cysteamine induces a loss of tissue somatostatin-28 when measured as somatostatin-28(15–28)-like immunoreactivity but not when assessed as somatostatin-28(1–14)-like immunoreactivity: evidence for the importance of the disulfide bond for cysteamine action. Patel YC, et al. **Endocrinology** 1985 May;116(5):1699–702

Mouse hypothalamic somatostatin release: roles of calcium and calmodulin. Richardson S, et al. **Endocrinology** 1985 Jul; 117(1):369–75

Hepatic metabolism of somatostatin-14 and somatostatin-28: immunochemical characterization of the metabolic fragments and comparison of cleavage sites. Ruggere MD, et al. **Endocrinology** 1985 Jul;117(1):88–96

Antiserum to rat growth hormone (GH)-releasing factor suppresses but does not abolish antisomatostatin-induced GH release in the rat. Thomas CR, et al. **Endocrinology** 1985 Jun;116(6):2174–8

Immunoreactive and biologically active somatostatin in human and sheep milk. Werner H, et al. **Eur J Biochem** 1985 Apr 15;148(2):353–7

Pituitary growth hormone and hypothalamic somatostatin in young female rats versus old constant estrous female rats. Forman LJ, et al. **Experientia** 1985 May 15;41(5):653–4

Effect of long acting somatostatin-analogue, SMS 201 995, on gut hormone secretion in normal subjects. Kraenzlin ME, et al. **Experientia** 1985 Jun 15;41(6):738–40

Neurobiological actions of cysteamine. Brown M, et al. **Fed Proc** 1985 Jun;44(9):2556–60

Regulatory peptides (glucagon, somatostatin, substance P, and VIP) in the brain and gastrointestinal tract of Ambystoma mexicanum. Conlon JM, et al. **Gen Comp Endocrinol** 1985 Apr;58(1):150–8

Is somatostatin a humoral regulator of the endocrine pancreas and gastric acid secretion in man? Loud FB, et al. **Gut** 1985 May;26(5):445–9

Differential changes in calcitonin, somatostatin and gastrin/cholecystokinin-like immunoreactivities in rat thyroid parafollicular cells during ontogeny. Larsson LI. **Histochemistry** 1985; 82(2):121–30

Different effects of prostaglandin E1, E2 and D2 on pancreatic somatostatin release. Nishi S, et al. **Horm Metab Res** 1984 Dec; 16 Suppl 1:114–8

Effect of long and short photoperiod and/or pinealectomy on immunoreactive somatostatin in the Syrian hamster. Webb SM, et al. **Horm Metab Res** 1985 Feb;17(2):107–8

Z-DNA in the rat somatostatin gene. Hayes TE, et al. **J Biol Chem** 1985 Jul 5;260(13):8145–56

In situ hybridization of putative somatostatin mRNA within hypothalamus of the rat using synthetic oligonucleotide probes. Arentzen R, et al. **J Cell Biochem** 1985;27(4):415–22

A unique control mechanism in the regulation of insulin secretion. Secretagogue-induced somatostatin receptor recruitment. Draznin B, et al. **J Clin Invest** 1985 May;75(5):1510-6

Effects of cysteamine and antibody to somatostatin on islet cell function in vitro. Evidence that intracellular somatostatin deficiency augments insulin and glucagon secretion. Patel YC, et al. **J Clin Invest** 1985 Apr; 75(4):1249-55

Multiple forms of somatostatin-like immunoreactivity in the hypothalamus and amygdala of the rat: selective localization of somatostatin-28 in the median eminence. Pierotti AR, et al. **J Endocrinol** 1985 Jun; 105(3):383-9

Modulation of lymphocyte function by sensory neuropeptides. Payan DG, et al. **J Immunol** 1985 Aug;135(2 Suppl):783s-786s

Modulation by monoamines of somatostatin-sensitive adenylate cyclase on neuronal and glial cells from the mouse brain in primary cultures. Chneiweiss H, et al. **J Neurochem** 1985 Jun;44(6):1825-31

Localization of somatostatin receptors in secretion vesicles in anterior pituitary cells and pancreatic islets. Draznin B, et al. **J Recept Res** 1985; 5(1):83-103

Effect of a cyclic hexapeptide analog (L363,586) of somatostatin on the function of pancreas grafts in dogs. Liu T, et al. **J Surg Res** 1985 Jul; 39(1):39-45

Somatostatin: hormonal and therapeutic roles [editorial] **Lancet** 1985 Jul 13;2(8446):77-8

Different effects of three kinds of somatostatin (15-28, 1-14, 1-28) on rabbit's platelet aggregation. Fuse I, et al. **Life Sci** 1985 May 27; 36(21):2047-52

Somatostatin antagonist analogue stimulates growth in rats. Spencer GS, et al. **Life Sci** 1985 Jul 8;37(1):27-30

Effect of a selective octapeptide analogue of somatostatin on renal water excretion in the dog. Mountokalakis T, et al. **Metabolism** 1985 May; 34(5):408-9

Somatostatin release from the median eminence of unanesthetized rats: lack of correlation with pharmacologically suppressed growth hormone secretion. Fukata J, et al. **Neuroendocrinology** 1985 Mar; 40(3):193-200

The binding of somatostatin to rat synaptosomal membranes: effects of detergent solubilisation and of bacitracin. Weightman DR, et al. **Neuropeptides** 1985 Mar;6(1):83-92

Rat brain membranes possess two high-affinity binding sites for [3H]somatostatin. Weightman DR, et al. **Neurosci Lett** 1985 Apr 9; 55(2):161-6

Long-term suspension culture of isolated hypothalamic nuclei of the rat: morphological differentiation and release of substances influencing corticotropin and growth hormone secretion. Gyévai A, et al. **Neuroscience** 1985 Feb;14(2):519-33

The somatostatin systems of the guinea-pig brainstem. Taber-Pierce E, et al. **Neuroscience** 1985 May;15(1):215-35

Immunohistochemical studies of substance P, cholecystokinin-octapeptide and somatostatin in dorsal root ganglia of the rat. Tuchscherer MM, et al. **Neuroscience** 1985 Feb;14(2):593-605

Effects of MET-ENK, substance P and SRIF on the behavior of Hemichromis bimaculatus. Christ H. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):139-48

Somatostatin analogs: correlation of receptor affinity with inhibition of cyclic AMP formation in pancreatic acinar cells. Taparel D, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):109-14

Human pancreatic polypeptide and somatostatin in chronic renal failure. Lugari R, et al. **Proc Eur Dial Transplant Assoc Eur Ren Assoc** 1985; 21:614-7

Cerebrospinal fluid cholecystokinin, bombesin and somatostatin in schizophrenia and normals. Gerner RH, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(1):73-82

Effects of carbamazepine on cerebrospinal fluid somatostatin. Rubinow DR, et al. **Psychopharmacology (Berlin)** 1985;85(2):210-3

Evidence against prostaglandin-mediation of somatostatin-inhibition of gastric secretions. Albinus M, et al. **Regul Pept** 1985 Mar; 10(2-3):259-66

Somatostatin and GABA correlate with cervical autonomic nerve activity. Tonoue T, et al. **Regul Pept** 1985 Apr;10(4):299-307

Effects of somatostatin-14 and somatostatin-28 on plasma hormonal and gastric secretory responses to cephalic and gastrointestinal stimulation in man. Konturek SJ, et al. **Scand J Gastroenterol** 1985 Jan; 20(1):31-8

Effect of somatostatin on bethanechol-stimulated gastric pepsin secretion in gastric fistula dogs. Ladegaard L, et al. **Scand J Gastroenterol** 1985 Jan;20(1):87-91

Effects of substance P and somatostatin on taurocholate-stabilized and CCK- or secretin-induced choleresis in the anesthetized dog. Magnusson I, et al. **Scand J Gastroenterol** 1984 Nov;19(8):1007-14

The microvasculature of the small-intestinal mucosa of the rat: quantification of hemodynamic effects of topically applied cimetidine, ranitidine, somatostatin, and vasopressin. Neff M, et al. **Scand J Gastroenterol [Suppl]** 1985;112:6-11

High plasma levels of immunoreactive somatostatin in transgenic mice expressing a metallothionein-somatostatin fusion gene. Low MJ, et al. **Trans Assoc Am Physicians** 1984;97:205-9

[Somastostatin in domestic fowl] Baldissera FG, et al. **Riv Biol** 1985 Spring;78(1):123-8 (Eng. Abstr.) **(Ita)**

[Effect of somatostatin on the neurosecretory cells of the hypothalamic paraventricular nucleus and argentaffin cells of the antral part of the rat stomach] Kotel'nikova VI, et al. **Fiziol Zh SSSR** 1985 Feb; 71(2):206-12 (Eng. Abstr.) **(Rus)**

SOMATOTROPIN RELEASING HORMONE

Human pancreatic tumor GH-releasing factor. Thorner MO, et al. **Acta Neurochir (Wien)** 1985;75(1-4):72-80

Growth hormone releasing factor (GRF) and dopamine coexist in hypothalamic arcuate neurons. Meister B, et al. **Acta Physiol Scand** 1985 May;124(1):133-6

Physiological studies with somatocrinin, a growth hormone-releasing factor. Wehrenberg WB, et al. **Annu Rev Pharmacol Toxicol** 1985; 25:463-83 (98 ref.)

The effects of testosterone and estrogen on the pituitary growth hormone response to growth hormone-releasing factor. Wehrenberg WB, et al. **Biol Reprod** 1985 Mar;32(2):369-75

Plasma growth hormone secretion during constant growth hormone-releasing factor infusion. Takano K, et al. **Endocrinol Jpn** 1984 Dec;31(6):681-5

Pituitary response of growth hormone release in administration of hpGRF-44 to pregnant rats. Uchida N, et al. **Endocrinol Jpn** 1984 Dec; 31(6):831-5

Effects of intraventricular growth hormone-releasing factor on growth hormone release: further evidence for ultrashort loop feedback. Lumpkin MD, et al. **Endocrinology** 1985 May;116(5):2070-4

Dose-response characteristics of various peptides with growth hormone-releasing activity in the unanesthetized male rat. McCormick GF, et al. **Endocrinology** 1985 Jul;117(1):97-105

Antiserum to rat growth hormone (GH)-releasing factor suppresses but does not abolish antisomatostatin-induced GH release in the rat. Thomas CR, et al. **Endocrinology** 1985 Jun;116(6):2174-8

Interaction of growth hormone-releasing factor (GRF) and 14 GRF analogs with vasoactive intestinal peptide (VIP) receptors of rat pancreas. Discovery of (N-Ac-Tyr1,D-Phe2)-GRF(1-29)-NH2 as a VIP antagonist. Waelbroeck M, et al. **Endocrinology** 1985 Jun; 116(6):2643-9

Interaction between human pancreatic growth hormone releasing factor (hpGRF) and thyrotropin releasing hormone (TRH) on growth hormone secretion in domestic fowl. Harvey S, et al. **Horm Metab Res** 1985 Feb;17(2):113-4

Augmentation by propranolol of growth hormone-releasing hormone-(1-44)-NH2-induced growth hormone release in normal short and normal children. Chihara K, et al. **J Clin Endocrinol Metab** 1985 Aug;61(2):229-33

Growth hormone responses to continuous infusions of growth hormone-releasing hormone. Gelato MC, et al. **J Clin Endocrinol Metab** 1985 Aug;61(2):223-8

Effect of different growth hormone-releasing factors on the concentrations of growth hormone, insulin and metabolites in the plasma of sheep maintained in positive and negative energy balance. Hart IC, et al. **J Endocrinol** 1985 Apr;105(1):113-9

Effect of intravenous bovine growth hormone or human pancreatic growth hormone-releasing factor on milk production and plasma hormones and metabolites in sheep. Hart IC, et al. **J Endocrinol** 1985 May;105(2):189-96

GnRH pulse frequency determines LH pulse amplitude by altering the amount of releasable LH in the pituitary glands of ewes. Clarke IJ, et al. **J Reprod Fertil** 1985 Mar;73(2):425-31

Changes in pulsatile LH secretion and the positive and negative feedback actions of oestradiol after administration of a GnRH agonist in the ovariectomized ewe. Fitzgerald BP, et al. **J Reprod Fertil** 1985 Mar; 73(2):433-40

Radioimmunoassay for human growth hormone-releasing factor (hGRF 1-40): comparison of plasma immunoreactive GRF after intravenous and subcutaneous administration to rats. Rafferty B, et al. **Mol Cell Endocrinol** 1985 Jun;41(1):19-25

Expression of human growth hormone-releasing factor in transgenic mice results in increased somatic growth. Hammer RE, et al. **Nature** 1985 May 30-Jun 5;315(6018):413-6

Modification of basal and GRF-stimulated cyclic AMP levels and growth hormone release by phospholipid metabolic enzyme inhibitors. Cronin MJ, et al. **Neuroendocrinology** 1985 Apr;40(4):332-8

Long-term suspension culture of isolated hypothalamic nuclei of the rat: morphological differentiation and release of substances influencing corticotropin and growth hormone secretion. Gyévai A, et al. **Neuroscience** 1985 Feb;14(2):519-33

Growth hormone releasing hormone and growth hormone: genetic studies in familial growth hormone deficiency. Rogol AD, et al. **Pediatr Res** 1985 May;19(5):489-92

Levels of human and rat hypothalamic growth hormone-releasing factor as determined by specific radioimmunoassay systems. Audhya T, et al. **Proc Natl Acad Sci USA** 1985 May;82(9):2970-4

SPATIAL BEHAVIOR

Place preference conditioning with methylphenidate and nomifensine. Martin-Iverson MT, et al. **Brain Res** 1985 Apr 15;332(1):59-67

STARTLE REACTION

Central noradrenergic involvement in yohimbine excitation of acoustic startle: effects of DSP4 and 6-OHDA. Kehne JH, et al. **Brain Res** 1985 Mar 18;330(1):31-41

Antagonism of apomorphine-enhanced startle by alpha 1-adrenergic antagonists. Davis M, et al. **Eur J Pharmacol** 1985 Feb 5; 108(3):233-41

STEREOTYPED BEHAVIOR

Effect of duration of haloperidol treatment on DA receptor supersensitization in aging C57BL/6J mice. Randall PK, et al. **Brain Res** 1985 Apr 29;333(1):85-95

Sniffing, rearing and locomotor responses to the D-1 dopamine agonist R-SK&F 38393 and to apomorphine: differential interactions with the selective D-1 and D-2 antagonists SCH 23390 and metoclopramide. Molloy AG, et al. **Eur J Pharmacol** 1985 Feb 5;108(3):305-8

Opposite effects of sulpiride and metoclopramide on amphetamine-induced stereotypy. Robertson A, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):81-9

Unexpected potentiation by discriminant benzamide derivatives of stereotyped behaviours elicited by dopamine agonists in mice. Vasse M, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Apr; 329(2):108-16

Effect of gestational and neonatal styrene exposure on dopamine receptors. Zaidi NF, et al. **Neurobehav Toxicol Teratol** 1985 Jan-Feb;7(1):23-8

Effect of chronic haloperidol and quinacrine coadministration on striatal HVA levels and stereotypic behaviors in response to apomorphine in the rat. Deutsch SI, et al. **Neurochem Res** 1985 Apr;10(4):491-8

Antistereotypic effects of cholecystokinin octapeptide (CCK-8), ceruletide and related peptides on apomorphine-induced gnawing in sensitized mice. Zetler G. **Neuropharmacology** 1985 Mar;24(3):251-9

The morphogenesis of stereotyped behavior induced by the dopamine receptor agonist apomorphine in the laboratory rat. Szechtman H, et al. **Neuroscience** 1985 Mar;14(3):783-98

Serotonin and schizophrenia: correlations between serotonergic activity and schizophrenic motor behavior. King R, et al. **Psychiatry Res** 1985 Mar;14(3):235-40

Differential involvement of dopamine D-1 and D-2 receptors in the circling behaviour induced by apomorphine, SK & F 38393, pergolide and LY 171555 in 6-hydroxydopamine-lesioned rats. Arnt J, et al. **Psychopharmacology (Berlin)** 1985;85(3):346-52

Effects of apomorphine and haloperidol on 'spontaneous' stereotyped licking behaviour in the Cebus monkey. Korsgaard S, et al. **Psychopharmacology (Berlin)** 1985;85(2):240-3

A computer-supported method for analyzing behavioral observations: studies with stereotypy. Lewis MH, et al. **Psychopharmacology (Berlin)** 1985;85(2):204-9

Differential effects of dopamine D-1 and D-2 agonists and antagonists in 6-hydroxydopamine-lesioned rats. Arnt J. **Psychopharmacology [Suppl]** 1985;2:60-1

Intermittent treatment with droperidol, a short-acting neuroleptic, increases behavioral dopamine receptor sensitivity. Belmaker RH, et al. **Psychopharmacology [Suppl]** 1985;2:194-9

Induction and reversal of dopamine dyskinesia in rat, cat, and monkey. Lloyd KG, et al. **Psychopharmacology [Suppl]** 1985;2:200-10

[TRH and its analog (DN-1417). Effects on central dopaminergic system-dependent behaviors in rats and mice] Miyamoto M, et al. **Nippon Yakurigaku Zasshi** 1985 Mar;85(3):129-41 (Eng. Abstr.) **(Jpn)**

[Continuous suppression of methamphetamine-induced supersensitivity by chronic haloperidol administration] Kashihara K, et al. **Seishin Shinkeigaku Zasshi** 1984;86(11):928-32 **(Jpn)**

STRESS, PSYCHOLOGICAL

Interaction of chemical and psychogenic stress: biochemical response to repeated 'conditioned fear' and chronic carbon disulphide poisoning. Beneš V, et al. **Act Nerv Super (Praha)** 1985 Mar;27(1):23-5

Effects of psychological stress on male reproduction: a review. McGrady AV. **Arch Androl** 1984;13(1):1-7

Enhancement of some 5-HT-dependent behavioural responses following repeated immobilization in rats. Kennett GA, et al. **Brain Res** 1985 Mar 25;330(2):253-63

Platelet activation and secretion associated with emotional stress. Levine SP, et al. **Circulation** 1985 Jun;71(6):1129-34

Exercise and stress reduction. Rosch PJ. **Compr Ther** 1985 Apr; 11(4):10-5

Stress and immunomodulation: the role of depression and neuroendocrine function. Stein M, et al. **J Immunol** 1985 Aug; 135(2 Suppl):827s-833s

Reduction of the cyclic adenosine 3',5'-monophosphate response to catecholamines in rat brain slices after repeated restraint stress. Stone EA, et al. **J Pharmacol Exp Ther** 1985 May;233(2):382-8

Methionine-enkephalin inhibits stress-induced increases in noradrenaline turnover in brain regions of rats. Tanaka M, et al. **Jpn J Pharmacol** 1985 Jan;37(1):117-9

Psychic distress and the immune response. Tecoma ES, et al. **Life Sci** 1985 May 13;36(19):1799-812 (58 ref.)

Effects of emotional stress on the immune system. Miller NE. **Pavlov J Biol Sci** 1985 Apr-Jun;20(2):47-52

Brain amines and effects of chlordiazepoxide on motor activity in response to stress. Freeman GB, et al. **Pharmacol Biochem Behav** 1985 May; 22(5):665-70

Habituation to repeated stress is stressor specific. Kant GJ, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):631-4

A psychophysiological field study of stress at Three Mile Island. Gatchel RJ, et al. **Psychophysiology** 1985 Mar;22(2):175-81

[Spatial reorganization of the organelles of catecholamine-synthesizing group A1 neurons during emotional stress] Zhigadlo BA, et al. **Arkh Anat Gistol Embriol** 1985 Feb;88(2):11-6 (Eng. Abstr.) **(Rus)**

[The state of brain mitochondrial membranes in stress and its correction with drugs] Kresiun VI. **Biofizika** 1985 Mar-Apr;30(2):306-8 (Eng. Abstr.) **(Rus)**

[Changes in the substance P content of the blood and hypothalamus during experimental emotional stress] Iumatov EA, et al. **Biull Eksp Biol Med** 1985 Apr;99(4):397-9 (Eng. Abstr.) **(Rus)**

[Changes in the opioid peptide content of the adrenals of rats during immobilization stress] Val'dman AV, et al. **Biull Eksp Biol Med** 1985 Apr;99(4):404-6 (Eng. Abstr.) **(Rus)**

[Effect of phenazepam on the peripheral catecholaminergic systems in immobilization stress] Malikova LA, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):23-7 (Eng. Abstr.) **(Rus)**

[Changes in blood monoamine and 11-hydroxycorticosteroid levels in rats under the action of stress] Ugarova OP. **Fiziol Zh** 1985 Mar-Apr; 31(2):224-7 **(Rus)**

[The hemato-encephalic barrier in emotional stress] Belova TI, et al. **Usp Fiziol Nauk** 1985 Apr-Jun;16(2):61-76 (105 ref.) **(Rus)**

[Effect of an alimentary factor on the activity of the sympathetic-adrenal system in workers performing stressful work] Khotimchenko SA, et al. **Vopr Pitan** 1985 Mar-Apr;(2):36-9 **(Rus)**

SUBSTANCE P

Central action of substance P: possible role in reward. Stäubli U, et al. **Behav Neural Biol** 1985 Jan;43(1):100-8

The metabolism of neuropeptides. Endopeptidase-24.11 in human synaptic membrane preparations hydrolyses substance P. Matsas R, et al. **Biochem J** 1985 Jun 1;228(2):487-92

The role of substance P as a neurotransmitter in the reflexes of slow time courses in the neonatal rat spinal cord. Akagi H, et al. **Br J Pharmacol** 1985 Mar;84(3):663-73

The effect of a conditioning lesion on the regeneration rate of peripheral nerve axons containing substance P. Bisby MA, et al. **Brain Res** 1985 Jun 17;336(2):201-6

Substance P depolarizes nerve terminals in an autonomic ganglion. Dryer SE, et al. **Brain Res** 1985 Jun 10;336(1):190-4

Attenuation of the reflex pressor response to muscular contraction by a substance P antagonist. Kaufman MP, et al. **Brain Res** 1985 Apr 29; 333(1):182-4

Synaptic interaction between catecholaminergic neurons and substance P-immunoreactive axons in the caudal part of the nucleus of the solitary tract of the rat: demonstration by the electron microscopic mirror technique. Kubota Y, et al. **Brain Res** 1985 Apr 29;333(1):188-92

Coexistence of calcitonin gene-related peptide and substance P-like peptide in single cells of the trigeminal ganglion of the rat: immunohistochemical analysis. Lee Y, et al. **Brain Res** 1985 Mar 18; 330(1):194-6

Substance P mechanisms of the spinal cord related to vasomotor tone in the spontaneously hypertensive rat. Takano Y, et al. **Brain Res** 1985 May 13;334(1):105-16

Reduction of [3H]substance P binding in the intermediolateral cell column after sympathectomy. Takano Y, et al. **Brain Res** 1985 Apr 29; 333(1):193-6

Sciatic nerve transection produces death of dorsal root ganglion cells and reversible loss of substance P in spinal cord. Tessler A, et al. **Brain Res** 1985 Apr 22;332(2):209-18

The acute and chronic effects of capsaicin on slow excitatory transmission in rat dorsal horn. Urbán L, et al. **Brain Res** 1985 Mar 25; 330(2):390-6

Release of substance P from peripheral nerve terminals following electrical stimulation of the sciatic nerve. White DM, et al. **Brain Res** 1985 Jun 10;336(1):27-31

A comparison of the effects of serotonin, substance P and thyrotropin-releasing hormone on excitability of rat spinal motoneurons in vivo. White SR. **Brain Res** 1985 May 27;335(1):63-70

Ontogeny of substance P-containing fibers in the taste buds and the surrounding epithelium. I. Light microscopic analysis. Yamasaki H, et al. **Brain Res** 1985 Feb;350(1-2):301-5

A presynaptic site of action of substance P and vasoactive intestinal polypeptide on myenteric neurons. Yau WM, et al. **Brain Res** 1985 Mar 25;330(2):382-5

Vascular actions of VIP, substance P and neurotensin on the isolated perfused human fetal placenta. de Moura RS, et al. **Contrib Gynecol Obstet** 1985;13:174-5

Trials of serotonin, substance P and alpha 2-adrenergic receptor effects on the equine large colon. Sellers AF, et al. **Cornell Vet** 1985 Apr; 75(2):319-23

Sympathectomy enhances the substance P-mediated breakdown of the blood-aqueous barrier in response to infrared irradiation of the rabbit iris. Bynke G, et al. **Experientia** 1985 Apr 15;41(4):488-9

Substance P-like immunoreactivity in the frog dorsal root ganglia. Kemali M, et al. **Experientia** 1985 Apr 15;41(4):481-2

Regulatory peptides (glucagon, somatostatin, substance P, and VIP) in the brain and gastrointestinal tract of Ambystoma mexicanum. Conlon JM, et al. **Gen Comp Endocrinol** 1985 Apr;58(1):150-8

Vasoactive effects of substance P on isolated rabbit pulmonary artery. Tanaka DT, et al. **J Appl Physiol** 1985 Apr;58(4):1291-7

The role of substance P in arterial chemoreflex control of ventilation. Gallagher PJ, et al. **J Auton Nerv Syst** 1985 Feb-Mar; 12(2-3):195-210

Spinal cord substance P mediates bicuculline-induced activation of cardiovascular responses from the ventral medulla. Keeler JR, et al. **J Auton Nerv Syst** 1985 May;13(1):19-33

Origin of small primary afferent substance P-immunoreactive nerve fibers in the guinea-pig heart. Urban L, et al. **J Auton Nerv Syst** 1985 Apr; 12(4):321-31

Effect of substance P and other tachykinins on arterial pressure in guinea-pigs. Hancock JC, et al. **J Auton Pharmacol** 1985 Mar; 5(1):25-30

Modulation of lymphocyte function by sensory neuropeptides. Payan DG, et al. **J Immunol** 1985 Aug;135(2 Suppl):783s-786s

Substance P in human plasma is degraded by dipeptidyl peptidase IV, not by cholinesterase. Nausch I, et al. **J Neurochem** 1985 May; 44(5):1354-7

Autoradiographic localization and characterization of spinal cord substance P binding sites: high densities in sensory, autonomic, phrenic, and Onuf's motor nuclei. Charlton CG, et al. **J Neurosci** 1985 Jun; 5(6):1653-61

Cardiovascular effects of spinal cord substance P: studies with a stable receptor agonist. Keeler JR, et al. **J Pharmacol Exp Ther** 1985 Jun; 233(3):755-60

Blockade of slow excitatory post-synaptic potential by substance P antagonists in guinea-pig sympathetic ganglia. Konishi S, et al. **J Physiol (Lond)** 1985 Apr;361:115-30

Substance P raises neuronal membrane excitability by reducing inward rectification. Stanfield PR, et al. **Nature** 1985 Jun 6-12; 315(6019):498-501

Substance P enteric neurons mediate non-cholinergic transmission to the circular muscle of the guinea-pig intestine. Costa M, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):446-53

Substance P action on phosphoinositides in guinea-pig intestinal muscle: a possible transduction mechanism? Holzer P, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Mar;329(1):50-5

Substance P, enkephalins, somatostatin, cholecystokinin, oxytocin, and vasopressin in human spinal cord. Schoenen J, et al. **Neurology** 1985 Jun;35(6):881-90

Immunocytochemical localization of glutamic acid decarboxylase and substance P in the lateral cervical nucleus: a light and electron microscopic study in the cat. Blomqvist A, et al. **Neurosci Lett** 1985 May 14;56(2):229-33

Effects of substance P antagonists on the atropine-sensitive and atropine-resistant responses of guinea-pig ileum to substance P. Chahl LA. **Neurosci Lett** 1985 Mar 22;55(1):35-40

Binding sites for [3H]substance P on neurons of cultured rat spinal cord and brain stem: an autoradiographic study. Hösli E, et al. **Neurosci Lett** 1985 May 14;56(2):199-203

Opiate and histamine H1 receptors are present on some substance P-containing dorsal root ganglion cells. Ninkovic M, et al. **Neurosci Lett** 1985 Jan 7;53(1):133-7

Substance P concentrations in human cerebrospinal fluid vary inversely with age. Tam PK, et al. **Neurosci Lett** 1985 Mar 15;54(2-3):327-32

The comparative distribution of enkephalin, dynorphin and substance P in the human globus pallidus and basal forebrain. Haber SN, et al. **Neuroscience** 1985 Apr;14(4):1011-24

Effects of glutamate, substance P and eledoisin-related peptide on solitary tract neurones involved in respiration and respiratory reflexes. Henry JL, et al. **Neuroscience** 1985 Mar;14(3):863-73

Comparison of substance P and enkephalin distribution in rat brain: an overview using radioimmunocytochemistry. McLean S, et al. **Neuroscience** 1985 Mar;14(3):837-52

Immunohistochemical studies of substance P, cholecystokinin-octapeptide and somatostatin in dorsal root ganglia of the rat. Tuchscherer MM, et al. **Neuroscience** 1985 Feb;14(2):593-605

Effects of MET-ENK, substance P and SRIF on the behavior of Hemichromis bimaculatus. Christ H. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):139-48

Cardiovascular interactions between methionine-enkephalin and substance P in the conscious dog. Sander GE, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):133-7

Sympathetic neuron density differentially regulates transmitter phenotypic expression in culture. Adler JE, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(12):4296-300

Identification of substance P precursor forms in human brain tissue. Nyberg F, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(11):3921-4

The effects of vagal nerve stimulation on endoluminal release of serotonin and substance P into the feline small intestine. Grønstad KO, et al. **Scand J Gastroenterol** 1985 Mar;20(2):163-9

Effects of substance P and somatostatin on taurocholate-stabilized and CCK- or secretin-induced choleresis in the anesthetized dog. Magnusson I, et al. **Scand J Gastroenterol** 1984 Nov;19(8):1007-14

Immunohistochemical demonstration of nociceptors in the ligamentous structures of the lumbar spine. Korkala O, et al. **Spine** 1985 Mar; 10(2):156-7

[Recent advances in research on substance P and related neuropeptides] Kanazawa I. **No To Hattatsu** 1985 Mar;17(2):94-102 (17 ref.) **(Jpn)**

[Changes in the substance P content of the blood and hypothalamus during experimental emotional stress] Iumatov EA, et al. **Biull Eksp Biol Med** 1985 Apr;99(4):397-9 (Eng. Abstr.) **(Rus)**

SUBSTANCE USE DISORDERS

[Attempted suicide with barbiturate after glue sniffing] Sami HO, et al. **Orv Hetil** 1985 Mar 31;126(13):781-3 (Eng. Abstr.) **(Hun)**

SUCKING BEHAVIOR

Plasma prolactin in the rat during suckling without prior separation from pups. Mattheij JA, et al. **Acta Endocrinol (Copenh)** 1985 Apr; 108(4):468-74

Control of suckling and feeding by methysergide in weaning albino rats: a determination of Y-maze preferences. Stoloff ML, et al. **Dev Psychobiol** 1985 May;18(3):273-85

SYMPATHOMIMETICS

In vitro studies on the pharmacological properties of diacetolol, the major metabolite of acebutolol in man. Borchard U, et al. **Arch Int Pharmacodyn Ther** 1985 Jan;273(1):4-17

Adrenergic ligand binding in human serum. Sager G, et al. **Biochem Pharmacol** 1985 Aug 1;34(15):2812-5

Comparison of postnatal changes in alpha 1-adrenoceptor binding and adrenergic stimulation of phosphoinositide hydrolysis in rat cerebral cortex. Schoepp DD, et al. **Biochem Pharmacol** 1985 Aug 1; 34(15):2705-11

The effect of glucagon and adrenergic agonists on intracellular pH of isolated rat hepatocytes. Deutsch CJ, et al. **J Biol Chem** 1985 Jun 10; 260(11):6808-10

Effects of beta-adrenoceptor antagonist administration on beta 2-adrenoceptor density in human lymphocytes. The role of the 'intrinsic sympathomimetic activity'. Brodde OE, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Feb;328(4):417-22

[Heptaminol adenosine phosphate and the premenstrual syndrome] Anglade JP. **Rev Fr Gynecol Obstet** 1985 Mar;80(4):245-7 (Eng. Abstr.) **(Fre)**

SYNAPTIC RECEPTORS

Effects of long-term drug treatments on the sensitivity of presynaptic receptors regulating neurotransmitter release. Raiteri M, et al. **Ann Ist Super Sanita** 1984;20(1):57-64

Corticosterone modulation of neurotransmitter receptors in rat hippocampus: a quantitative autoradiographic study. Biegon A, et al. **Brain Res** 1985 Apr 22;332(2):309-14

The ontogenetic development of neurotensin-like immunoreactivity and neurotensin receptors in the cat striatum. Goedert M, et al. **Brain Res** 1985 May;352(1):127-31

Age-related changes in 5HT uptake and [3H]imipramine binding sites in rat cerebral cortex. Brunello N, et al. **Eur J Pharmacol** 1985 Apr 16;110(3):393-4

Possible relationship between antimanic effect and activity of zotepine to 5HT1 receptor. Harada T, et al. **Folia Psychiatr Neurol Jpn** 1984; 38(4):473-80

Ibotenic acid analogues. Synthesis, molecular flexibility, and in vitro activity of agonists and antagonists at central glutamic acid receptors. Lauridsen J, et al. **J Med Chem** 1985 May;28(5):668-72

High- and low-affinity binding components for [3H]imipramine in rat cerebral cortex. Conway PG, et al. **J Neurochem** 1985 Jul; 45(1):206-9

5-Methoxytryptoline, a competitive endocoid acting at [3H]imipramine recognition sites in human platelets. Segonzac A, et al. **J Neurochem** 1985 Jul;45(1):249-56

Pharmacological characterization of postsynaptic receptors for excitatory amino acids in Purkinje cell dendrites in the guinea pig cerebellum. Kimura H, et al. **J Pharmacobiodyn** 1985 Feb;8(2):119-27

Cardiovascular effects of spinal cord substance P: studies with a stable receptor agonist. Keeler JR, et al. **J Pharmacol Exp Ther** 1985 Jun; 233(3):755-60

Effects of calcium hopantenate on neurotransmitter receptors in the rat brain. Ogawa N, et al. **Jpn J Pharmacol** 1985 Jan;37(1):45-50

Modulation of receptor sensitivity and action potentials by transmitters in vertebrate neurones. Koketsu K. **Jpn J Physiol** 1984;34(6):945-60 (59 ref.)

3H-Imipramine binding sites in platelets of hospitalized psychiatric patients. Gentsch C, et al. **Psychiatry Res** 1985 Mar;14(3):177-87

[Antenatal effect of imipramine on the ontogeny of the imipramine receptors in the cerebral cortex of rats] Pirogova MV, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):35-8 (Eng. Abstr.) **(Rus)**

TERRITORIALITY

Short-term changes in plasma levels of hormones during establishment and defense of a breeding territory in male song sparrows, Melospiza melodia. Wingfield JC. **Horm Behav** 1985 Jun;19(2):174-87

TESTOSTERONE

Neuro-endocrine effects of isotheoline. Zhelyazkov D, et al. **Acta Physiol Pharmacol Bulg** 1984;10(4):53-8

Long-term, pulsatile, low dose, subcutaneous luteinizing hormone-releasing hormone administration in men with idiopathic oligozoospermia. Failure of therapeutic and hormonal response. Fauser BC, et al. **Andrologia** 1985 Mar-Apr;17(2):143-9

Regulation of infant and developing rat testicular gonadotropin and prolactin receptors and steroidogenesis by treatments with human chorionic gonadotropin, gonadotropin-releasing hormone analogs, bromocriptine, prolactin, and estrogen. Huhtaniemi IT, et al. **Biol Reprod** 1985 May;32(4):721-32

The effects of testosterone and estrogen on the pituitary growth hormone response to growth hormone-releasing factor. Wehrenberg WB, et al. **Biol Reprod** 1985 Mar;32(2):369-75

Effects of steroid hormones on the neuropil of the hypothalamic paraventricular nucleus of male chickens. Panzica GC, et al. **Cell Tissue Res** 1985;240(1):169-74

The influence of testosterone in the brain of the male rat on levels of serotonin (5-HT) and hydroxyindole-acetic acid (5-HIAA). Martinez-Conde E, et al. **Comp Biochem Physiol [C]** 1985; 80(2):411-4

The role of calcium/phospholipid-dependent protein kinase in Leydig cell steroidogenesis. Lin T. **Endocrinology** 1985 Jul;117(1):119-26

Increased hepatic and reduced prostatic prolactin (PRL) binding in iron deficiency and during neuroleptic treatment: correlation with changes in serum PRL and testosterone. Barkey RJ, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):193-200

FSH and LH response to testosterone and gonadotropin-releasing hormone in aging male rats. Sartin JL, et al. **Exp Aging Res** 1984 Winter; 10(4):183-7

Seasonal variations in plasma luteinizing hormone and testosterone levels in the European badger Meles meles L. Audy MC, et al. **Gen Comp Endocrinol** 1985 Mar;57(3):445-53

Seasonal changes in plasma testosterone, thyroxine, and cortisol levels in wild rabbits (Oryctolagus cuniculus algirus) of Zembra island. Ben Saad M, et al. **Gen Comp Endocrinol** 1985 Mar;57(3):383-8

Annual and diurnal cycles in plasma testosterone and thyroxine in the male green sea turtle Chelonia mydas. Licht P, et al. **Gen Comp Endocrinol** 1985 Mar;57(3):335-44

Effect of temperature and darkness on testosterone concentration in the testes of intact frogs (Rana esculenta) treated with gonadotrophin-releasing hormone analog (HOE 766). Pierantoni R, et al. **Gen Comp Endocrinol** 1985 Apr;58(1):128-30

Short-term changes in plasma levels of hormones during establishment and defense of a breeding territory in male song sparrows, Melospiza melodia. Wingfield JC. **Horm Behav** 1985 Jun;19(2):174-87

Hyperprolactinaemia and testosterone production. Observations in 2 men on long-term dialysis. Stegmayr B, et al. **Horm Res** 1985; 21(4):224-8

Possible role of prolactin in the inhibitory effect of testosterone on the hypothalamic-pituitary-testicular axis in the rat. Tresguerres JA, et al. **J Endocrinol** 1985 Jun;105(3):423-7

Newborn and immature rat testes contain gonadotropin-releasing hormone (GnRH) receptors, and their testosterone production is stimulated by a GnRH agonist in vitro. Huhtaniemi IT, et al. **Mol Cell Endocrinol** 1985 Apr;40(1):41-4

Influence of perinatal androgen on the sexually dimorphic distribution of tyrosine hydroxylase-immunoreactive cells and fibers in the anteroventral periventricular nucleus of the rat. Simerly RB, et al. **Neuroendocrinology** 1985 Jun;40(6):501-10

Suppression of male copulatory behavior by delta 9-THC is not dependent on changes in plasma testosterone or hypothalamic dopamine or serotonin content. Shrenker P, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):415-20

Neonatal phenobarbital imprinting of hepatic microsomal enzymes in adult rats: modulation by neonatal testosterone presence. Bagley DM, et al. **Toxicol Appl Pharmacol** 1985 Jun 30;79(2):227-35

THIORIDAZINE

Effects of thioridazine and fluphenazine on the pituitary, thyroid and adrenal functions in patients with paranoid schizophrenia. Horodnicki JM, et al. **Psychiatr Pol** 1984 May-Jun;18(3):205-11

Lateral ventricular enlargement and clinical response in schizophrenia. Smith RC, et al. **Psychiatry Res** 1985 Mar;14(3):241-53

A computer-supported method for analyzing behavioral observations: studies with stereotypy. Lewis MH, et al. **Psychopharmacology (Berlin)** 1985;85(2):204-9

THIOTHIXENE

Acute thiothixene overdose. Kemal M, et al. **J Anal Toxicol** 1985 Mar-Apr;9(2):94-5

Treatment-resistant catatonic stupor and combined lithium-neuroleptic therapy: a case report. Climo LH. **J Clin Psychopharmacol** 1985 Jun; 5(3):166-70

THYROID HORMONES

Thyroid hormones reversibly suppress somatostatin secretion and immunoreactivity in cultured neocortical cells. Peterfreund RA, et al. **Brain Res** 1985 Mar 4;328(2):259-70

Modulatory effect of thyroid hormones on uptake of phosphate and other solutes across luminal brush border membrane of kidney cortex. Yusufi AN, et al. **Endocrinology** 1985 Jun;116(6):2438-49

3,5,3'-Triiodothyronine receptors and thyroxine 5'-monodeiodinating activity in thyroid hormone-insensitive amphibia. Galton VA. **Gen Comp Endocrinol** 1985 Mar;57(3):465-71

Relationship of the menstrual cycle and thyroid hormones to whole-body protein turnover in women. Garrel DR, et al. **Hum Nutr Clin Nutr** 1985 Jan;39(1):29-37

Changes in cardiac function following administration of thyroid hormones in thyroidectomised rats: assessment using the isolated working rat heart preparation. Brooks I, et al. **J Cardiovasc Pharmacol** 1985 Mar-Apr; 7(2):290-6

Routine measurement of thyroid hormones and FSH in infertility not worthwhile [letter] Conway DI, et al. **Lancet** 1985 Apr 27; 1(8435):977-8

Correlation between thyroid function and nephron loss. Giordano C, et al. **Life Support Syst** 1985 Jan-Mar;3(1):41-3

Thyroid gland volume and serum concentrations of thyroid hormones in chronic renal failure. Hegedüs L, et al. **Nephron** 1985;40(2):171-4

[Effect of preventive administration of lithium carbonate on serum concentrations of various pituitary and peripheral hormones in patients with endogenous depression] Horodnicki JM, et al. **Psychiatr Pol** 1984 Jul-Aug;18(4):319-25 (Eng. Abstr.) **(Pol)**

[Hormones of the thyroid gland and pancreas in lethally irradiated rats] Ahlersová E, et al. **Bratisl Lek Listy** 1985 Apr;83(4):433-9 (Eng. Abstr.) **(Slo)**

[The thyroid and amiodarone (I). Changes in peripheral thyroid hormones caused by prolonged treatment with amiodarone] Gómez JM, et al. **Med Clin (Barc)** 1985 Mar 16;84(10):381-3 (Eng. Abstr.) **(Spa)**

THYROTROPIN

Serum concentrations of thyroxine, 3,5,3'-triiodothyronine, thyrotropin, and prolactin in dogs before and after thyrotropin-releasing hormone administration. Kaufman J, et al. **Am J Vet Res** 1985 Feb; 46(2):486-92

Sensitive immunoradiometric assay (IRMA) for serum thyrotropin may be insufficient to make the thyrotropin-releasing-factor test unnecessary [letter] Rodriquez-Espinosa J, et al. **Clin Chem** 1985 Jun; 31(6):1081-2

Intranasal thyrotrophin releasing hormone is a potent stimulus for TSH release in man (comparison with intravenous and oral TRH). Staub JJ, et al. **Clin Endocrinol (Oxf)** 1985 Apr;22(4):567-72

Functional specificity of gonadotropin and thyrotropin in Fundulus heteroclitus. Brown CL, et al. **Gen Comp Endocrinol** 1985 May; 58(2):252-8

Administration of low doses of TSH result in a rapid increase in the metabolic rate of young lambs. Lynch MA, et al. **Horm Metab Res** 1985 Mar;17(3):136-40

Thyroxine binding and TSH in recurrent depressive episodes. Tollefson G, et al. **J Clin Psychiatry** 1985 Jul;46(7):267-72

Hypothalamo-pituitary regulation of thyrotrophin secretion in chronically catheterized Brattleboro rats. Wolf BA, et al. **J Endocrinol** 1985 May; 105(2):277-83

Photoperiodic regulation of thyroid responsiveness to TSH in Fundulus heteroclitus. Grau EG, et al. **J Exp Zool** 1985 May;234(2):199-205

Effects of TSH on iodination in rat thyroid follicles studied by autoradiography. Ofverholm T, et al. **Mol Cell Endocrinol** 1985 Apr; 40(1):1-7

Acute effect of triiodothyronine on the dynamics of thyrotropin release from superfused anterior pituitary cells. Shiota K, et al. **Mol Cell Endocrinol** 1985 Jun;41(1):79-84

Oxytocin attenuates TRH-induced TSH release from rat pituitary cells. Frawley LS, et al. **Neuroendocrinology** 1985 Mar;40(3):201-4

Role of the sympathetic nervous system in the control of thyroid compensatory growth of normal and hypophysectomized rats. Romeo HE, et al. **Neuroendocrinology** 1985 Apr;40(4):309-15

THYROXINE

Plasma growth hormone and thyroxine levels in the chronically catheterised pig foetus and the effect of thyrotrophin releasing hormone. Macdonald AA, et al. **Acta Endocrinol (Copenh)** 1985 May; 109(1):126-9

Effect of thyroxine on hepatic glucose-6-phosphatase activity and glycogen content of toad (Bufo melanostictus) and Lata fish (Ophicephalus punctatus) at different stages of life. Paul AK, et al. **Acta Physiol Hung** 1985;65(3):233-8

Effect of propylthiouracil dose on serum thyroxine, growth, and weaning in young rats. Blake HH, et al. **Am J Physiol** 1985 May; 248(5 Pt 2):R524-30

Transport of thyroxine bound to human prealbumin into rat liver. Pardridge WM, et al. **Am J Physiol** 1985 May;248(5 Pt 1):G545-50

Serum concentrations of thyroxine, 3,5,3'-triiodothyronine, thyrotropin, and prolactin in dogs before and after thyrotropin-releasing hormone administration. Kaufman J, et al. **Am J Vet Res** 1985 Feb; 46(2):486-92

Effects of D- and L-thyroxine on the glucocorticoid binding capacity of adult rat liver. Naito K, et al. **Biochem Biophys Res Commun** 1985 Jun 14;129(2):447-52

Regulation of NAD- and NADP-linked isocitrate dehydrogenase by thyroxine in the brain and liver of female rats of various ages. Yadav RN. **Biochem Med** 1985 Jun;33(3):312-9

In vitro synthesis of thyroxine in a low molecular weight polypeptide fragment from human thyroglobulin. Lejeune PJ, et al. **Biochimie** 1985 Feb;67(2):199-203

Least squares calculation of the standard curve for the EMIT manual thyroxin assay [letter] Johnson D Jr, et al. **Clin Chem** 1985 Jul; 31(7):1247

Differences between measurements of free thyroxin in serum from siliconized and nonsiliconized tubes are influenced by analyte concentration [letter] Ordóñez-Llanos J, et al. **Clin Chem** 1985 Jul; 31(7):1249-50

The production and characterisation of a monoclonal antibody to thyroxine. Mpoko CN, et al. **Clin Chim Acta** 1985 Mar 15; 146(2-3):215-22

The effect of in vivo glucose administration on human erythrocyte Ca2+-ATPase activity and on enzyme responsiveness in vitro to thyroid hormone and calmodulin. Davis FB, et al. **Diabetes** 1985 Jul; 34(7):639-46

Seasonal changes in plasma testosterone, thyroxine, and cortisol levels in wild rabbits (Oryctolagus cuniculus algirus) of Zembra island. Ben Saad M, et al. **Gen Comp Endocrinol** 1985 Mar;57(3):383-8

3,5,3'-Triiodothyronine receptors and thyroxine 5'-monodeiodinating activity in thyroid hormone-insensitive amphibia. Galton VA. **Gen Comp Endocrinol** 1985 Mar;57(3):465-71

Thyroid hormone binding in serum of 15 vertebrate species: isolation of thyroxine-binding globulin and prealbumin analogs. Larsson M, et al. **Gen Comp Endocrinol** 1985 Jun;58(3):360-75

Annual and diurnal cycles in plasma testosterone and thyroxine in the male green sea turtle Chelonia mydas. Licht P, et al. **Gen Comp Endocrinol** 1985 Mar;57(3):335-44

Thyroxine binding and TSH in recurrent depressive episodes. Tollefson G, et al. **J Clin Psychiatry** 1985 Jul;46(7):267-72

Immunocytochemistry of luteinizing hormone-releasing hormone during spontaneous and thyroxine-induced metamorphosis of bullfrogs. Whalen R, et al. **J Exp Zool** 1985 Apr;234(1):131-44

Effect of breast-feeding vs formula-feeding on circulating thyroxine levels in premature infants. Oberkotter LV, et al. **J Pediatr** 1985 May; 106(5):822-5

Chronic thyroxine treatment of rats down-regulates the noradrenergic cyclic AMP generating system in cerebral cortex. Schmidt BH, et al. **J Pharmacol Exp Ther** 1985 May;233(2):466-72

Lead poisoning and euthyroid hyperthyroxinaemia [letter] Tiwari I, et al. **Lancet** 1985 Jun 29;1(8444):1508-9

Photoperiodic and light spectral conditions which inhibit circulating concentrations of thyroxine in the male hamster. Vaughan MK, et al. **Life Sci** 1985 Jun 10;36(23):2183-8

The effects of acute and chronic treatment with triiodothyronine and thyroxine on the hypothalamic and telencephalic catecholamine nerve terminal systems of the hypophysectomized male rat. Chronic treatment modulates catecholamine utilization in discrete catecholamine nerve terminal systems. Andersson K, et al. **Neuroendocrinology** 1985 May; 40(5):398-408

Role of thyroxine in the postnatal development of rat hepatic tryptophan oxygenase and ornithine aminotransferase. Vandewater LJ, et al. **Proc Soc Exp Biol Med** 1985 May;179(1):83-9

[Automated recording of precision profiles for the radioimmunological determination of T4 using a pocket calculator of the HP-41 CV type] Ditu M, et al. **Ann Endocrinol (Paris)** 1984;45(6):393-6 (Eng. Abstr.) **(Fre)**

[Lugol's solution and thyroid gland activity in cattle. Determination of the total thyroxine in blood plasma as a method for evaluating thyroid gland activity] Braun U, et al. **Tierarztl Prax** 1985;Suppl 1:33-40 (Eng. Abstr.) **(Ger)**

[Evaluation of free thyroxine radioimmunoassays for assessing thyroid function in hypoproteinemia] Matsumura K, et al. **Kaku Igaku** 1985 Apr;22(4):511-20 (Eng. Abstr.) **(Jpn)**

[Effect of the administration of thyroxine and estradiol on the morphology of the anterior lobe of the pituitary gland] Szczurek Z, et al. **Patol Pol** 1984 Oct-Dec;35(4):499-507 (Eng. Abstr.) **(Pol)**

TIME PERCEPTION

Arginine vasopressin inoculates against age-related changes in temporal memory. Meck WH, et al. **Ann NY Acad Sci** 1985;444:453-6

Cannabis, atropine, and temporal information processing. Hicks RE, et al. **Neuropsychobiology** 1984;12(4):229-37

TRANQUILIZING AGENTS

1st Czechoslovak Conference on Biological Psychiatry. Karlovy Vary (Karlsbad), September 1983. Abstracts. **Act Nerv Super (Praha)** 1985 Mar;27(1):60-72

Sex differences in the use of alcohol and tranquilizers: testing a role convergence hypothesis. Bell R, et al. **Am J Drug Alcohol Abuse** 1984; 10(4):551-61

Chlordiazepoxide toxicity in Limbitrol overdose [letter] Goethe JW, et al. **Am J Psychiatry** 1985 Jun;142(6):774

Some neurochemical effects of a new antianxiety agent centazolone. Laxmi CV, et al. **Indian J Exp Biol** 1984 Dec;22(12):649-52

Determination of cyclobenzaprine in plasma and urine using capillary gas chromatography with nitrogen-selective detection. Constanzer ML, et al. **J Chromatogr** 1985 May 3;339(2):414-8

Serotonin antagonist pirenperone inhibits sexual behavior in the male rat: attenuation by quipazine. Mendelson SD, et al. **Pharmacol Biochem Behav** 1985 Apr;22(4):565-71

[Practical advice concerning the immobilization of wild and zoo animals] Wiesner H, et al. **Tierarztl Prax** 1985;13(1):113-27 (Eng. Abstr.) **(Ger)**

TRANQUILIZING AGENTS, MAJOR

Clinical characteristics of hospitalized psychotic patients who refuse antipsychotic drug therapy. Zito JM, et al. **Am J Psychiatry** 1985 Jul; 142(7):822-6

Prolonged pharmacologic activity of neuroleptics [letter] Campbell A, et al. **Arch Gen Psychiatry** 1985 Jun;42(6):637

Selection of neuroleptic dosage [letter] Teicher MH, et al. **Arch Gen Psychiatry** 1985 Jun;42(6):636-7

Schizophrenia with good and poor outcome. I: Early clinical features, response to neuroleptics and signs of organic dysfunction. Kolakowska T, et al. **Br J Psychiatry** 1985 Mar;146:229-39

Platelet monoamine-oxidase activity in schizophrenia. Relation to genetic load of the illness and treatment with antipsychotic drugs. Kemali D, et al. **Encephale** 1985 Jan-Feb;11(1):31-4

Increased hepatic and reduced prostatic prolactin (PRL) binding in iron deficiency and during neuroleptic treatment: correlation with changes in serum PRL and testosterone. Barkey RJ, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):193-200

Selective D-1 dopamine receptor increase following chronic treatment with SCH 23390. Creese I, et al. **Eur J Pharmacol** 1985 Feb 12; 109(1):127-8

Sedation and sleep induced by high doses of apomorphine after blockade of D-1 receptors by SCH 23390. Gessa GL, et al. **Eur J Pharmacol** 1985 Feb 26;109(2):269-74

Repeated treatment with imipramine decreased the number of [3H]piflutixol binding sites in the rat striatum. Klimek V, et al. **Eur J Pharmacol** 1985 Feb 12;109(1):131-2

Possible relationship between antimanic effect and activity of zotepine to 5HT1 receptor. Harada T, et al. **Folia Psychiatr Neurol Jpn** 1984; 38(4):473-80

Pharmacokinetics and initial distribution of a new neuroleptic agent picobenzide (M-14012-4). Calvo MV, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 May;23(5):233-7

Stimulants and neuroleptics in hyperactive children [letter] Gualtieri CT, et al. **J Am Acad Child Psychiatry** 1985 May;24(3):363-4

Neuroleptic bioequivalency: tablet versus concentrate. Fann WE, et al. **J Clin Pharmacol** 1985 May-Jun;25(4):305-6

Drugs and the quality of life: the patient's point of view. Diamond R.

J Clin Psychiatry 1985 May;46(5 Pt 2):29-35

Compliance issues in outpatient treatment. Kane JM. **J Clin Psychopharmacol** 1985 Jun;5(3 Suppl):22S-27S

Focal neuroleptization: an approach to optimal dosing for initial and continuing therapy. Tupin JP. **J Clin Psychopharmacol** 1985 Jun; 5(3 Suppl):15S-21S

Synthesis and neuroleptic activity of 3-(1-substituted-4-piperidinyl)-1,2-benzisoxazoles. Strupczewski JT, et al. **J Med Chem** 1985 Jun;28(6):761-9

Problems in classification of schizophrenics as neuroleptic responders and nonresponders. Csernansky JG, et al. **J Nerv Ment Dis** 1985 Jun; 173(6):325-31 (93 ref.)

Inactivation of D1 and D2 dopamine receptors by N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline in vivo: selective protection by neuroleptics. Meller E, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):656-62

Mental health dilemmas. Parts of a whole. Lacey R. **Nurs Times** 1985 May 1-7;81(18):27-8

Effects of neuroleptics on rate and duration of operant versus reflexive licking in rats. Gramling SE, et al. **Pharmacol Biochem Behav** 1985 Apr; 22(4):541-5

One-year outcome of schizophrenic patients--the interaction of chronicity and neuroleptic treatment. Gaebel W, et al. **Pharmacopsychiatry** 1985 May;18(3):235-9

1.2-Anellated 1.4-benzodiazepine derivatives--a new class of antipsychotics. Ruhland M, et al. **Pharmacopsychiatry** 1985 Jan; 18(1):174-7

Amphetamine response and relapse risk after depot neuroleptic discontinuation. Angrist B, et al. **Psychopharmacology (Berlin)** 1985; 85(3):277-83

Chronic neuroleptic treatment and mesolimbic dopamine denervation induce behavioural supersensitivity to opiates. Stinus L, et al. **Psychopharmacology (Berlin)** 1985;85(3):323-8

Pharmacological differentiation of dopamine D-1 and D-2 antagonists after single and repeated administration. Christensen AV, et al. **Psychopharmacology [Suppl]** 1985;2:182-90

Receptor-binding profiles of neuroleptics. Hyttel J, et al. **Psychopharmacology [Suppl]** 1985;2:9-18

Akinesia, tardive dysmentia, and frontal lobe disorder in schizophrenia. Goldberg E. **Schizophr Bull** 1985;11(2):255-63

Tardive dysmentia : further comments. Jones BD. **Schizophr Bull** 1985; 11(2):187-9

Acutely psychotic patients: a treatment approach. Wagemaker H, et al. **South Med J** 1985 Jul;78(7):833-7

[Benzonitrile and structural analogs. Action of para-aminobenzonitrile on the central nervous system] Cheav SL, et al. **Ann Pharm Fr** 1984; 42(4):367-78 (Eng. Abstr.) **(Fre)**

[Adsorption of cationic amphiphilic drugs to antacids and adsorbents. 3. Adsorption of tricyclic antidepressive agents and neuroleptics in relation to their colloid chemical properties] Thomas K, et al. **Pharm Acta Helv** 1985;60(2):39-47 (Eng. Abstr.) **(Ger)**

[The effect of psychopharmacologic agents on the passive transport of Ca2+ induced by vanadate in human erythrocytes] Pogády J, et al. **Bratisl Lek Listy** 1985 Apr;83(4):345-52 (Eng. Abstr.) **(Slo)**

TRANQUILIZING AGENTS, MINOR

The relationship between buspirone bioavailability and dose in healthy subjects. Gammans RE, et al. **Biopharm Drug Dispos** 1985 Apr-Jun; 6(2):139-45

Rapid gas chromatographic assay for monitoring valnoctamide in plasma. Bialer M, et al. **J Chromatogr** 1985 Feb 8;337(2):408-11

1-Azacycloalkyl-1,4-benzodiazepin-2-ones with antianxiety-antidepressant actions. Sugasawa T, et al. **J Med Chem** 1985 Jun;28(6):699-707

Effects of acute and chronic treatment on the pro- and anti-convulsant actions of CL 218, 872, PK 8165 and PK 9084, putative ligands for the benzodiazepine receptor. File SE, et al. **J Pharm Pharmacol** 1985 Apr;37(4):252-6

Animal models for the study of anti-anxiety agents: a review. Treit D. **Neurosci Biobehav Rev** 1985 Summer;9(2):203-22

Evidence that tolerance develops to the anxiolytic effect of diazepam in rats. Treit D. **Pharmacol Biochem Behav** 1985 Mar;22(3):383-7

The sedative effects of CL 218,872, like those of chlordiazepoxide, are reversed by benzodiazepine antagonists. File SE, et al. **Psychopharmacology (Berlin)** 1985;85(3):295-300

A comparison between chlordiazepoxide and CL 218,872--a synthetic nonbenzodiazepine ligand for benzodiazepine receptors on spontaneous locomotor activity in rats. McElroy JF, et al. **Psychopharmacology (Berlin)** 1985;85(2):224-6

The effects of compounds related to gamma-aminobutyrate and benzodiazepine receptors on behavioural responses to anxiogenic stimuli in the rat: punished barpressing. Quintero S, et al. **Psychopharmacology (Berlin)** 1985;85(2):244-51

Anxiolytic drugs and the acquisition of conditioned fear in mice. Sanger DJ, et al. **Psychopharmacology (Berlin)** 1985;85(3):284-8

[Thiophene as a structural element in physiologically active substances. 15. Thiophene analogs of an anxiolytic acting 1,2,4-triazolo[4,3-b]pyridazine] Binder D, et al. **Arch Pharm (Weinheim)** 1985 Mar;318(3):243-9 (Eng. Abstr.) **(Ger)**

[Anxiolytic action of sodium valproate (possible role of gamma-aminobutyric acid in affective disorders)] Raevskii KS, et al. **Zh Nevropatol Psikhiatr** 1985;85(4):574-9 (Eng. Abstr.) **(Rus)**

TRANYLCYPROMINE

Lack of pharmacokinetic interaction of carbamazepine with tranylcypromine [letter] Joffe RT, et al. **Arch Gen Psychiatry** 1985 Jul; 42(7):738

Platelet monoamine oxidase inhibition by deprenyl and tranylcypromine: implications for clinical use. Simpson GM, et al. **Biol Psychiatry** 1985 Jun;20(6):684-7

TRIFLUOPERAZINE

Sites of interaction of calmodulin with trifluoperazine and glucagon. Steiner RF, et al. **Arch Biochem Biophys** 1985 Jul;240(1):297-311

Behavioral interaction of adenosine and trifluoperazine in mice. DeLong RE, et al. **Neurosci Lett** 1985 Jan 7;53(1):101-7

Evidence that a Ca2+ chelator and a calmodulin blocker interfere with the structure of inter-Sertoli junctions. Franchi E, et al. **Tissue Cell** 1985;17(1):13-25

The effect of trifluoperazine (Stellazine) on Hymenolepis diminuta in vitro. Brandford White CJ, et al. **Z Parasitenkd** 1985;71(3):365-72

TRYPTAMINES

Increased protective effect of cystamine and mexamine against radiation after activation of the haemopoiesis by dextran sulphate in mice. Vacek A, et al. **Acta Radiol [Oncol]** 1985 Mar-Apr;24(2):193-8

In vitro pigment formation from tryptamine. Role of indole-3-acetaldehyde. Das PK, et al. **Biochem Pharmacol** 1985 Aug 1;34(15):2663-7

Tryptamine-induced vasoconstrictor responses in rat caudal arteries are mediated predominantly via 5-hydroxytryptamine receptors. Bradley PB, et al. **Br J Pharmacol** 1985 Apr;84(4):919-25

Two 5-HT receptors linked to adenylate cyclase in guinea pig hippocampus are discriminated by 5-carboxamidotryptamine and spiperone. Shenker A, et al. **Eur J Pharmacol** 1985 Mar 12; 109(3):427-9

Indoleamine-sensitive adenylate cyclase in rabbit retina: characterization and distribution. Blazynski C, et al. **J Neurochem** 1985 Aug; 45(2):440-7

Tryptamine concentrations in areas of 5-hydroxytryptamine terminal innervation after electrolytic lesions of midbrain raphe nuclei. Juorio AV, et al. **J Neurochem** 1985 Aug;45(2):422-6

5-Hydroxytryptamine receptor in isolated rabbit aorta: characterization with tryptamine analogs. Clancy BM, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):761-9

Membrane responses and changes in cAMP levels in Aplysia sensory neurons produced by serotonin, tryptamine, FMRFamide and small cardioactive peptideB (SCPB). Ocorr KA, et al. **Neurosci Lett** 1985 Apr 9;55(2):113-8

TRYPTOPHAN

Plasma tryptophan, age and depression. Phipps DA, et al. **Age Ageing** 1985 Mar;14(2):71-5

An amino-terminal tryptophan derivative which is refractory to Edman degradation. Mahoney WC. **Anal Biochem** 1985 Jun;147(2):331-5

Spectrophotometric estimation of protein concentration in the presence of tryptophan modified by 2-hydroxy-5-nitrobenzyl bromide. Malin EL, et al. **Anal Biochem** 1985 Feb 1;144(2):356-61

Identification of peptides containing tryptophan, tyrosine, and phenylalanine using photodiode-array spectrophotometry. Yang CY, et al. **Anal Biochem** 1985 Feb 15;145(1):67-72

Energy transfer from tryptophan residues to pyridoxal 5'-phosphate at the active site of ribulose-1,5-bisphosphate carboxylase/oxygenase. Verma NC, et al. **Biochem Biophys Res Commun** 1985 May 31; 129(1):256-61

Effect of tryptophan metabolites on the activities of rat liver pyridoxal kinase and pyridoxamine 5-phosphate oxidase in vitro. Takeuchi F, et al. **Biochem J** 1985 Apr 15;227(2):537-44

Analysis and identification of aromatic signals in the proton magnetic resonance spectrum of the kringle 4 fragment from human plasminogen. De Marco A, et al. **Biochemistry** 1985 Jan 29;24(3):748-53

Protein structural changes accompanying formation of enzymatic transition states: tryptophan environment in ground-state and transition-state analogue complexes of adenosine deaminase. Kurz LC, et al. **Biochemistry** 1985 Mar 12;24(6):1342-6

In vitro characterization of hybrid promoters and altered tryptophan operon promoters. Russell DR, et al. **Biochemistry** 1985 Mar 12; 24(6):1410-7

Effect of tryptophan derivatives on the phase properties of bilayers. Jain

MK, et al. **Biochim Biophys Acta** 1985 Jun 11;816(1):153-62

Abilities of some tryptophan and phenylalanine derivatives to inhibit gastric acid secretion. Magous R, et al. **Biochim Biophys Acta** 1985 May 30;845(2):153-62

A controlled clinical trial of L-tryptophan in acute mania. Chouinard G, et al. **Biol Psychiatry** 1985 May;20(5):546-57

Effect of alkylation of tryptophan residues on the enzymatic and pharmacological properties of snake venom phospholipase A2. Condrea E, et al. **Can J Physiol Pharmacol** 1985 Apr;63(4):331-9

Tryptophan content of serum albumin. Kaldy MS, et al. **Comp Biochem Physiol [B]** 1985;80(4):743-5

The microbial metabolism of tryptophan in rats fed a diet containing 7.5% saccharin in a two-generation protocol. Sims J, et al. **Food Chem Toxicol** 1985 Apr-May;23(4-5):437-44

Nucleotide sequence of the Bacillus subtilis tryptophan operon. Henner DJ, et al. **Gene** 1985;34(2-3):169-77

Nutritive value of D-tryptophan for the growing pig. Arentson BE, et al. **J Anim Sci** 1985 Feb;60(2):474-9

Xanthurenic acid 8-O-beta-D-glucoside, a novel tryptophan metabolite in eye-color mutants of Drosophila melanogaster. Ferré J, et al. **J Biol Chem** 1985 Jun 25;260(12):7509-14

Analysis of the requirements for transcription pausing in the tryptophan operon. Fisher RF, et al. **J Mol Biol** 1985 Apr 5;182(3):397-409

Clues from Xanthomonas campestris about the evolution of aromatic biosynthesis and its regulation. Whitaker RJ, et al. **J Mol Evol** 1984-85; 21(2):139-49

The effect of acute lithium administration on brain monoamine synthesis and the precursor amino acids tyrosine and tryptophan in brain and plasma in rats. Berggren U. **J Neural Transm** 1985;61(3-4):175-81

Variables influencing the effect of a meal on brain tryptophan. Sarna GS, et al. **J Neurochem** 1985 May;44(5):1575-80

Lowering of plasma free tryptophan in normal and portacaval shunt dogs. Miyai M, et al. **J Surg Res** 1985 Jul;39(1):8-15

Ontogenetic studies on tryptophan transport into plasma membrane vesicles derived from rat brain synaptosomes: effect of thyroid hormones. Herrero E, et al. **Neurochem Res** 1985 May;10(5):579-89

The effects produced by prostaglandin D2 on serotonin turnover and release and tryptophan uptake. Hollingsworth EB, et al. **Pharmacol Biochem Behav** 1985 Mar;22(3):371-5

UGA is read as tryptophan in Mycoplasma capricolum. Yamao F, et al. **Proc Natl Acad Sci USA** 1985 Apr;82(8):2306-9

Fluorescence properties of insulin analogs with tryptophan substitutions. Wang ZZ. **Sci Sin [B]** 1985 Mar;28(3):264-72

TRYPTOPHAN HYDROXYLASE

Effect of clonidine on the activity of tryptophan hydroxylase from rat brainstem following in vivo or in vitro treatment. Weekley LB, et al. **Biochem Pharmacol** 1985 May 1;34(9):1549-57

Tryptophan 5-hydroxylase. Rapid purification from whole rat brain and production of a specific antiserum. Cash CD, et al. **Eur J Biochem** 1985 Jun 3;149(2):239-45

Regulation of 3-indoleacetic acid production in Pseudomonas syringae pv. savastanoi. Purification and properties of tryptophan 2-monooxygenase. Hutcheson SW, et al. **J Biol Chem** 1985 May 25; 260(10):6281-7

TYROSINE

Identification of peptides containing tryptophan, tyrosine, and phenylalanine using photodiode-array spectrophotometry. Yang CY, et al. **Anal Biochem** 1985 Feb 15;145(1):67-72

L-Phenylalanine and L-tyrosine catabolism by selected Streptomyces species. Pometto AL 3d, et al. **Appl Environ Microbiol** 1985 Mar; 49(3):727-9

Chemiluminescence in L-tyrosine-H2O2-horseradish peroxidase system: possible formation of tyrosine cation radical. Ushijima Y, et al. **Biochem Biophys Res Commun** 1985 Apr 30;128(2):936-41

Analysis and identification of aromatic signals in the proton magnetic resonance spectrum of the kringle 4 fragment from human plasminogen. De Marco A, et al. **Biochemistry** 1985 Jan 29;24(3):748-53

Formation of radiation-induced cross-links between thymine and tyrosine: possible model for cross-linking of DNA and proteins by ionizing radiation. Simic MG, et al. **Biochemistry** 1985 Jan 1;24(1):233-6

Enzymatic and nonenzymatic dehydration reactions of L-arogenate. Zamir LO, et al. **Biochemistry** 1985 Mar 26;24(7):1607-12

Elastase-cathepsin G inhibitors eglin b and eglin c differ by a single Tyr——His substitution. A micro-method for the identification of amino-acid substitution. Chang JY, et al. **Biol Chem Hoppe Seyler** 1985 Mar;366(3):281-6

Properties of the aminotyrosine derivatives of calmodulin. Steiner RF, et al. **Biopolymers** 1985 Mar;24(3):547-63

Inhibition of tyrosine hydroxylation in tissue slices of the rat striatum by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine. Hirata Y, et al. **Brain Res** 1985 Jun 24;337(1):193-6

Blood-brain barrier permeability to leucine-enkephalin, D-alanine2-D-leucine5-enkephalin and their N-terminal amino acid (tyrosine). Zlokovic BV, et al. **Brain Res** 1985 Jun 10;336(1):125-32

Hapten-specific T-cell response to azobenzenearsonate-N-acetyl-L-tyrosine in the Lewis rat. IV. Rat dendritic cells present soluble and insoluble azobenzenearsonate conjugates to T cells. Amsden A, et al. **Cell Immunol** 1985 Jul; 93(2):447-58

Bone cell phosphotyrosine phosphatase: characterization and regulation by calcitropic hormones. Puzas JE, et al. **Endocrinology** 1985 Jun; 116(6):2463-8

Tyrosine-311 of a beta chain is the essential residue specifically modified by 4-chloro-7-nitrobenzofurazan in bovine heart mitochondrial ATPase. Sutton R, et al. **Eur J Biochem** 1985 May 2;148(3):551-4

Clostridium pasteurianum glutamine synthetase mechanism. Evidence for active site tyrosine residues. Krishnan IS, et al. **FEBS Lett** 1985 Jun 17;185(2):267-71

Species variation in the tyrosine sulfation of mammalian gastrins. Andersen BN. **Gen Comp Endocrinol** 1985 Apr;58(1):44-50

Biosynthesis of chlortetracycline: Part I—oxidative metabolism of L-tyrosine by Streptomyces aureofaciens and its relation to the biosynthesis of chlortetracycline. Maladkar NK. **Hindustan Antibiot Bull** 1984 Aug-Nov;26(3-4):81-95

Structural studies of mitochondrial coupling factor 1 using tyrosine fluorescence. Fernández-Belda F, et al. **Int J Biochem** 1985; 17(2):223-8

Tyrosine sulfation of yolk proteins 1, 2, and 3 in Drosophila melanogaster. Baeuerle PA, et al. **J Biol Chem** 1985 May 25;260(10):6434-9

pH-induced hysteretic transitions of ovoperoxidase. Deits T, et al. **J Biol Chem** 1985 Jul 5;260(13):7882-8

The interaction of slow-release immunoadjuvants with selected antigens measured in vitro. Penney C, et al. **J Biol Stand** 1985 Jan; 13(1):43-52

Clues from Xanthomonas campestris about the evolution of aromatic biosynthesis and its regulation. Whitaker RJ, et al. **J Mol Evol** 1984-85; 21(2):139-49

The effect of acute lithium administration on brain monoamine synthesis and the precursor amino acids tyrosine and tryptophan in brain and plasma in rats. Berggren U. **J Neural Transm** 1985;61(3-4):175-81

Inhibition of sodium transport in frog skin and iodination of tyrosine in vitro by a peptide of renal origin. Fregly MJ, et al. **Klin Wochenschr** 1985;63 Suppl 3:102-6

N-acetyl-L-tyrosine as a tyrosine source during total parenteral nutrition in adult rats. Im HA, et al. **Pediatr Res** 1985 Jun;19(6):514-8

TYROSINE AMINOTRANSFERASE

Deletions near the albino locus on chromosome 7 of the mouse affect the level of tyrosine aminotransferase mRNA. Schmid W, et al. **Proc Natl Acad Sci USA** 1985 May;82(9):2866-9

TYROSINE HYDROXYLASE

Catecholamine microfluorometry of nigral perikarya and tyrosine hydroxylase assay in some telencephalic structures of rats exposed to different behavioral situations. Divac I, et al. **Acta Neurobiol Exp (Warsz)** 1984;44(6):262-72

Decrease in tyrosine hydroxylase synthesis in cultured adrenal medulla by N6-methyladenosine. Burke WJ, et al. **Biochem Pharmacol** 1985 Aug 1;34(15):2621-7

Effects of alpha-difluoromethylornithine on polyamine biosynthesis and tyrosine hydroxylase induction in the adrenal gland of the rat subjected to stress or apomorphine. Ekker M, et al. **Biochem Pharmacol** 1985 Apr 15;34(8):1315-20

Evidence for the involvement of Ca2+-calmodulin and cyclic AMP in the regulation of the tyrosine hydroxylase system in rat striatal tissue slices. Hirata Y, et al. **Biochem Pharmacol** 1985 Aug 1; 34(15):2637-43

Immunohistochemical evidence for phenylethanolamine-N-methyltransferase-positive/tyrosine hydroxylase-negative neurones in the retina and the posterior hypothalamus of the rat. Foster GA, et al. **Brain Res** 1985 Mar 18; 330(1):183-8

Synaptic interaction between catecholaminergic neurons and substance P-immunoreactive axons in the caudal part of the nucleus of the solitary tract of the rat: demonstration by the electron microscopic mirror technique. Kubota Y, et al. **Brain Res** 1985 Apr 29;333(1):188-92

Intrinsic tyrosine hydroxylase (TH) immunoreactive axons synapse with TH immunopositive neurons in the rat arcuate nucleus. Léránth C, et al. **Brain Res** 1985 Apr 8;331(2):371-5

The distribution of monoaminergic cells and fibers in a periventricular preoptic nucleus involved in the control of gonadotropin release: immunohistochemical evidence for a dopaminergic sexual dimorphism. Simerly RB, et al. **Brain Res** 1985 Mar 18;330(1):55-64

A comparative study of tyrosine 3-monooxygenase from rat adrenal and brainstem. Okuno S, et al. **J Biochem (Tokyo)** 1985 Jan;97(1):265-73

Purification and characterization of rat striatal tyrosine hydroxylase. Comparison of the activation by cyclic AMP-dependent phosphorylation and by other effectors. Richtand NM, et al.

J Biol Chem 1985 Jul 15;260(14):8465-73

Characteristics of tyrosine hydroxylase activation by K+-induced depolarization and/or forskolin in rat striatal slices. el Mestikawy S, et al. **J Neurochem** 1985 Jul;45(1):173-84

Appearance of the noradrenergic markers tyrosine hydroxylase and neuropeptide Y in cholinergic nerves of the iris following sympathectomy. Björklund H, et al. **J Neurosci** 1985 Jun; 5(6):1633-40

A combined autoradiographic and immunocytochemical study of 3H-corticosterone target neurons and catecholamine neurons in rat and mouse lower brain stem. Duncan GE, et al. **Neuroendocrinology** 1985 Mar;40(3):262-71

Influence of perinatal androgen on the sexually dimorphic distribution of tyrosine hydroxylase-immunoreactive cells and fibers in the anteroventral periventricular nucleus of the rat. Simerly RB, et al **Neuroendocrinology** 1985 Jun;40(6):501-10

Differential effects of transection of the spinal cord and splanchnic nerve on adrenal tyrosine hydroxylase and catecholamines. Gagner JP, et al. **Neuroscience** 1985 Mar;14(3):907-20

Morphological evidence for a dopaminergic terminal field in the hippocampal formation of young and adult rat. Verney C, et al. **Neuroscience** 1985 Apr;14(4):1039-52

Distribution of CRF- and tyrosine hydroxylase-immunoreactive neurons in the brainstem of the domestic fowl (Gallus domesticus). Knigge KM, et al. **Peptides (Fayetteville)** 1985 Jan-Feb;6(1):97-101

Sympathetic neuron density differentially regulates transmitter phenotypic expression in culture. Adler JE, et al. **Proc Natl Acad Sci USA** 1985 Jun;82(12):4296-300

[Comparative effect of the psychostimulants sidnocarb and fenamin on the tyrosine hydroxylase activity of the brain synaptosomes in rats] Ganiev MM, et al. **Farmakol Toksikol** 1985 Mar-Apr;48(2):27-32 (Eng. Abstr.) **(Rus)**

VANILMANDELIC ACID

Liquid-chromatographic determination of vanillylmandelic acid in urine. Anderson GM, et al. **Clin Chem** 1985 Jun;31(6):819-21

VASOPRESSINS

Leukotriene D4 reduces pressor responses to sympathetic stimulation, angiotensin, and vasopressin. Bayorh MA, et al. **Adv Prostaglandin Thromboxane Leukotriene Res** 1985;13:51-4

Alpha 2-adrenoceptor antagonism of vasopressin-induced changes in sodium excretion. Smyth DD, et al. **Am J Physiol** 1985 Jun; 248(6 Pt 2):F767-72

Stimulation of prostacyclin production in isolated rat adipocytes by angiotensin II, vasopressin, and bradykinin: evidence for two separate mechanisms of prostaglandin synthesis. Axelrod L, et al. **Endocrinology** 1985 Jun;116(6):2548-53

Foot shock stress-induced release of vasopressin in adenohypophysectomized and hypophysectomized rats. Knepel W, et al. **Endocrinology** 1985 Jul;117(1):292-9

Evidence for the formation of inositol 4-monophosphate in stimulated human platelets. Siess W. **FEBS Lett** 1985 Jun 3;185(1):151-6

The contribution of vasopressin and angiotensin to the maintenance of blood pressure after autonomic blockade. Hiwatari M, et al. **Hypertension** 1985 Jul-Aug;7(4):547-53

GABAergic inhibition of hypertonic saline-induced vasopressin-dependent hypertension. Brennan TJ, et al. **J Pharmacol Exp Ther** 1985 Jun;233(3):663-71

Hormonal control of renal potassium excretion. Field MJ, et al. **Kidney Int** 1985 Feb;27(2):379-87 (86 ref.)

Co-localization of corticotropin releasing factor and vasopressin mRNA in neurones after adrenalectomy. Wolfson B, et al. **Nature** 1985 May 2-8;315(6014):59-61

Senescent change in tissue weight and immunoreactive beta-endorphin, enkephalin, and vasopressin in eight regions of C57BL/6J mouse brain and pituitary. Rogers J, et al. **Neurobiol Aging** 1985 Spring;6(1):1-9

The compartmentalized hypothalamo-neurohypophysial system: evidence for a neurohypophysial action of acetylcholine on vasopressin release. Gregg CM. **Neuroendocrinology** 1985 May;40(5):423-9

Substance P, enkephalins, somatostatin, cholecystokinin, oxytocin, and vasopressin in human spinal cord. Schoenen J, et al. **Neurology** 1985 Jun;35(6):881-90

The microvasculature of the small-intestinal mucosa of the rat: quantification of hemodynamic effects of topically applied cimetidine, ranitidine, somatostatin, and vasopressin. Neff M, et al. **Scand J Gastroenterol [Suppl]** 1985;112:6-11

[Effects of diltiazem on plasma ACTH, beta-ELI and ADH levels during surgery] Kono K, et al. **Masui** 1985 Jan;34(1):18-24 (Eng. Abstr.) **(Jpn)**

VIOLENCE

The limit of violence: psychotropic drugs, law and ethics. Tamm JM. **Med Law** 1985;4(2):155-66

Behavioural and endocrine reactions in boys scoring high on Sennton neurotic scale viewing an exciting and partly violent movie and the importance of social support. Arnetz BB, et al. **Soc Sci Med** 1985; 20(7):731-6

WAKEFULNESS

Effects of acute and chronic treatment with amitryptyline on the sleep-wake activity of rats. Obál F Jr, et al. **Neuropharmacology** 1985 Mar;24(3):223-9

ZIMELIDINE

High incidence of multisystemic reactions to zimeldine. Langlois R, et al. **Eur J Clin Pharmacol** 1985;28(1):67-71

The *Psychopharmacology Bulletin* is available on subscription from the Superintendent of Documents, Government Printing Office, Washington, D.C. 20402. Subscription price $19.00 per year for the United States. All other countries add $4.75 for postage. This price was in effect at time of printing. Prices are subject to change. Please make check or money order payable to the Superintendent of Documents. An annual subscription for four quarterly issues begins with the next issue following receipt of the order. Single copies and back issues may also be ordered from the Superintendent of Documents. The expiration date is printed on the top line of the address label. Change of address and complaints about non-receipt of issues should be sent to the Superintendent of Documents and should include the old address, preferably a mailing label, as well as the new address.

The *Psychopharmacology Bulletin* is prepared by the Division of Clinical Research of the National Institute of Mental Health. Its purpose is to facilitate the dissemination and exchange of information among the national and international scientific community. This emphasis is on rapid, informal reporting of work which has not appeared in the more formal literature. In accordance with new policy set forth by our Associate Editors, we are no longer accepting unsolicited papers for publication in the *Bulletin*.

All material published in the *Psychopharmacology Bulletin* is in the public domain unless otherwise noted. Publication in the *Bulletin* therefore does not preclude publication elsewhere.

VOL. 22, NO. 1

1986

PSYCHOPHARMACOLOGY BULLETIN

Table of Contents

Annual NCDEU Meeting (1985)—Abridged Proceedings—

3 **The ECDEU- NCDEU Program**—*Jonathan O. Cole*

Re-Updates: New Perspectives on Long-Standing Issues—

7 Problems With and Promises of Monoamine Oxidase Inhibitors—*Donald F. Klein and Frederic M. Quitkin*

12 New Perspectives on Long-Standing Issues: The Monoamine Oxidase Inhibitors—*Donald S. Robinson*

16 Discussion on the Monoamine Oxidase Inhibitors—*Burtrum C. Schiele*

19 Use of Placebo in Clinical Trials—*Karl Rickels*

25 Scientific and Ethical Considerations in the Use of Placebo Controls in Clinical Trials in Psychopharmacology—*Gerald L. Klerman*

30 The Placebo Control in Clinical Trials (A View From the FDA)—*Paul Leber*

33 Pharmacological Treatments of Schizophrenia—*George M. Simpson*

36 Research Methodology and the Pharmacotherapy of the Chronic Schizophrenias—*Thomas A. Ban, William Guy, and W.H. Wilson*

42 Discussion of Dr. George Simpson's Paper on Pharmacological Treatments of Schizophrenia—*Solomon C. Goldberg*

Multicenter International Clinical Trials—

45 Introduction—*Thomas A. Ban and Jerome Levine*

47 The AMDP System in International Clinical Trials—*B. Woggon, M. Linden, H. Beckmann, E. Krebs, B. Küfferle, B. Müller-Oerlinghausen, B. Pflug, and H.W. Schied*

52 Use of a Standardized Documentation System (BLIPS/BDP) in the Conduct of a Multicenter International Trial Comparing Fluvoxamine, Imipramine, and Placebo—*Giovanni B. Cassano, Luciano Conti, Gabriele Massimetti, Francesco Mengali, Jenifer S. Waekelin, and Jerome Levine*

59 The Design and Conduct of the Upjohn Cross-National Collaborative Panic Study—*Gerald L. Klerman, James H. Coleman, and Robert P. Purpura*

Microcomputers in Clinical Psychopharmacology

65 Why a Statistical Package on a Micro?—*MaryAnn Hill*

73 Microcomputerized Testing of Drug Effects on Divided Attention—*Joe E. Thornton, Joy L. Taylor, Elizabeth L. Gibson, Terry P. Miller, and Jared R. Tinklenberg*

Benzodiazepines—New Indications—

77 The Use of Benzodiazepines for Psychotic Disorders: A Literature Review and Preliminary Clinical Findings—*George W. Arana, Marjorie L. Ornsteen, Fred Kanter, H. L. Friedman, David J. Greenblatt, and Richard I. Shader*

88 New Strategies for the Treatment of Alcohol Withdrawal—*E.M. Sellers and C.A. Naranjo*

93 Benzodiazepines for Treatment of Panic Attacks: A New Look—*Karl Rickels and Edward E. Schweizer*

Cholinergic Mechanisms in the Treatment of Geriatric Disorders—

101 Physostigmine in Patients with Alzheimer's Disease—*Michael Davidson, Richard C. Mohs, Eric Hollander, Bonnie M. Davis, Theresa Ryan, Thomas B. Horvath, and Kenneth L. Davis*

106 Intercranial Drug Administration in Alzheimer's Disease—*Robert E. Harbaugh*

110 The Cholinergic Hypothesis of Memory Dysfunction in Alzheimer's Disease—Revisited—*Nunzio Pomara and Michael Stanley*

Cholecystokinin: A Neuropeptide in the Treatment of Schizophrenia—

119 Ceruletide for Schizophrenia: A Review—*Jeffrey A. Mattes, William Hom, and Joseph M. Rochford*

123 Clinical Evaluation of Ceruletide in Schizophrenia: A Multi-Institutional Cooperative Double-Blind Controlled Study—*Hitoshi Itoh, Yasuo Shimazono, Yukio Kawakita, Yoshio Kudo, Yorio Satoh, and Ryo Takahashi*

129 Cholecystokinin: A Neuropeptide in the Treatment of Schizophrenia—*Carol A. Tamminga, Robert L. Littman, and Larry D. Alphs*

Fenfluramine Therapy for Autism: Promise and Precaution—

133 Fenfluramine Treatment of Autism: UCLA Collaborative Study of 81 Patients at Nine Medical Centers—*Edward R. Ritvo, B.J. Freeman, Arthur Yuwiler, Edward Geller, Phillip Schroth, Alice Yokota, Anne Mason-Brothers, Gerald J. August, William Klykylo, Bennett Leventhal, Kay Lewis, Leonard Piggott, George Realmuto, E. Gene Stubbs, and Richard Umansky*

141 Short-Term Efficacy and Safety of Fenfluramine in Hospitalized Preschool-Age Autistic Children: An Open Study—*Magda Campbell, Stephen I. Deutsch, Richard Perry, Barbara B. Wolsky, and Michael Palij*

148 Fenfluramine: Neurotoxicity—*Charles R. Schuster, Marilyn Lewis, and Lewis S. Seiden*

152 Fenfluramine Treatment of Childhood Attention Deficit Disorder With Hyperactivity: A Preliminary Report—*Maureen Donnelly, Judith L. Rapoport, and Deborah R. Ismond*

155 The Effects of Fenfluramine on Suicidal Behavior—*Elaine Meyendorff, Anil Jain, Lil Traskman-Bendz, Barbara Stanley, and Michael Stanley*

Free Communications—Session A—

161 The Relationship of Antiobsessional and Antidepressant Effects of Tricyclic Antidepressants—*Matig Mavissakalian, Samuel M. Turner, Larry Michelson, and Rolf Jacob*

167 A Comparison of Alprazolam and Imipramine in the Treatment of Agoraphobia and Panic Disorder—*Ross Rizley, Richard J. Kahn, Douglas M. McNair, and Laura M. Frankenthaler*

173 Taper Withdrawal Studies With Alprazolam in Patients With Panic Disorder and Agoraphobia—*John C. Pecknold and Richard P. Swinson*

177 Amitriptyline and Haloperidol in Unstable and Schizotypal Borderline Disorders—*Paul H. Soloff, Anselm George, Swami Nathan, Patricia M. Schulz, Richard F. Ulrich, and James M. Perel*

183 Open Trial of Buspirone in the Treatment of Major Depressive Disorder—*Edward E. Schweizer, Jay Amsterdam, Karl Rickels, Myron Kaplan, and Marian Droba*

186 A Review of Controlled Studies of Adinazolam Mesylate in Patients With Major Depressive Disorder—*John P. Feighner*

192 Chronic Depression: Demographic and Clinical Characteristics—*James H. Kocsis, Carlyle Voss, J. John Mann, and Allen Frances*

196 Self-Rating of Personality Characteristics and Their Relationship to Treatment Response in Recurrent Unipolar Depressives: A Pilot Study—*Ellen Frank, David J. Kupfer, David B. Jarrett, and Miriam Jacob*

200 The Suicide Assessment Scale: A Scale Evaluating Change in Suicidal Behavior—*Barbara Stanley, Lil Träskman-Bendz, and Michael Stanley*

206 A Retrospective Clinical Analysis of the Overall-Rhoades Classification of Hamilton Depression Scale Profiles—*Robert H. Lenox, Lelon A. Weaver, James E. Shipley, and Stephen Cohen*

214 Understanding the Response Lag to Tricyclics: I. Application of Pulse-Loading Regimens With Intravenous Clomipramine—*Bruce G. Pollock, James M. Perel, Michael Shostak, Seymour Antelman, Barbara Brandom, and David J. Kupfer*

220 Pharmacology of Combined Antidepressant/H_2-Blocking Drug Therapy—*Stephen H. Curry, C. Lindsay DeVane, and M. Michael Wolfe*

Free Communications—Session B—

223 Methylphenidate: Rate-Dependent Effects on Hyperactivity—*Mark D. Rapport and George J. DuPaul*

229 The Therapeutic Effect of Clonidine in Attention Deficit Disorder with Hyperactivity: A Comparison With Placebo and Methylphenidate—*Robert D. Hunt, Ruud B. Minderaa, and Donald J. Cohen*

237 The Use of MK-801, a Novel Sympathomimetic, in Adults with Attention Deficit Disorder, Residual Type—*Fred W. Reimherr, David R. Wood, and Paul H. Wender*

243 The Prevalence of Tardive Dyskinesia in a Mentally Retarded Population—*Mary Ann Richardson, Gary Haugland, Raymond Pass, and Thomas J. Craig*

250 Neuroleptic-Induced Tardive Dyskinesia and Parkinsonism: Changes During Several Years of Continuing Treatment—*Daniel E. Casey, Uffe J. Povlsen, Birgit Meidahl, and Jes Gerlach*

254 Integrating Incidence and Prevalence of Tardive Dyskinesia—*John M. Kane, Margaret Woerner, Michael Borenstein, James Wegner, and Jeffrey Lieberman*

259 A Five-Year Follow-Up Study of Tardive Dyskinesia—*Guy Chouinard, Lawrence Annable, Pierre Mercier, and Andree Ross-Chouinard*

264 Plasma Fluphenazine Levels in Patients Receiving Two Doses of Fluphenazine Decanoate—*Stephen R. Marder, John W. Hubbard, Theodore Van Putten, Edward M. Hawes, Gordon McKay, Jim Mintz, Philip R.A. May, and Kamal K. Midha*

267 An Early Phase II Clinical Trial of Remoxipride in Schizophrenia With Measurement of Plasma Neuroleptic Activity—*Guy Chouinard and L. Turnier*

272 Measuring Adverse Drug Reactions in a Postmarketing Surveillance System—*Seymour Fisher, Stephen G. Bryant, and Ronica M. Kluge*

278 Estazolam in the Treatment of Insomnia—*Roberto A. Dominguez, Burton J. Goldstein, Alan F. Jacobson, and Richard M. Steinbook*

NCDEU Workshop/Microcomputer Interest Group—

281 Microcomputer Database Management Systems Concepts—*David Robert Gastfriend*

287 SAFTEE: Data System for Side Effect Assessment Scale—*Dean J. Clyde*

288 Microprocessor-Based Assessment of Attention Deficit Disorders (ADD)—*Michael Gordon*

291 A Microcomputer-Based Psychophysiology Data Acquisition and Analysis System—*C. Keith Conners, Roy Clymer, and Robert S. Sherrick*

297 A Brain Function Diagnostic and Study Unit for Psychotropic Drug Development and Psychopharmacology Research—*Turan M. Itil, Donald M. Shapiro, Emin Eralp, Ahmet Akman, and Kurt Z. Itil*

301 BMDPC: BMDP Statistical Software for Microcomputers—*MaryAnn Hill*

307 Communications: Microcomputer/Mainframe Interfacing—*Pierre Mercier*

311 Expert Systems in Psychiatry—*Michael Feinberg and Robert K. Lindsay*

Announcements

Allen Raskin, Ph.D., Editor-in-Chief of the *Psychopharmacology Bulletin* since October 1980, has left the National Institute of Mental Health (NIMH) to become Director of the Psychology Division of Lafayette Clinic and Professor of Psychiatry at Wayne State University in Detroit, Michigan. As indicated in the masthead, he will continue his association with the *Bulletin* as "Special Features Editor."

* * *

The new Editor-in-Chief of the *Bulletin* is Nina R. Schooler, Ph.D., who has been a member of the NIMH staff active in both research and administration in psychopharmacology since 1965. In addition to her position of Editor-in-Chief of the *Bulletin*, Dr. Schooler is also Coordinator for Pharmacologic and Somatic Treatments Research and Assistant Chief of the Schizophrenia Research Branch of NIMH.

We are pleased to announce that the *Psychopharmacology Bulletin* is now being indexed and abstracted by Excerpta Medica.

* * *

ERRATUM

On page 611 of Vol. 21, No. 3, 1985, the second paragraph under *Methods* reads; "For atenolol, patients first received placebo for a week . . ." There was no placebo week, therefore it should read as follows: "Patients were simply started on atenolol, 50 mg/day. If not improved in 1 week, dosage was raised to 100 mg/day." We regret the error.

Annual NCDEU Meeting (1985)—Abridged Proceedings

The annual meeting of the New Clinical Drug Evaluation Unit (NCDEU) program of the Pharmacologic and Somatic Treatments Research Branch of the National Institute of Mental Health (NIMH) took place on May 1–4, 1985, in Key Biscayne, Florida. The program was developed by the staff of the Branch, Nina R. Schooler, Acting Chief, Jack Blaine, Robert Prien, Allen Raskin, Natalie Reatig, Joanne Severe, and Jerome Levine, former Chief of the Branch.

This was the 25th anniversary meeting of the NCDEU program. The program was established in 1959 by the NIMH as the Early Clinical Drug Evaluation Unit (ECDEU) program with 15 grantees. As described below by Jonathan Cole, the early "invitation-only" meetings for these grant-supported investigators developed into the current format of planned symposia and free communications. Sessions focus on recent research findings in psychopharmacology, methodologic problems and advances in clinical trials in this area, and updates or reviews of significant issues in the field.

The 1985 meeting had 340 attendees including 20 from countries other than the United States.

As in previous years, the Winter issue of the *Bulletin* is devoted to summaries of papers presented at the NCDEU meeting. These summaries are designed to provide early availability of the substance of the meeting to *Bulletin* readers. Publication in the *Bulletin* does not prejudice formal publication of the full papers elsewhere at a later time.

The ECDEU-NCDEU Program

Jonathan O. Cole, M.D.[1]

The New Clinical Drug Evaluation Unit (NCDEU) program had its beginning in the early days of modern clinical psychopharmacology when chlorpromazine was still controversial and psychoanalysis was still more popular and accepted than drug therapy. The National Institute of Mental Health (NIMH) had, perhaps slightly reluctantly, recognized that chlorpromazine and reserpine might be effective unique therapies and used its intramural group, led by Dr. Seymour Kety, to develop a special grant to support an evaluation of the new drugs. A major conference was developed by Dr. Ralph Gerard, then of the University of Illinois Medical School via the National Academy of Sciences (NAS), and I was the NAS staff member who did most of the leg work. The conference was held at the Statler Hotel in Washington, D.C., in September 1956 and eventually published in book form as *Psychopharmacology: Problems in Evaluation*.

About the same time, Dr. Nathan S. Kline and Mike Gorman testified to congressional appropriations committees demanding that the NIMH be given two million dollars a year in grant money to finance a multi-hospital collaborative study of drug efficacy in psychiatry. The NIMH reluctantly accepted the extra money and I was hired to run the new program, I believe because no more senior or distinguished individual was available or interested. The Psychopharmacology Service Center was created and staffed, in its early years, by Sherman Ross, Dean Clyde, Lorraine Bouthillet, Seymour Fisher, and Sol Goldberg. Gerald Klerman came on board for 2 years to help mount the original nine-hospital collaborative study of phenothiazines in acute schizophrenia.

---

[1] McLean Hospital, Belmont, MA 02178.

In those days the Program had the unique problem of having more money than it could spend. For a number of years the team of Kline and Gorman would urge Congress to appropriate still more money earmarked for research in psychopharmacology, and the NIMH administration would very reluctantly acquiesce and accept the new money. All the NIMH grant programs were rich and, believe it or not, the Mental Health Council would specially review the grants with the *lowest* 10% of the assigned priority scores to decide whether they, too, should be paid!

In this fiscal climate it was possible to propose and actually do large-scale collaborative studies, fund a major data analysis and computer facility to handle the data, and consider open-ended program support for early clinical drug evaluation units (ECDEUs).

The initial ECDEU program was designed to provide stable funding for investigators studying new drugs. Many investigators had programs functioning on fitful drug company grants and some state or Veterans Administration money. The Program was intended to provide core support for key staff and allow some kinds of research not possible on drug company money alone.

The Program was approved and advertised; eventually up to 18 such grants were funded. I believe Leo Hollister and Karl Rickels are the only Principal Investigators whose support has continued uninterrupted since the beginning of the Program. As time went by and research became more sophisticated and money got tighter, it became harder and harder for investigators to get continued support for straight-forward clinical trials of various and often unspecifiable new drugs. As review committees became more restrictive the ECDEU grant program, as originally conceived, gradually died a natural death.

However, the ECDEU meetings developed a life of their own. The meetings originally were designed to bring ECDEU grantees together with NIMH staff once or twice a year to discuss drugs they had been studying, to present data, and to compare impressions. Drug company representatives were originally excluded from the meetings entirely or invited in only when their drug was being discussed. Then there developed a second, open phase of the meeting at which drug company staff were allowed in. Gradually the meetings became totally open. Investigators who had lost grant support continued to attend, and gradually any interested investigator was welcome. The Food and Drug Administration (FDA) sent representatives, and foreign investigators often attended: two original ECDEU grantees were David Wheatley of the United Kingdom and Pierre Deniker of France. I believe the availability of this site in Key Biscayne and Burton Goldstein's willingness to continue as a semi-permanent arrangements committee, and the NIMH staff's availability as a secretariat, and the *Psychopharmacology Bulletin's* availability as a publication outlet, have all kept the meetings interesting, friendly, and productive. Jerry Levine, Nina Schooler, Allen Raskin, and Robert Prien, among others, have done a lot to keep the NCDEU meetings alive and well. They are a unique forum, more open and flexible than the American College of Neuropsychopharmacology, where investigators can exchange communications formally and informally with each other, drug company staff, and FDA staff.

The only comparable series of meetings I know of in medical research are those sponsored now by the Committee on Problems of Drug Dependence (CPDD). They go back well into the 1930's and also are attended by a mix of clinical investigators, basic scientists, drug company investigators and monitors, FDA staff, and foreign workers. Whether my early involvement with this drug abuse and analgesic testing group, then at the NAS, was influential in shaping the present NCDEU program, I cannot tell. If it was, we owe a debt to Dr. Nathan Eddy who essentially ran the CPDD program single handed for many years. He even raised money from drug companies to support free grants made by the NAS, now the CPDD, to investigators to carry out drug screening and clinical trials not committed to any particular company's drug. If federal funds continue to decrease and the drug companies to prosper, the NCDEU program could even end up trying this approach to the funding of some kinds of clinical drug studies.

In any event, I have always enjoyed and learned from NCDEU meetings. If I am partly responsible for the development of this unique and excellent program, I'm very glad. The real credit, obviously, belongs to all the participants over the years. I hope the programs are still as interesting and productive 20 years from now.

Re-Updates: New Perspectives on Long-Standing Issues

Problems With and Promises of Monoamine Oxidase Inhibitors[1]

Donald F. Klein, M.D.,[2] and Frederic M. Quitkin, M.D.[2]

We have been asked to discuss the past history of the use of monoamine oxidase inhibitors (MAOIs), the reason for the recent resurgence in interest, and the range of their demonstrated and possible clinical utility.

What are the characteristics that make for a desirable class of drugs that will incite both clinical investigation and application? A partial list would include the following:

They should be safe, especially from irreversible major side effects, such as stroke or hepatic necrosis.

Their lack of safety should not be made dramatically manifest by their being recalled from the market by the Food and Drug Administration (FDA) for deadly side effects, as occurred with tranylcypromine and iproniazid.

They should lack a wide variety of upsetting, even though reversible, side effects, such as orthostatic hypotension, insomnia, anorgasmia, erectile impairment, weight gain, and hypomania.

They should be easily explained to patients without incurring anxiety over potential catastrophies.

They should require no great modification in the patient's normal life processes. Therefore, they should not require that the patient be on a markedly modified diet.

There should be no threat of dangerous drug interactions.

There should be very clear guidelines as to just what foods or concurrent drugs incur what degree of risk.

There should be no class of drugs, such as the tricyclic antidepressants (TCAs), that are believed to be both safer and more effective for the same class of indications.

Finally, the pharmaceutical industry should believe that an investment in these agents may result in a substantial market penetration with a degree of profit which will make their efforts, in supporting clinical investigation and clinical use, profitable.

From the 1960's through the early 1970's the MAOIs failed by every one of these criteria and were generally considered both ineffective and dangerous. Therefore, they were shunned by both investigators and physicians.

We now know that the early research was flawed, primarily by low dose and inappropriate patient samples. We refer to this as a Phase II deficiency. Unfortunately, many pharmaceutical companies do not realize that controlled trials should be preceded by care-

ful study of dose ranging, latency of onset of therapeutic effect, management of toxicity, and identification of patient types responsive to the drug being studied. Neglect of these essential steps has resulted in the history of psychopharmacology being marred by the frequent release of agents at doses far too low to be generally effective and prescribed for trials of inadequate length (Quitkin et al., 1984). Unfortunately, there are no systematic guidelines to determine the necessary information before proceeding to the design of double-blind, controlled randomized trials. Shortening the time to New Drug Application approval and, therefore, lengthening the time of profitable return is often the motivation for rushing to Phase III. Unfortunately, such a rush often proves shortsighted and poor economy since inadequate Phase III studies are the outcome.

With regard to inappropriate patient samples, the widely quoted Greenblatt et al. study (1964) was generally understood to indicate that isocarboxazid (Marplan) was actually worse than placebo and that phenelzine was equal to placebo. However, this state hospital-based study did not even show imipramine to be effective. Further, in the subgroup of neurotic depressives, phenelzine was 100% effective but, since placebo was 86% effective, the drug could not demonstrate specific benefits in this inappropriate population.

A few English psychiatrists held the fort by claiming specific superiority for the MAOIs over the TCAs for a subgroup of patients they referred to as atypical depressives (Sargant, 1960, 1961; West & Dally, 1959). These patients were primarily described as having non-autonomous mood disorder associated with high levels of anxiety, hyperphagia, and hypersomnia.

In 1969, Klein described a group of patients referred to as hysteroid dysphorics. These patients are characterized by flamboyance, seductiveness, and marked vulnerability to interpersonal rejection, with dramatic crashes in mood associated with leaden paralysis, retreating to bed, and often hypersomnia and hyperphagia (Klein & Davis, 1969). This depression was, however, responsive to positive social input, such as a new boyfriend. The description of this syndrome was important because it focused attention on pathologic rejection sensitivity as a predictor of beneficial effect from MAOI. This work also suggests that some aspects of psychopathology, historically attributed to personality or character disorders, may be a manifestation of an affective disorder, and responsive to antidepressants. Unfortunately, neither the English psychiatrists nor Klein (until recently) conducted any systematic comparative trials contrasting MAOIs and TCAs in the management of such patients.

The entire field was essentially turned around by the work of Robinson, Ravaris, Nies, and co-workers (1973, 1974, 1976, 1978a,b; Ravaris et al., 1976). This team focused clearly and definitively upon the question of dosage adequacy, and identified inhibition of platelet MAO as an objective indicator of dose effectiveness.

In 1973, they published an outpatient trial using 60 mg of phenelzine versus placebo, indicating the drug was effective, safe, and well accepted (Robinson et al., 1973). In 1976 they drove the point home in a comparative study of placebo, 30 mg and 60 mg of phenelzine indicating that 30 mg was no more effective than placebo, whereas 60 mg was substantially superior to both 30 mg and placebo (Ravaris et al., 1976).

These findings made more understandable the negative report of a large study published in 1974 that had used a maximum dose of 45 mg of phenelzine (Raskin et al., 1974). In 1977 there was another positive report by Mountjoy in the English literature of the benefits of 75 mg per day of phenelzine (Mountjoy et al., 1977).

In 1979, Quitkin et al. wrote a detailed critical review of the MAOI literature that summed up the persuasive evidence for their effectiveness in what were usually referred to as neurotic depressives and even the possible benefit of these agents for endogenous depression.

The identification of subtypes of depressives who selectively benefited from MAOIs or TCAs was approached by several investigators, the most prominent being Paykel and Robinson (Robinson et al., 1981; Rowan et al., 1982). Both investigators, in a heterogenous group of outpatients, compared MAOIs, TCAs, and placebo. They found similar overall efficacy for both drugs without very much in the way of predictors of specific efficacy. This was somewhat disheartening but was consistent with the failure of statistical methodology to identify specific drug responsive subgroups from heterogeneous groups of patients.

On moving to Columbia University in 1976, Fred Quitkin, of our group, developed a Depression Evaluation Service and promptly noted that a substantial proportion of our patients fit the criteria for atypical depression. We formalized these criteria emphasizing the essential role of non-autonomous mood disturbance associated with two of four frequently associated symptoms: hyperphagia, hypersomnia, leaden paralysis, and rejection sensitivity. This prospective study comparing phenelzine, imipramine, and placebo has been underway for some years now. It includes the efforts of a large team, in particular Fred Quitkin, Mike Liebowitz, Pat McGrath, Jonathan Stewart, Judy Rabkin, and Wilma Harrison (Liebowitz et al., 1984).

In 1981, Raft and Davidson studied a small sample of depressed patients derived from a pain clinic, and showed the superiority of phenelzine to amitryptyline and the superiority of amitryptyline to placebo (Raft et al., 1981). One conceivable drawback to this study was that it was not clear whether some of the patients might have already proven refractory to tricyclic treatment.

The first report of our effort was published in 1984 on a sample of 60 patients showing, as we had hoped, that phenelzine was indeed superior to imipramine which was superior to placebo (Liebowitz et al., 1984). Sub-analysis of these groups indicated the marked superiority of phenelzine for those considered hysteroid dysphorics and also for those who had a history of panic attacks. The relevance of a history of panic attacks to phenelzine superiority was promptly affirmed by Robinson et al. (1985). We are currently analyzing the data on 120 such patients, and our previous findings hold up well.

One major question is: just what are the boundaries of the atypical depressive syndrome? Our decision to require two out of four associated symptoms was quite arbitrary. As our study progressed, we found patients who only had one or even no associated vegetative atypical symptoms and simply manifested a non-autonomous mood disturbance. We entered these patients, also, along separate tracks, into our randomized trials.

Current analyses of the data revealed similar patterns of medication response. Patients with non-autonomous mood disturbance and any of the four atypical features appear to do better on MAOI, but patients with non-autonomous mood and no atypical features did equally well on a TCA or MAOI (Quitkin et al., 1984). These analyses should be considered preliminary.

Other syndromes also share some resemblance to atypical depression. Tim Walsh, who had been studying bulimics in collaboration with Jonathan Stewart of our Depression Evaluation Service, had developed a double-blind, placebo-controlled trial on phenelzine in bulimics that seemed to indicate that phenelzine is an excellent, at least short-term, treatment for bulimia (Stewart et al., 1984; Walsh et al., 1984).

The marked rejection sensitivity of atypical depressives calls to mind the tremendous fears of humiliation and social scorn present in social phobics and, after promising preliminary studies, Mike Liebowitz is now embarked on a placebo-controlled, double-blind trial contrasting phenelzine, atenolol, and placebo in social phobics.

An important heuristic question is whether the MAOI benefit is limited to patients with non-autonomous mood disorder. Pat McGrath of our Depression Evaluation Service has conducted two small open trials on phenelzine and tranylcypromine in outpatient melancholics. These patients had approximately a 75% response rate (McGrath et al., 1984). In other trials, this patient group had placebo response rates of less than 20%. Clearly, a controlled trial is indicated in this group, also.

There are many questions that remain to be answered. Even such simple issues such as whether tranylcypromine has different effects from phenelzine has not received investigative attention. More complex are the heuristic implications raised by the development of specific inhibitors for MAO A and MAO B (Knoll, 1984). A close reading of the literature indicates that the effect of clorgyline is not clearly established (McGrath & Klein, in press). This is somewhat surprising, considering that this drug has its major effects on just those neurotransmitters that are usually considered central to depressive illness. On the other hand, in a pilot study, deprenyl appears effective in atypical depressives (Quitkin et al., 1984). This drug is now being studied in a controlled trial.

On the horizon is a new class of reversible MAOIs. How they will help our patients and our science is quite unclear to date.

Many of our patients are chronic, dating their illness from adolescence. Can their chronic, dysthymic state be reversed by prolonged MAOI treatment? Do they require chronic maintenance treatment with MAOIs or can their improved state be maintained following drug cessation? Quitkin is pursuing this issue, which has substantial public health importance, in a double-blind discontinuation trial.

To sum up, we seem to be entering a burgeoning period of MAOI research and application. That these useful agents should have been ignored for so long is an unfortunate testimonial to the peculiarities of our profit-oriented drug development system and, in particular, the problems created by Phase II failures of adequate assessment.

New Perspectives on Long-Standing Issues: The Monoamine Oxidase Inhibitors[1]

Donald S. Robinson, M.D.[2]

Monoamine oxidase inhibitors (MAOIs) fell into disuse soon after their introduction into clinical practice 25 years ago. As Dr. Donald Klein points out in the preceding paper, this class of antidepressant drug was supplanted rapidly by the tricyclic antidepressants (TCAs). The MAOIs survived in limited use with a claimed specificity of therapeutic effect for what was termed "atypical depressions" based on experience from uncontrolled studies (Klein, 1969; Sargant & Dally, 1962; West & Dally, 1959). In later controlled trials other investigators (Johnstone & Marsh, 1973; Robinson et al., 1973) confirmed the therapeutic efficacy of phenelzine in the treatment of depression. Recent studies have shown the MAOI phenelzine to be as effective as the TCA amitriptyline in the treatment of depression (Paykel et al., 1980; Ravaris et al., 1980). MAOIs are also at least as effective as existing therapies for phobic and panic disorders (Sheehan et al., 1980). There is little doubt that over the past decade this class of drugs has undergone an impressive resurgence of interest.

Application of modern clinical pharmacologic methods to the study of MAOIs played a role in this recrudescence. Studies based on strict double-blind design, careful baseline evaluation and symptom ratings, with control of critical variables, is essential to clinical psychopharmacology. The importance of these principles was appreciated relatively late in this field and has contributed to conflicting claims about various psychopharmacologic treatments, including the MAOIs.

Burgeoning interest in MAOI research over the past 10 years has resulted in documentation of their effectiveness as general antidepressants. Somewhat unexpectedly, their therapeutic spectrum seems to be broader than the TCAs. Conclusive evidence now exists also for their efficacy in anxiety disorders, including panic disorder and phobic states, and atypical affective disorders such as patients with depression with hysteroid features (Kayser et al., 1985; Liebowitz et al., 1984; Quitkin et al., 1984).

The author's involvement with MAOIs began with development of an assay of *in vivo* MAO inhibition in man which permitted monitoring of the target pharmacologic effect of these drugs in platelets of treated patients (Robinson et al., 1968). This capability proved useful in the clinical pharmacologic study of these drugs, of which relatively little was known, since FDA approval preceded the 1962 amendments to the drug laws. As a consequence, most pre-1962 drugs were lacking in basic knowledge of their pharmacokinetics, therapeutic dose range, or appropriate doses in special populations such as the elderly, and hepatic or renal-impaired patients.

At the time of their approval in 1960, studies in the rat (Gey & Pletcher, 1961) and in man (Ganrot et al., 1962) demonstrated that significant degrees of brain MAO inhibition (75% or greater) were necessary to cause an increase in tissue levels of norepinephrine, serotonin, and dopamine. However, there had been little effort in clinical trials to define adequately the therapeutic dose range, and the prior studies were overlooked. In the early 1970's this led the Vermont group to examine the relationship between platelet MAO inhibition, phenelzine dose, and clinical response of depressed patients (Ravaris et al., 1976). These clinical pharmacologic studies of phenelzine provided a replication of the earlier placebo-controlled efficacy studies (Robinson et al., 1973) and established that the dose of phenelzine is critical in

---

[2] Bristol-Myers Company, Pharmaceutical Research & Development Division, Wallingford, CT 06492.

achieving a therapeutic response. Existing labeling for phenelzine at the time called for inappropriately low doses. The lower end of the therapeutic dose range was found to be 45 mg/day. The data suggested also that the dose-response curve might not be linear. It appeared that a threshold inhibition level of at least 80% (using benzylamine as substrate) was associated with onset of therapeutic effect in depression (Ravaris et al., 1976; Robinson et al., 1978). Subsequently, dosage recommendations have been modified to be 60 to 90 mg/day for most patients.

An important question remaining to be answered is the optimal duration of treatment with an MAOI to maintain a patient in remission following treatment of an index episode. Studies are now in progress at two centers to address this critical issue. Interim results of these ongoing studies are not yet available, but there is early evidence that phenelzine treatment should be continued beyond 6 months for most patients. Selected patients with chronic or recurrent depression may require MAOI treatment for several years.

Studies have shown the optimum daily therapeutic dose of phenelzine to be approximately 1 mg/kg/body weight (Robinson et al., 1978a,b). Recent experience (Lerfald and Robinson, unpublished data) indicates that patients can be started initially at full therapeutic dosage. One would predict it should be possible to use a "loading dose" during the first week of treatment without increased risk of side effects which might accelerate the therapeutic response.

The strategy of employing a multiple fixed-dose design in Phase II studies of antidepressants is an important concept. The advantages of such designs are generation of vital dose-ranging data required for Phase III trials and clinical practice. Such dose-ranging studies, if properly designed, can also provide important efficacy data. Because of the time-consuming and expensive nature of Phase III studies, it is important to define an effective, safe dose as early as possible in the development of antidepressant drugs. Definitive, well-designed studies are key since outcome measures lack precision in psychopharmacology in comparison to many other fields of investigation, and perhaps even more critical is the temporal dissociation between initiating drug treatment, or making a dose adjustment, and the resulting therapeutic effect.

Finally, there is emerging evidence that MAOIs have specific anxiolytic effects in addition to intrinsic antidepressant activity. This possibility is supported by studies in phobic disorders (Solyom et al., 1973; Tyrer et al., 1973), depression with prominent somatic anxiety (Nies et al., 1982), depression with panic symptoms (Liebowitz et al., 1984; Robinson et al., 1985), and panic disorder (Sheehan et al., 1980). Studies by our group have shown phenelzine to have equivalent antidepressant efficacy to amitriptyline in major depression with enhanced antianxiety properties in these patients compared to the TCAs (Robinson et al., 1985). Phenelzine relieves both psychic and somatic symptoms of anxiety associated with depression.

The recent interest in serotonin as a primary neurotransmitter mediating mood and anxiety states (Peroutka & Snyder, 1980; Taylor et al., 1981) has important implications for the MAOIs. This class of drug is known to profoundly affect brain serotonin levels and to inhibit serotonergic neurotransmission (Blier & deMontigny, in press). There is increasing evidence that serotonergic systems may play a central role in modulating anxiety and tension states in conjunction with the noradrenergic systems which mediate outflow from the locus ceruleus. Anxiolytic agents, including the benzodiazepines and buspirone, share a common property of profoundly inhibiting serotonergic neurotransmission in the dorsal raphae nucleus. It is postulated that anxiety agents achieve their clinical effects by inhibiting raphae input to the septo-hippocampal system. However, buspirone, unlike the benzodiazepines, does not inhibit spontaneous firing of cells in the locus coeruleus (Sanghera et al., 1983) and actually mildly enhances noradrenergic firing. This would suggest that a decrease in serotonergic activity mediates a therapeutic anxiolytic drug effect.

An analogous situation may apply to the MAOIs which can markedly increase brain serotonin (Robinson et al., 1979) and inhibit dorsal raphae firing, in addition to their better known effects on noradrenergic systems. Current electrophysiologic and neurochemical studies may provide a basis for understanding the mechanism of action of MAOIs which probably involves a profound effect on serotonergic systems.

Summary

MAOIs are attracting intense interest, both scientifically and clinically, because of a broad spectrum of therapeutic actions. Studies support significant efficacy in the treatment of depression and anxiety disorders. Evidence from recent controlled trials, as well as clinical experience, shows MAOIs to be effective in both endogenous and nonendogenous types of major depressive disorder, atypical depression, depression with hysteroid features, and depression associated with panic attacks. In addition, MAOIs are considered to be one of the most effective treatments for panic disorder. Preliminary evidence suggests some benefit for eating disorders, social phobias, and obsessive compulsive disorder.

Relatively little is known about the need for long-term therapy with antidepressant drugs, including the MAOIs. Until the findings of ongoing studies become available, maintenance MAOI treatment should continue for a minimum of 6 months and probably longer in selected patients with chronic or recurrent depression.

At optimal dosage of phenelzine (1 mg/kg per day) an overall treatment response rate of 85 to 90% can be anticipated in major depression irrespective of subtype. Clinical pharmacology studies of antidepressant drugs can contribute to their rational use in a wide spectrum of mood and anxiety disorders.

Discussion on the Monoamine Oxidase Inhibitors

Burtrum C. Schiele, M.D.[1]

Jonathan Cole gave the keynote address in which he described how Congress was impressed in the 1950's with the great potential of chlorpromazine and other antipsychotic drugs for reducing the morbidity of mental illness. As a result, Congress gave Dr. Cole's Psychopharmacology Service Center 2 million dollars in 1956 to stimulate research. There was a paucity of good research at that time and Jon Cole and his colleagues had to "beat the bushes" for suitable grantees. This probably explains why he told me in 1959 to apply for research money, stating that "you fellows in Minnesota are doing some pretty good work." We received 1.4 million dollars in direct costs over a 12-year period and the University received as overhead about 400,000 dollars. This support resulted in over 150 clinical trials on investigational compounds. The results from most of these trials were published.

More importantly, our Early Clinical Drug Evaluation Unit (ECDEU) operation stimulated similar efforts at other centers such as the St. Paul-Ramsey Medical Center, the Missouri Institute of Psychiatry, and the Veterans Administration Medical Center in St. Cloud, Minnesota. Approximately 50 colleagues participated in these clinical trials. For many, this was a first research effort resulting in publication. Over the years, these colleagues published several hundred additional articles in psychopharmacology. Even those who did not pursue research received lasting benefits through a greater appreciation of what psychotropic drugs can and cannot do, and through familiarity with the scientific measurement of behavioral change developed by psychopharmacologists.

"New Perspectives on Long-Standing Issues" was the title of the first scientific session. Dr. Donald Kline gave a scholarly dissertation on the ups and downs of the monoamine oxidase inhibitors (MAOIs). This class of drugs historically provided the first effective modern antidepressants. The original drug, iproniazid (Marsalid), initially generated great excitement, as it appeared to have potent antidepressant action. Unfortunately, it also produced jaundice and liver damage and was removed from the American market, though it is still commercially available in Canada and the United Kingdom. A number of MAOIs were marketed but only three remain on the American scene: isocarboxazid (Marplan) and phenelzine (Nardil) are hydrazine MAOIs and tranylcypromine (Parnate) is a nonhydrazine MAOI.

The early studies evaluating the effectiveness of the MAOIs were slip-shod and poorly designed by today's standards. Nevertheless, the drugs were widely used until tricyclic antidepressants (TCAs) became available. At this time, the so-called "cheese" reaction, or hypertensive headache crisis, began to appear in patients who were taking the MAOIs. In a short time, these drugs were in disrepute and were rarely used. However, in the late 1970's there was a considerable resurgence of interest in them. This is due to the fact that better designed studies were being conducted. One of the best was a study by Dr. Donald Robinson on Nardil. He demonstrated that the effective dose level was considerably greater than what had originally been recommended, and that patients must be carefully selected. In carefully controlled trials, Nardil proved to be equal in efficacy to the TCAs. Also, a biologic measure of MAO action was available by measuring the platelet MAO content.

A second factor that created further interest in these agents was the advent of several new types of MAOIs based upon the discovery of agents that were highly selective for the two major classes of MAO, Types A and B. A selective MAOI, chlorgyline, acted on

---

[1] Emeritus Professor of Psychiatry, University of Minnesota, Minneapolis, MN 55455.

MAO-A but showed no safety advantage over the already existing MAOIs and is no longer manufactured. One of the more promising drugs is L-deprenyl, which is selective for MAO-B. MAO-A denatures norepinephrine, 5–HT, and dopamine, while MAO-B denatures dopamine and phenethylamine. L-Deprenyl apparently does not alter tyramine and, thus, is considerably less dangerous than the traditional MAOIs. It is marketed in England and other European countries as an antiparkinson drug where it is causing few difficulties and is associated with little orthostatic hypotension.

My main role in this presentation is to discuss Parnate (tranylcypromine). This agent is unlike the other MAOIs in that it has a bimodal stimulating action that occurs very quickly, whereas the hydrazine MAOIs may require several days or weeks before the antidepressant effect is apparent. Parnate has not been associated with liver troubles, tremor, or sweating as have the hydrazine drugs. In the early days, it appeared to be a drug of choice, partly because of its rapid onset of action and high potency. Before long, however, the drug began to show a higher incidence of hypertensive crisis than did the other drugs and so fell into disrepute. This was particularly true in England, where many people eat a whole meal of cheese: patients who were on Parnate often had hypertensive crises after eating ripe cheese or other tyramine-laden foods. A number suffered strokes, and there were some deaths. As a result, in 1964 the FDA threatened to seize the drug and the manufacturer removed it voluntarily from the market. Because of the large number of letters of protest, mostly from physicians who claimed to have patients who were benefiting greatly from Parnate and who had benefited from nothing else, the FDA reversed its decision and the drug was returned to the marketplace within a few months. However, severe restrictions were placed upon its use. The dose was lowered, it was not to be given to people over 60 years of age, and there was a long list of prohibited foods and drugs which should not be used while the patient was taking Parnate.

When the Drug Evaluation Scientific Inventory (DESI) studies were completed, Parnate was given a rating of less than efficacious. The rating has not been changed in spite of the fact that the manufacturer claims to have completed two well-designed studies in the last year that show its efficacy. I understand that new labeling is being developed and that the dose will be raised and restrictions lessened.

Most patients do not respond to Parnate, but it is easy to determine in a few days whether or not they will respond. Of those who do, many demonstrate dramatic improvement. To illustrate, a 43-year-old university graduate had been incapacitated by anxiety and depression for over 20 years. He had failed to respond to psychotherapy, ECT, and many new drugs and had spent the last 10 years in Anoka State Hospital. He had the good fortune to be placed on Parnate while a subject in one of our first double-blind trials under the ECDEU program. Within 3 days he was vastly improved. That Parnate was largely responsible for this improvement is supported by the fact that his fears and anxiety began to return when Parnate was taken off the market. He improved when Parnate supplies were made available to him, and went on to a complete and lasting recovery.

The aforementioned patient is a classical MAOI responder. Some responders, however, may be schizophrenic. One such patient had had florid schizophrenia for many years and had failed to obtain lasting benefit from extensive ECT, many drugs, and years of hospitalization. Surprisingly, she obtained lasting benefits from Parnate. A trial of Parnate (or other MAOI) in treatment-resistant schizophrenics who are tense and anxious or fearful may be worthwhile. A problem is that some schizophrenics may develop more florid symptomatology on Parnate, in which event the MAOI should be discontinued.

The official label says Parnate should be used only in "severe depressions." This wording needs to be improved because most of those who benefit have atypical depression, if they are depressed at all. They often have chronic fears and anxiety, and a few have frank schizophrenia or schizophrenic tendencies.

Parnate is sufficiently different from the hydrazine MAOIs and should not be lumped with these. Studies are needed to compare Parnate against the hydrazine MAOIs. If

Parnate responders would do as well on the hydrazine MAOIs, the latter may be preferred because of a somewhat better safety record.

One of my last ECDEU projects (about the time of my retirement) was an interesting study of Parnate's isomers. Commercial Parnate is a racemic mixture of plus and minus isomers. Dr. Solomon Snyder told us that animal studies suggested that the minus isomer might have greater therapeutic value and less toxicity. Our short-term trial on 11 depressed subjects indicated that he was correct. Unfortunately, as far as I know, no further studies on this intriguing matter have been carried out.

Use of Placebo in Clinical Trials[1]

Karl Rickels, M.D.[2]

It is now almost 40 years since the "Cornell Conference on Therapy" was held (Cornell Conference on Therapy, 1946). It was a "first" in medicine with its primary focus on placebo effects and double-blind methodology. In the late 1940's and early to late 1950's, Beecher and his associates conducted leading research on the patients' subjective response to active drug treatment, primarily analgesics, and to placebo (Beecher, 1955, 1959).

But it was the discovery of chlorpromazine and reserpine, two antipsychotic drugs, in the early 1950's that began to revolutionize clinical research methodology. The discipline of "psychopharmacology" was born.

Psychiatry, a medical specialty that in the early 1950's had almost rejected its medical roots and had embraced a concept of psychological and behavioral causation for most psychiatric illnesses, suddenly found itself with pharmacological tools to modify behavior significantly and to produce frequently lasting improvement. Soon, other neuroleptic agents, as well as drugs to treat anxiety and insomnia, such as meprobamate and the benzodiazepines, drugs to treat depression such as monoamine oxidase inhibitors (MAOIs) and tricyclics, and lithium to treat mania, were also introduced into medicine. The young leaders of this new field of psychopharmacology took the opportunity which was offered to them and forged ahead to develop the discipline of psychopharmacology and make it a leader in clinical research and clinical pharmacology.

The Psychopharmacology Service Center (NIMH-PSC) was created in 1956, changing its name in the early 1960's to the Psychopharmacology Research Branch (NIMH-PRB). NIMH research support multiplied and the judicious support of well-controlled, frequently placebo-controlled clinical trials, conducted both at individual research centers and as collaborative enterprises, carried out with schizophrenic, depressed, manic-depressed, and anxious patients, led to important clinical findings and to advances in research methodology not found, at least at that time, in other medical specialties. Another important driving force behind the excellent clinical collaborative research conducted in the early years of psychopharmacology was the central office of the Veterans Administration.

In these early years of psychopharmacology, industry lagged in its support of clinical research. In fact, most well-controlled studies in the 1960's were government supported. Industry had no real incentive as drugs could get approved rather easily, having to demonstrate only safety but not efficacy.

It is for this reason, but also for the fact that most schizophrenic patients lived in state hospitals and were not treated by private or academic psychiatrists, that much of the early clinical research with neuroleptics and antidepressants was conducted in relatively few State hospitals by such early leaders of psychopharmacology as Fritz Freyhan, Nathan Kline, Milton Greenblatt, Heinz Lehmann, and others.

In 1960, the first NIMH-sponsored collaborative study involving the treatment of anxious outpatients was conducted jointly by NIMH, Johns Hopkins, and the University of Pennsylvania (Fisher et al., 1964; Uhlenhuth et al., 1966), soon to be followed by in- and outpatient studies in depression.

All of these early NIMH and VA-sponsored studies employed already sophisticated research methodology, including the use of placebo and standard controls, randomization, placebo washout, and double-blind design.

[2] Stuart and Emily B.H. Mudd Professor of Human Behavior and Professor of Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

Since in psychiatry probably more than in any other field of medicine, nondrug or nonspecific factors, including the treatment milieu (Rickels, 1968), exert an important impact on treatment outcome, the use of controls, frequently placebo, became a methodological necessity. The more patients were studied, the more the phenomenon to be studied changed, the well-known Heisenberg phenomenon.

Thus interest in the placebo response in psychiatry intensified during the late 1950's and 1960's and led to a burst of publications including many by the author and his colleagues (Downing & Rickels, 1970; Downing et al., 1981; Honigfeld, 1964). Placebo controls were and are still being used primarily for two reasons: to control for effects due to suggestibility, including milieu or psychotherapy, bias, and enthusiasm of both patient and physician; and also to control for spontaneous symptom change or remission occurring while in treatment but being unrelated to the specific treatment offered.

While the use of placebo is probably more important in evaluating new treatments for anxiety, panic disorder, depression, Alzheimer's disorder, and insomnia, it also plays an important role in drug trials conducted with chronic and acute schizophrenic patients.

The appropriate use of placebo controls in psychopharmacology has been clearly defined in the Food and Drug Administration (FDA) guidelines for clinical trials of psychotropic drugs. These guidelines were drafted by a committee consisting of members of the American College of Neuropsychopharmacology (ACNP) and Early Clinical Drug Evaluation Unit (ECDEU), coming from government, academia, and industry (FDA Guidelines for Psychotropic Drugs, 1974; International Guidelines for Clinical Trials of Psychotropic Drugs, 1978; FDA Guidelines for the Clinical Evaluation of Psychotropic Drugs—Antidepressants and Antianxiety Drugs, 1978; Wittenborn, 1977). In fact, the discipline of psychopharmacology was instrumental in the development of FDA guidelines, not only for psychiatry, but also for other fields in medicine. One of the most important publications relevant to the topic at hand which resulted from close collaboration between members from NIMH and ACNP, many of them also members of ECDEU, should be mentioned here. It is edited by Jerome Levine and was entitled "Principles and Problems in Establishing the Efficacy of Psychotropic Agents" (Levine et al., 1971).

Today it is difficult sometimes to separate activities sponsored by PRB, ECDEU, or ACNP. Yet the PRB and the ECDEU are probably most closely intertwined. It is now 25 years since the ECDEU, later changed to NCDEU, was launched to bring together clinical researchers, scientists, and administrators from academia, government, and industry with the explicit goal to improve communications between those involved in psychiatric clinical research.

Another important factor contributing to improved drug evaluation methodology has been the Kefauver-Harris Amendment to the Food, Drugs, and Cosmetic Act of 1962 (Kefauver-Harris Amendments of October 10, 1962, to the Food, Drugs, and Cosmetic Act, 1962). It mandated that the FDA evaluate not only safety but also efficacy claims for any new experimental agent before approving it for general use.

As a member of the drug efficacy study (National Academy of Sciences/National Research Council, 1969) evaluating psychiatric drugs, a study which was conducted between 1966 and 1968, sponsored by the National Academy of Sciences, and which reviewed for the FDA all drugs introduced between 1938 and 1962, I became clearly aware of industry's frequent lack of interest in controlled research methodology, at times not without reason, as drugs were possibly only of marginal effectiveness. The absence of well-controlled clinical trials could again not be missed (Department of Health, Education, and Welfare, 1978) when I was chairman of the FDA Psychiatric OTC Review Panel in the 1970's.

Since clinical drug trials and the use of experimental drugs and placebo are intimately interwoven with ethical questions involving the protection of human subjects, the USPHS and the FDA independently moved ahead over the years with a number of regulations to assure subject rights and good research methodology. For example, in 1966 the USPHS published its first proposal to establish Institutional Review Boards (U.S. Public Health Service, 1966) and in 1970 the FDA published its first final rules for "Adequate and Well-Controlled Clinical Evaluations" (*Federal Register*, 1970).

Improvement of research methodology and the use of placebo parallels the increasing ethical and methodological concerns regarding the use of placebo in double-blind studies (Helmchen & Müller-Oerlinghausen, 1978).

The conduct of clinical research and the protection of human subjects has been guided since World War II by the Nuremberg Code (Office of the Adjutant General of the United States, 1947), the Declarations of Helsinki (World Medical Assembly, 1964) and Tokyo (World Health Assembly, 1975), and the Declaration of Hawaii (World Psychiatric Association, 1977). This is not to say that ethical concerns regarding clinical research and the use of placebo have not been around for some time. Sir Thomas Percival, for example, discussed placebo use in his 1803 published treatise on "Medical Ethics," and Hooper's "Medical Dictionary," published in 1811, described placebo as "an epithet given any medicine adopted more to please than to benefit the patient." Placebo controls were advocated by Dr. James Lind as early as 1753 when he evaluated the effects of lime juice on scurvy.

More recently, Beecher has given a striking example of placebo effects in surgery (1968). In the 1940's it was an in-vogue procedure to perform a ligation of the internal mammary arteries for the treatment of angina pectoris. Starting in Italy, this surgical procedure entered the United States with great enthusiasm, but when finally a controlled study was evaluated in which half the patients received ligation and the other half simply a skin incision, both groups of patients showed similar levels of improvement.

Over the years, many criticisms of the use of placebo have been voiced (Burkhardt & Kienle, 1978; Freiman et al., 1978; Editorial, 1979). Let us first discuss those voiced on methodological grounds, as placebo is frequently attacked by the statement that "everyone can break the design." To such criticism, Lasagna answered most succinctly many years ago (1971):

1. It is rare for a drug to produce side effects in all patients.
2. It is rare for a placebo not to produce side effects in some patients.
3. The production of side effects is not clearly correlated with desired therapeutic effects.
4. Analyses can always be performed to investigate the possible correlation of side effects and therapeutic success.
5. Coding can and should be done individually so that one code break does not bias all of the subsequent observations.
6. Even an obvious detectable placebo may still serve as a control for spontaneous improvement, unrelated to suggestibility which is at times the main or sole component of the placebo response.
7. Even a partial control on subject and observer bias is infinitely better than no control at all.

There do exist, however, a couple of problems when including placebo control groups. First, patients assigned to placebo studies may tend to be less ill than patients assigned to studies not including a placebo group and thus are not representative of all patients and, secondly, study enrollment will be more difficult.

What are some of the major ethical concerns?

1. Placebo use is a deception.
2. Placebo use withholds otherwise available effective therapy.
3. Placebo use actually endangers the life and welfare of the patient.

Some suggest that one can deal with some of these issues by using a small "ineffective" dose of an active drug as a control. I am against such an approach since I consider it indeed a deception of the patient.

Opponents of placebo use seem to suffer from the delusion that placebos are always ineffective and experimental drugs are always safe and effective. I personally subscribe to the statement made by Lasagna some time ago that "too often the placebo-treated patients turn out to be the lucky ones in a drug trial, deprived only of a toxic and ineffective chemical" (Lasagna, 1970). In fact, it is indeed surprising to me how frequently any, at least potentially, poisonous experimental compound will be readily prescribed to patients without great ethical concerns while a safe placebo will be considered unethical.

This lack of placebo control renders the results of many clinical drug trials meaningless, useful only for drug promotion. I subscribe to Robert Temple's view (Temple, 1984) that an "escape clause" or "easy escape" can be developed for almost any placebo application in situations where it appears to be difficult to use placebo controls for ethical and/or clinical reasons. Many examples could be quoted for such consideration. Suffice it to say that placebo has been meaningfully used in all psychiatric conditions, including schizophrenia and mania.

In some conditions, for example, instead of starting with a parallel group design, one might treat patients only with an experimental or standard agent, and then shift those responding to treatment to either placebo or continued medication. An escape clause should allow a subject to resume active drug therapy only after minimal signs of relapse occur. Such designs have certainly been successfully used in mania, schizophrenia, and depression, to mention only some psychiatric indications.

What are other control options if a placebo is not used? One is the use of "historical controls," an option which in my opinion is not very helpful in most instances. Another option is the use of dose response curves but, in my opinion, even here a placebo group is needed. Finally, the use of standard agents without a placebo control group is recommended. However, unless studies comparing an experimental with a standard agent are of large sample size, involving 100 to 200 patients per treatment cell, only positive but not negative findings are interpretable (Gillings et al., 1984). A failure to include a placebo in such trials may lead to difficulty in interpreting the results. For example, the test drug may turn out to be inferior to the standard drug. Without a placebo, however, it will be impossible to say whether the test drug has any activity at all, a question probably of interest, particularly if the experimental agent has many fewer side effects than the standard agent. In another experiment, the test drug and standard drug may perform equally well. Without a placebo control, however, one does not know whether both drugs are equally effective or ineffective, or whether one was merely dealing with an experimental sample or design unable to discriminate between treatments. Therefore, it is my considered opinion that three treatment groups, namely experimental agent, placebo, and standard agent, are necessary for most appropriate study results interpretation. Here we can compare the experimental drug against the yardstick of standard drug versus placebo response.

Once clinical efficacy has been clearly established, however, I am the last person to demand a placebo group in all additional studies. Yet I know even here of many instances in which the sponsors wished they had included a placebo group. Nevertheless, research questions such as those related to differential drug effects or safety, to the relationship of drug response and drug plasma levels, and many others can be answered without using a placebo control group.

Before concluding, allow me to cite two recent experiences pointing out the importance of placebo controls. In an ongoing trial involving alprazolam, imipramine, and placebo in agoraphobic panic patients, a patient entered the trial who, after gradual increase of dosage during the first 4 weeks, responded with full remission of symptoms, symptoms she had had for many years and which had not responded to psychotherapy and other therapeutic modalities. In fact, the patient was so much improved that she appeared together with me on a radio show and before a class of 165 medical students where she completely upstaged me. Her symptoms clearly responded to treatment and the drug in question appeared to be (to everyone concerned) alprazolam, as the patient described temporary memory problems and sedation with increased dosages but no autonomic nervous system side effects. After 8 weeks, her daily dosage was slowly decreased and when she reached half the daily dosage her symptoms returned. Once a full daily dosage was again established, the patient was symptom-free for about 4 months, at which time she began slowly to relapse, needing increasing amounts of "medication," until finally she demanded to be taken off the study and to know what she was receiving. To our great surprise, when the code was broken, the patient was found to have been on placebo. Thus for more than 4 months the patient responded significantly and better than she had ever before to the supportive milieu of a special panic disorder clinic, an effect not at all drug related.

The second example is a patient suffering from major depressive disorder of the melancholic subtype who participated in a study comparing the use of imipramine, alprazolam, and placebo in depression. The patient showed positive drug response and after the double-blind phase was over and the patient was shifted to a 1 week no-drug schedule, she called her physician 3 days later describing typical withdrawal reactions which included gastrointestinal symptoms, increased sensitivity to sound and light, increased anxiety, distress, and marked lethargy. The patient was seen at once and the psychiatrist evaluating the patient was so sure about the drug the patient was receiving that he did not even request a break of the code. He placed the patient on alprazolam for 2 weeks followed by a slow medication taper without any problems. When the study was completed and the code broken, everyone can imagine our surprise when we learned that the patient had been on placebo the whole time.

In summary, let me state unequivocably my firm belief that no psychiatric treatment method, be it a pharmacological or nonpharmacological one, be recommended for general use unless controlled studies have been conducted which clearly confirm the treatment's claimed efficacy. And in the evaluation of psychopharmacological agents this should always include at least several placebo-controlled studies, some of these also including a standard drug as a third treatment group. This statement holds true not only for the assessment of new agents in the treatment of anxiety, depression, insomnia, pain, and Alzheimer's disease, but also schizophrenia. In all psychiatric conditions, such nondrug factors as milieu change, amount of support, social and familial manipulations and many others, including the mere passage of time, do exert important treatment effects, effects which have to be controlled for in psychiatric drug trials.

Scientific and Ethical Considerations in the Use of Placebo Controls in Clinical Trials in Psychopharmacology

Gerald L. Klerman, M.D.[1]

On the occasion of the 25th anniversary of NCDEU, it is appropriate to reconsider the issues involved in the use of placebo controls in clinical trials in psychopharmacology. In the current scene, these issues involve scientific considerations and ethical problems.*

Historical Background

The theoretical and statistical basis for clinical trials had been established for many years, particularly with the work of Fisher and other British statisticians. However, it was not until after World War II that the pace of clinical research accelerated, and clinical trial designs became increasingly utilized in medicine, notably in the evaluation of treatment for cardiac problems, specifically angina pectoris, and in the evaluation of treatments for tuberculosis. Government agencies played a major role in this expansion of the use of clinical trial designs, particularly the Veterans Administration in the United States and the Medical Research Council (MRC) in the United Kingdom.

Although a few clinical trials were attempted in psychiatry in the 1930's and 1940's to assess the claims for the efficacy of convulsive therapy, insulin coma therapy, and even prefrontal lobotomy, it was not until the advent of the newer psychopharmacologic agents in the mid–1950's that clinical trials became involved in psychiatry. The rapid arrival of chlorpromazine and other phenothiazine derivatives, rauwolfia and its derivatives, and meprobamate led to intense controversy and, in partial response to that controversy, a number of controlled clinical trials were begun.

Government agencies in both the United States and the United Kingdom played a major role in organizing these trials of psychiatric drugs. In the United States, credit should be given to the Veterans Administration and also to the National Institute of Mental Health (NIMH). In the United Kingdom, the Medical Research Council initiated a number of trials.

At NIMH, the creation of the Psychopharmacology Service Center in 1956, under the imaginative leadership of Jonathan O. Cole, M.D., stimulated the development of trials, notably the Collaborative Study on the Assessment of Phenothiazines (Cole et al., 1964).

In the 1950's and early 1960's, the scientific issues of design and methodology were in the forefront. There was considerable debate as to the necessity for controlled trials. Experienced clinicians argued that controls were not necessary since they could distinguish placebo effect from drug effect and, by knowing the individual patient well, could identify the specific pharmacologic actions. Doubts were also raised about the feasibility of conducting clinical trials with psychiatric patients because of the variability of their responses, the important role of psychosocial influences on symptom fluctuation, and the absence of objective measures of psychopathology.

These issues dominated discussions in the 1950's and early 1960's, but rapidly receded through the late 1960's with the growing evidence for the efficacy of drugs and the value of clinical trials (Levine et al., 1971).

A powerful governmental impetus to the application of controlled clinical trial designs came in 1962 with the passage of the

*Dr. Rickels (this issue) has addressed the major historical background.

Kefauver-Harris Amendments to the Federal Food, Drug, and Cosmetic Act. It took 10 years for the Food and Drug Administration (FDA) to implement fully the provisions of that act. During that period, the National Academy of Sciences established the Drug Evaluation Scientific Inventory project (DESI) to review all classes of drugs approved prior to the 1962 Act, including psychopharmacologic agents. That panel was chaired by Daniel X. Freedman, then at the University of Chicago. In addition, the FDA commissioned the American College of Neuropsychopharmacology (ACNP) to participate in the guideline projects, and members of the psychopharmacologic community, through ACNP, participated in developing guidelines for the evaluation of antipsychotic, antidepressant, and antianxiety agents. These guidelines reaffirmed the necessity for controlled studies and, in particular, mandated the use of placebo controls.

By the mid–1970's, the scientific issues around the use of placebo controls subsided and ethical issues began to emerge. In the current scene, the ethical issues are predominant. There are often confounding scientific and ethical issues. Ethical concerns sometimes serve as a rationalization for avoiding the use of placebos. This is particularly so in individuals who advocate evaluating a new drug against some available drug in a two-group comparison design without necessarily using placebo.

The Scientific Consensus

It is useful at this point to restate the consensus arrived at in the 1960's. Why use placebos? Why use control groups? The placebo control group represents a control for a "package" of effects which potentially could obscure and confound the demonstration of drug efficacy.

Do placebo controls control for package of effects? These include:

1. The passage of time, particularly for patients with disorders with an inherent tendency to remit, such as acute depressive reactions, transient stress responses, adjustment disorder with mood, etc.

2. The increased attention given to the patient by the warmth, sympathy, and encouragement of the medical and nursing staff.

3. The patient's expectations and hope for improvement.

4. The psychosocial consequences of being legitimized in the sick role being given the role of patient, often has profound effects on family relations by recasting the patient's problems and behavior into an illness explanation rather than his actions being judged as badness.

In addition, there may be extensive cognitive reframing of the meaning given by the patient to his or her experience through the research interviews, rating scales, and checklists. Being asked to reconstruct the sequence of symptoms and events often gives patients a sense of meaning to the experience and serves to demystify the sequence of symptoms, distress, etc.

The multiple rating scales and checklists may serve as a form of self-monitoring, a behavioral technique shown effective in many forms of behavioral psychotherapy.

There are at least two other important reasons why a placebo control is desirable from a scientific point of view.

1. The placebo control serves as a means of calibrating the skills of the research group. In psychopharmacology, the research group and the research setting are the "instruments" for the detection of change, similar to the use of chemical instruments, such as gas chromatograph in blood assays for drugs. Just as the chemical laboratory would need to calibrate its instruments against blanks and standards on a periodic basis to maintain quality control, so the research group needs to calibrate itself to establish its sensitivity. Can this research group detect the difference between an active drug and a placebo or no-pill? Are they treating a patient population that is sensitive to drug effect? Are they adequately trained? Are they using assessment devices, including rating scales and checklists, which are capable of detecting change? There, the placebo control serves as a test of the sensitivity of the research group.

2. A placebo-washout period between the time the patients enter the study and the initiation of active drug treatment is particularly important in the current scene. In our socie-

ty, a high percentage of individuals are taking psychoactive drugs, including benzodiazepines, sedative-hypnotics, and recreational drugs. Very often patient experiences are symptomatic effects due to the pre-existing drugs, and the placebo-washout period establishes a new baseline for the amount of drug effect. This may particularly be the case in chronically ill patients who are treatment resistant, for example, the improvement noted in chronic schizophrenics when they were discontinued from maintenance treatment with neuroleptics by Paul and Lentz (1977).

Distinguishing Nonspecific Effects From Placebo Effects

Sometimes these effects are called "nonspecific" effects; sometimes nonspecific effects are equated with placebo effect.

It is desirable to distinguish within the package of nonspecific effects, that effect which may be related to pill-taking (i.e., the placebo effect). The optimum way to assess this would be a drug trial in which there was a placebo-pill group, as well as a no-pill control group and an active drug group. Where drugs and psychotherapy are being compared, there may be important reasons to employ both a placebo and a no-pill group, as has been argued by Hollon and DeRubreis (1981). Only a very few such efforts have been undertaken, most notably the trial of drugs and psychotherapy in depression by the Boston-New Haven Collaborative Group (Klerman, 1974). In that study, no effect of placebo pill-taking was noted above the no-pill situation, suggesting that there is no specific effect due to the expectation of pill-taking and prescription over and above the other nonspecific effects listed above.

Ethical Considerations

In recent years, ethical considerations have gained importance in designing trials of illnesses for which standard treatments exist, as in psychoses, or where the control group may have potential adverse effects, as, for example, "sham" electroconvulsive therapy (ECT) with induced unconsciousness, ethical considerations may preclude the use of placebos.

Space does not permit a full discussion of the constraints upon demonstration of efficacy that follow from the ethical restraints on the use of placebo groups. However, it is pertinent to identify a number of solutions that have been proposed and utilized.

On a nonscientific basis, the situation would be improved by increased interaction and communication between investigators and the Institutional Review Boards (IRBs) at their institutions. This communication should be extended to the national scene. A future conference should be planned to provide systematic interchange between scientific groups and representatives of review committees, such as the Editorial Board of IRB, or an organization such as Physician's Responsibility in Medical Research (PRIMR). This might make a useful topic for a future NCDEU meeting.

At the scientific level, a number of design options have been proposed. One is the use of a "treatment on demand" as a control. In this situation, patients are told that treatment is available to them as they feel their symptomatic state may require. Patients who exceeded a certain number of calls or visits per week are then considered treatment failures and removed from the protocol, but treatment is provided to them on a clinical basis. This option has been employed in a study on drugs and psychotherapy in acute depression (Richman et al., 1980).

Second, some investigators have allowed very liberal clinical judgment for removal from the study. Here the decision lies with the clinician. The clinician can remove the patient from the study because of concern for failure to improve, worsening in clinical condition, or adverse effects. In this design, the rate of removal from the study becomes an indirect measure of efficacy of the treatment. At the same time, the patient's clinical needs are adequately met. In order for this design to be adequately executed, it is desirable that the criteria for removal be operationally specified in advance, preferably in quantitative terms. The three categories mentioned above (failure to improve, worsening in clinical condition, adverse effects) are subject to marked variation in clinical judgment and prior agreement as to criteria in terms of rating scale change, or symptomatic or social functioning to enhance reliability and reduce variability among clinicians when the study is conducted across sites or with multiple clinicians at a single site.

Third, is the use of constructive designs. Where an established standard treatment exists, such as neuroleptic treatment for schizophrenics, constructive designs can be used. In these designs, all the patients receive the established treatment and subgroups receive the new treatments. The assumption is that the combination of the standard treatment plus the new treatment will have an additive, synergistic (cocktail) effect (Klerman, in press).

Three recently designed studies employ constructive designs in an interesting way. One, the NIMH study of strategies for the treatment of schizophrenia (Schooler and Keith, unpublished), employs a design in which all patients receive neuroleptic medication; however, the drug sample is divided into a high-dose group and a low-dose group and the design also allows for comparison of two forms of psychosocial intervention, including family psychoeducational efforts. Thus, there is simultaneous exploration of variation in drug dose as it may interact with psychosocial intervention. However, all patients are receiving neuroleptic medication based on the prior demonstration of the efficacy of neuroleptic medication.

Second, the Philadelphia study of drug dependence in the treatment of opiate dependent individuals (Woody et al., 1983) has reported the efficacy of professional psychotherapy. In this study at the Philadelphia VA Hospital, opiate dependent patients in the trial all received a "standard package" consisting of methadone maintenance plus psychotherapeutic counseling by ex-addict peer counselors. One-third of the sample received only the standard treatment, one-third received professional psychotherapy of the cognitive-behavioral type developed by Beck et al. (1979), and the other third received psychoanalytically derived supportive-expressive therapy (Luborsky, 1984). In this study, the two forms of professional therapy showed significant advantage over the standard treatment of methadone maintenance plus peer counseling.

Third, Mavissakalian (1984) has recently reported on treatment of agoraphobia in which the standard treatment involved all patients receiving instruction for in-vivo exposure. Exposure via instruction had previously been shown to have moderate efficacy, helping about 50 percent of patients with agoraphobia. Imipramine or professional exposure therapy was then compared. These constructive designs assume prior demonstration of the efficacy of the standard treatment. The standard treatment may be a drug treatment; as in the case of the schizophrenia study, the standard treatment was a neuroleptic. The standard treatment may be psychotherapy, as in the case of Mavissakalian's study of phobia, or the standard treatment may be a combination as in the Woody study, where the combination of methadone maintenance plus ex-addict peer counseling was the standard.

Conclusions

A scientific consensus has emerged as to the necessity of placebo controls in psychopharmacology. A similar consensus does not exist for psychotherapy research. It is of interest that the placebo group in psychopharmacology includes a package of social psychological factors such as the sick role, and the interaction between patient and therapist expectations. For the psychotherapy research, it is this very package of effects which is among the specific component of psychotherapy and which merits dismantling strategies (Kazdin, in press; Wilkins, 1984).

However, in the current context, the predominant issues regarding the use of the placebo controls in psychopharmacology are not scientific but ethical. The interactions between scientific and ethical considerations continue to be an important area in clinical psychopharmacology. The need exists to explore more fully the principles upon which ethical considerations constrain the use of placebo and in those instances where the ethical issues are predominant, alternative designs need to be developed. A number of promising constructed designs are being employed in conditions where standard treatments exist. The other major design innovation is the use of patient or clinician judgment for removal from the study and using the rate of removal as an indirect measure of efficacy. NIMH should consider the desirability of a conference to promote communication between bioethicists and leaders of IRBs on one hand, and clinical psychopharmacologists, statisticians, and methodologists on the other. Such a conference could provide the arena for intense discussion of unresolved problems and, hopefully, modes of their resolution.

The Placebo Control in Clinical Trials (A View From the FDA)

Paul Leber, M.D.[1]

In many quarters, placebo controls are maligned; yet, their use is virtually indispensable to the intelligent assessment of efficacy of most psychopharmacologic drug products. It is, therefore, especially gratifying to find the use of placebo resoundingly endorsed by two distinguished investigators, Drs. Rickels (1986) and Klerman (1986). Indeed, their arguments for the use of placebo are so compelling and complete that this discussion must retrace ground they have already traversed.

Federal regulations governing drug product development recognize five types of control conditions that may be employed in clinical investigations intended to meet the regulatory standard of "adequate and well-controlled" investigations (21 CFR 314.126), the standard that must be met if a trial is to be accepted as a source of "substantial" evidence of drug product efficacy. The five control conditions (i.e., placebo, dose-comparison, no treatment, active, and historical), however, vary considerably in the number and nature of assumptions required for their interpretation and, therefore, in their degree of reliability.

The historical control is highly unreliable (Sachs et al., 1982) and, therefore, considered a control of last resort in almost every area of drug development. Because the no-treatment concurrent control does not allow blinding, its usefulness in psychopharmacologic drug development is minimal. Thus, only placebo, dose-comparison, and active control designs which employ prospective and concurrent randomization of experimental and control treatments are of much use in psychopharmacology. In theory, these three designs are capable of generating equivalently persuasive evidence of efficacy; a demonstration of a difference (in the appropriate direction) between experimental and control treatments, provided it cannot be attributed to fraud, bias, or chance, must be attributed to a pharmacologic effect of the experimental drug.

However, as commonly used in psychopharmacologic drug development programs, only placebo-controlled trials have regularly provided this sort of unambiguous evidence of efficacy. Active control investigations rarely document the superiority of an experimental treatment to standard drug and, to date, experience with fixed-dose response designs is so limited that it is impossible to make any informed judgment about their potential usefulness. From a regulatory vantage point, therefore, the placebo control trial has been an indispensable tool for the assessment of psychopharmacologic drug product efficacy.

What accounts for the value of the placebo control? The placebo control allows one to distinguish between true drug effects and improvements due to 1) spontaneous remission; 2) inconstancy of illness course (i.e., if subjects are recruited at a time of symptomatic exacerbation, their subsequent improvement may reflect only a regression to the mean); 3) biased (intentional or unintentional) assessment of outcome; and 4) nonpharmacologic effects of the treatment arrangement or contract (i.e., the placebo effect, per se).

Do placebo control trials have any faults? Of course. One concern is that the very possibility of assignment to a pharmacologically inert treatment may alter the behavior of subjects and investigators in ways that may seriously compromise the external validity of the study. In particular, the chance that placebo may be assigned can affect 1) sample selection (e.g., the very ill may be systematically excluded), and 2) trial conduct (e.g., investigators may be more willing to drop patients who do not immediately respond to their assigned treatment than they would in a trial employing only "active" drugs).

Another shortcoming of studies that employ only a placebo control is that they fail to provide any data about comparative efficacy and safety. While such data are not germane to a regulatory judgment concerning efficacy, knowledge of the relative utility and risk of treatments is important for drug labeling. Moreover, the interpretation of a trial that fails to discriminate between an experimental drug and placebo can be markedly affected by knowledge of the performance of a standard treatment in that same trial. In particular, if a study fails to discriminate between the investigational agent, standard drug, and placebo, the study can be more readily discounted (i.e., it can be given lesser weight) in the agency's overall assessment of evidence bearing on the experimental drug's efficacy.

---

[1] Food and Drug Administration, Rockville, MD 20857.

Consequently, the clinical trial design that employs placebo, standard drug, and investigational drug is an ideal marriage of the placebo and active control designs. Placebo provides an estimate of what would have been had no pharmacologic treatment been given. Standard drug provides an estimate of both the intrinsic responsiveness of the patient sample to pharmacologic treatment and the sensitivity of the assay system (i.e., the investigator and his assessment methodology). The design offers the same sort of reference points as do the blank and standard solutions in a spectrophotometric analysis.

Overall, it seems fairly obvious that the placebo alone or, still better, combined with a standard drug control, is an essential tool in psychopharmacologic drug development.

This favorable view of placebo, however, is not universally held. Objections to its use have been raised on both practical and ethical grounds.

One practical objection to placebo is that it retards subject recruitment. Physicians and patients are often reluctant to forego or delay treatment with an effective drug, or even a putatively effective one, to use placebo. The objection, however, cannot be fully assessed without reference to the implied comparison; namely, what experimental design is it easier to recruit for? Unless the alternative design has a utility equivalent to the placebo design, the advantage is illusory.

Indeed, many of those who raise objections to placebo appear to assume, albeit incorrectly, that the active and placebo controls provide equivalent protection against error. If this were true, of course, there would be no justification to employ placebo. In fact, however, active controls, as commonly used in psychopharmacology, rarely provide any useful information about efficacy.

When an active control trial fails to distinguish between the effects of an experimental agent and a standard "active" control, it does *not* prove that the two drugs are equally effective. The same result might occur if both treatments were inert, if the study had inadequate statistical power, or if the study were carelessly conducted. Thus, those who argue that a finding of no difference is evidence of efficacy rely upon a series of sanguine assumptions about the conditions under which the active control study was conducted. Many of these assumptions may be unwarranted (Leber, 1985). In particular, the assumption that a standard psychopharmacologic control treatment is "active" in a particular experiment is especially tenuous. Anyone familiar with the nature of psychiatric symptoms, their intrinsic variability, and the variable nature of treatment response among psychiatric patients will recognize why.

Furthermore, the ability to detect a difference between treatments is influenced by both the size of a study and the quality of its conduct. In trials where the goal is to demonstrate a difference, it is in the interest of those who conduct them to increase power and maintain high standards of trial execution. In contrast, in trials where the aim is to fail to show a difference, the incentives, as Temple has noted (1982), are reversed.

Thus, any potential advantage in recruitment rate offered by the active control design would seem to be completely offset by its epistemological flaws. There is no advantage in carrying out a worthless study rapidly!

As noted earlier, objections to placebo are also made on ethical grounds. It seems likely that the failure to recognize the intrinsic flaws of active controls may contribute to the debate about the "ethics" of placebo use. That is, many who object to the use of placebo controls on so-called ethical grounds may do so based on the false belief that the active control is a reasonable alternative to the placebo.

In any case, there are those who believe that the use of placebo is unethical in settings where established treatments exist for the condition for which an experimental drug is being developed (Way, 1984).

This discussant finds this view inconsistent. If one believes that it is unethical to deny a patient immediate access to a known effective treatment in order to assign him to placebo, it should be equally unacceptable to delay his access to definitive treatment in order to assign him to an investigational agent which may not only be ineffective, but dangerous.

In summary, the placebo control is an indispensable tool. If it (or some reasonable substitute for it such as the fixed dose, dose-response control) were not available, we would have to approach each new drug with the skepticism expressed by the 19th century physician who advised his colleagues ". . . to treat as many patients as possible with the new drugs while they still have the power to heal." (Trousseau, quoted by Benson and McCallie, 1979).

Placebo controls are our surest protection against fads and fashions that come and go in pharmacology, against the reckless claims of therapeutic enthusiasts, and, most important, against our own mistaken beliefs and prejudices.

Pharmacological Treatments of Schizophrenia

George M. Simpson, M.D.[1]

As this is an anniversary meeting, it seems appropriate to give some information about the early clinical drug evaluation units (ECDEU), later the NCDEU. This group of investigators was created by the Psychopharmacology Research Branch (PRB) and was exceptionally important for the development of psychopharmacology in this country. In the early days of drug studies, it was reported (perhaps somewhat tongue-in-cheek) that one might receive large bottles of pills, give out handfuls of them, and report that "this is great stuff," and that was the study. Indeed, I once saw an investigator who had a pocket notebook and less than half a page of medium-size handwriting was the sum total information for each patient on his clinical trial. I might also add that his records were much superior to the other studies that I had occasion to see at that time. My own work at that time involved the notion that resting endocrinological measures would predict outcome in major mental illness, specifically schizophrenia. This was funded in the late 1950's by the PRB under the title "Research in Endocrinology and Drugs," later "The Red Project." Spin-offs from this study were trials of triiodothyronine as a treatment in schizophrenic patients with low thyroid tests who were also receiving neuroleptics, trials of Enovid in female patients who showed regular exacerbations of their psychotic symptoms thought to be associated with their menses, papers on the effects of antipsychotic drugs on reproductive function, effects of antidepressants on genito-urinary function, and a publication that showed an increase in spermatogenesis associated with the administration of a monoamine oxidase inhibitor (MAOI). On further consideration, this latter was most likely related to the fact that the two colleagues who happened to get depressed and who had been measuring their own semen count, motility, and morphology weekly for several years also drank quite a bit. The MAOIs may have been less the agent for change than the withdrawal of alcohol which was ordered during the course of this treatment.

At all events, these and other clinical trials outside the endocrinological research ward interested me and led to my applying for a grant and becoming an ECDEU member. There were many drugs available at that time and several new drugs were evaluated in the course of any 1 year. Multiple rating scales were used, many of which are seldom used today. It is not that they were poor scales but that, as ECDEU grew, the Psychopharmacology Research Branch (PRB) developed a data analysis capability, and some standardization of rating scales was essential. Thus, the Brief Psychiatric Rating Scale (BPRS) and Nurses' Observation Scale for Inpatient Evaluation (NOSIE) became standard scales. Many individual and cooperative studies were carried out by these investigators, and the science of clinical trials received a hefty shot in the arm. Diagnosis was, if not frowned on, certainly at a very primitive level in the early 1960's. One saw some very raucous and intrusive people labeled schizophrenics who were textbook manics. Perhaps because of this lack of interest in diagnosis, there were some peculiar ideas about drug actions. The idea of target symptoms was clearly a good one and was incorporated into rating scales, but there was also a notion that target symptoms were individual items and did not belong in groups to syndromes or were unrelated to diagnosis. Thus, the notion that there might be drugs specifically for hallucinations, for example, resulted in a drug marketed for that purpose—Frenquel.

Many clinical trials at this time at ECDEU units studied new drugs in chronic schizophrenic patients. The dramatic effect of chlorpromazine in an open study, coupled with the large number of hospitalized patients, made this a reasonable strategy. Hospitals had many patients who could not be discharged and who had many positive symptoms when off drugs and made mild to moderate improvement on neuroleptics. Studies invariably took 6, 8, or 12 weeks of active treatment with several weeks of no drug or placebo before and after treatment. Weekly NOSIE, BPRS, Global, and other scales were employed. It was not difficult to demonstrate in such a study that a drug was an active antipsychotic agent. All of the current antipsychotics were first tested in this fashion with the initial findings confirmed in placebo-controlled studies. It is not too surprising, if we consider that all of these drugs were developed from a similar animal model developed after the discovery of chlorpromazine, which worked so well that a variety of chlorpromazine-like drugs was developed. After the production of many, many drugs that differed in their side effects rather than in their therapeutic effects, this procedure reached a dead end. The number of new drugs diminished. There has not been a new antipsychotic drug on the U.S. market since loxapine (1975)—one of the last drugs studied collectively by ECDEU investigators. ECDEU researchers in effect received funds as an investment in them rather than in specific projects. The drop in the number of new drugs left more and more investigators with time to devote to their own pet projects which soon resembled R01 studies, e.g., our staff was involved in studying plasma levels of neuroleptics and in studying tardive dyskinesia at the time the NCDEU change took place.

---

[1] The Medical College of Pennsylvania, Philadelphia, PA 19129.

During this time, psychopharmacology progressed enormously—the sophistication of the methodology, the concern with selection of patients, diagnosis, new rating scales, inter-rater reliability, validity, etc. To an extent, the science of clinical trials which was practically nonexistent in psychiatry was now better developed in psychiatry than in any other medical specialty. Individual investigators also asked many questions about conventional drugs and produced much of the knowledge that supports present-day practices. For instance, during this period we showed that in a double-blind, controlled study one- versus three-times-a-day neuroleptic medication was equally efficacious and resulted in no increase and perhaps even a decrease in side effects if the single dose was all given at bedtime. Later, we studied the same phenomenon but also measured plasma levels. We studied fluphenazine decanoate and showed that it was active at 12.5 mg every 2 weeks. We showed that patients in general responded similarly to repeated administrations of medication, that patients who gained weight did so on each occasion, and patients who did not gain weight did so on both occasions. We showed that the immediate symptoms of withdrawal of antipsychotics were mainly related to the concomitant withdrawal of anti-parkinson agents. Therefore, a patient receiving a neuroleptic plus an anti-parkinson agent should not have both withdrawn simultaneously; the anti-parkinson agent should be continued for at least 1 week in order not to have an upsurge of extrapyramidal reactions. In 1968, we studied "the behavioral and anti-epileptic effects of an iminostilbene derivative," one of the earliest studies of Tegretol in a psychiatric population; and in 1967, a preliminary evaluation of the sedative effects of Catapres, a new antihypertensive agent in chronic schizophrenic patients. A series of papers on extrapyramidal side effects (EPS) resulted in the development of a rating scale for EPS. From this and other studies came our interest in trying to cut down the very high dose of drugs that psychiatrists used and continue to use. In these studies, it appeared that doctors used 300 percent more neuroleptics than were required. In the 1960's began the studies of lithium, studies of naltrexone in chronic schizophrenia, studies of antipsychotics in the elderly, studies with clozapine, and so on. Each ECDEU would have a similar range of different studies that they carried out, all of which added to our knowledge of psychopharmacology.

Nearly all of the investigators were active in teaching and training and so, to a large extent, these units reached a stage where they were perhaps no longer necessary, i.e., there were groups of young psychiatrists who were now being trained in psychopharmacology, the journals were replete with good studies to be read in journal clubs, etc. The introduction of clozapine raised new hopes for the type of different drug that everyone had been looking for, and this remains a not-impossible dream but certainly an unrealized one. In the meantime, use of neuroleptics has advanced the treatment of schizophrenia. It is safe to say that without neuroleptics, social psychiatry and the community mental health movement would have had great difficulties in coming about. The surge of interest in psychosocial treatment of schizophrenia highlights this, since clearly psychosocial interventions are helpful but are not very helpful in the absence of neuroleptic agents. Thus, this anniversary of the ECDEU truly represents the end of a cycle in the search for new treatments in schizophrenia. A substantial advance has been made in the treatment of schizophrenia and, while we have far to go, I feel secure that NCDEU investigators will be in the forefront of the advances to come.

Research Methodology and the Pharmacotherapy of the Chronic Schizophrenias[1]

Thomas A. Ban, M.D., William Guy, Ph.D., and W.H. Wilson, Ph.D.[2]

Introduction

Schizophrenic disorders occur in 0.86% of the general population. This implies that 86 out of 10,000 people randomly chosen from the general population will develop a schizophrenic disorder during their lifetime (Tsuang & Vandermey, 1980). Almost half of all patients diagnosed as schizophrenic will need long-term treatment, and it has been estimated that 30 to 60% of all new long-term patients suffer from one or another form of schizophrenia (Mann & Cree, 1976). There is evidence that 15% of patients who are diagnosed today as suffering from a schizophrenic disorder will become chronically hospitalized at some time in the future. Consequently, it is estimated that one-third to one-half of all psychiatric beds, i.e., one-sixth to one-fourth of all hospital beds—since nearly 50% of all beds are psychiatric—are occupied by schizophrenic patients (Todd et al., 1977).

The prevailing treatment modality for patients with chronic schizophrenia is pharmacotherapy with neuroleptics. This is to the extent that, in a multi-national survey carried out in 768 chronic hospitalized schizophrenic patients, 739 or 96.2% were treated with one or more of 33 different neuroleptics. The total population of this study was contributed by nine centers geographically located in eight countries (Tables 1 and 2) (Ban et al., 1984b).

In spite of their extensive use, it is difficult to demonstrate the therapeutic effectiveness of neuroleptics in chronic schizophrenic patients. This may be due to the lack of sensitive instruments for the assessment of change in this population. An alternative possibility is that chronic schizophrenia consists of a biologically heterogeneous population. In favor of this latter contention is the fact that not every schizophrenic patient shows a similar response to neuroleptics.

TABLE 1

Number and Percentage of Patients Receiving One or More Neuroleptics

Country	*N*	Neuroleptic *N*	Neuroleptic %
Brazil	95	71	74.7
Hungary	59	58	98.3
Italy	93	90	96.8
Japan	200	200	100.0
Nigeria	10	10	100.0
Panama	86	86	100.0
USA	150	149	99.3
Yugoslavia	75	75	100.0
Total	768	739	96.2

TABLE 2

Thirty-Three Neuroleptics Employed in Eight Countries (rank order)

1–11	12–22	23–33
Haloperidol	Promazine	Methylperidol
Chlorpromazine	Clothiapine	Oxypertine
Levomepromazine	Loxapine	Mesoridazine
Thioridazine	Pimozide	Alimenazine
Fluphenazine	Carpipramine	Trifluoperidol
Perphenazine	Perazine	Clopenthixol
Thiothixene	Reserpine	Molindone
Trifluoperazine	Floropipamide	Spiperone
Sulpiride	Fluspirilene	Moperone
Clozapine	Butaperazine	Fluphenazine Decanoate*
Propericiazine	Flupenthixol	Fluphenazine Enanthate*

*The long-acting preparations are not included in the ranking.

Demonstration of Therapeutic Efficacy

Demonstration of therapeutic efficacy is one of the prerequisites for the introduction of a new treatment modality into clinical

---

[2] Department of Psychiatry, Vanderbilt University Medical Center, Nashville, TN 37217.

practice. For drugs which are not causal treatments for a particular disease, e.g., neuroleptics for schizophrenia, this represents a methodological problem which includes the development of an appropriate experimental design and the employment of a discriminative instrument for the measurement of change. It is important that the assessment instrument employed in the measurement of change have the necessary sensitivity to demonstrate differences between the new treatment and the untreated course of the disease (placebo) at the accepted level of probability.

The most frequently employed instrument in the assessment of neuroleptic-induced changes in chronic schizophrenic patients is the Brief Psychiatric Rating Scale (BPRS) (Overall & Gorham, 1962) which consists of 18 items scored on a 7-point scale of intensity.

Since an essential prerequisite for the usefulness of the BPRS in chronic schizophrenic patients is the necessity that the majority of the 18 items (symptoms) be present in a considerable percent of the target population, we have reviewed our data to determine the presence of 18 psychopathological symptoms corresponding to the BPRS items in the same population of 768 patients (Ban et al., 1985).

Data were collected with a specially devised instrument, the Psychopathological Symptom Profile (PSP), developed from the Psychopathological Assessment form of the second edition of the AMP-System by adding items from the Present State Examination (Wing et al., 1974), the Schedule for Affective Disorders and Schizophrenia (SADS) (Spitzer & Endicott, 1978), and on the recommendation of special consultants. The PSP consists of 176 psychopathological symptoms and includes most items of the Psychopathological Symptoms section of the English edition of the AMDP–III System (Guy & Ban, 1982). Each item is followed by a brief definition and is scored from 0 to 3, indicating whether the symptom is definitely absent (0), probably absent (1), probably present (2), or definitely present (3). Accepting scores 2 or 3 as "present," it was revealed that, of the 176 symptoms of the PSP, 33 were present in at least 40% of the 768 patients (Table 3). We chose the 40% as cutoff point on the basis that any symptom present in a lower percent would not be a useful item in the assessment of change. As shown on Table 4, 8 of the 18 BPRS items are included among the 33 most frequently encountered symptoms of the PSP. While these represent some of the most frequently encountered symptoms of schizophrenia, it is clear that there are a number of significant symptoms which are simply not encompassed by the BPRS. A differently structured instrument would be more suitable in the assessment in order to avoid the possibility of covering up therapeutic changes (Type II or β error) resulting from the administration of neuroleptic drugs.

TABLE 3

Psychopathological Symptom Profile (The 33 Items Present in 40% or More of the 768 Patients)

Rank	Item	N	%
1	Lack of insight	717	93.4
2	Blunted affect	632	82.3
3	Asocial behavior	606	78.9
4	Delusions	561	73.0
5	Autistic	553	72.0
6	Unkempt	515	67.1

Shortcomings of Classification

Introduction of neuroleptics, the most effective single treatment modality employed in chronic schizophrenic patients, has brought attention to the differences in therapeutic responsiveness among patients. In spite of this recognition, which suggests that chronic schizophrenia consists of a biologically heterogeneous population, examination of the nature of this heterogeneity, by studying the natural course of the disease with special emphasis to the end-state syndromatology of patients, has been given little attention This is especially surprising since there is little, if any, evidence that patients with different types of schizophrenia as classified by the Diagnostic and Statistical Manual—3rd ed., 1980 (DSM–III) or ICD–9 respond differentially to neuroleptic drugs, while there are indications for differential responsiveness in the different subtypes (end-states) described in Leonhard's (1979) classification of chronic schizophrenias. This complex classification which distinguishes 19 distinct syndromes belonging to two groups of disorders within the schizophrenias has shifted emphasis from the acute to the chronic forms of the illness. Leonhard maintains that schizophrenic disorders can best be studied after the acute manifestations common to all schizophrenias have subsided and the illness has progressed into its disease-specific final form (Ban, 1982) (Table 5).

By employing Leonhard's classification, Fish, as early as 1964, found that 117 out of 123 nonsystematic schizophrenics (95%) showed a favorable therapeutic response, while only 289 out of 351 systematic schizophrenics (69%) showed a favorable response. From both a practical and a theoretical point of view, however, the important findings were that among the nonsystematic patients, the favorable therapeutic response was rated marked to moderate in 79% of the treatment responsive patients, while among the systematic patients only 23% were so rated. Fish also noted that, among the nonsystematic patients, those suffering from periodic catatonia responded less favorably than patients with affect-laden paraphrenia and especially

TABLE 5

Leonhard's Classification of Chronic Schizophrenias

Nonsystematic			Systematic		
Cataphasia	Affect-laden Paraphrenia	Periodic Catatonia	Paraphrenias	Hebephrenias	Catatonias
			Phonemic	Autistic	Parakinetic
			Hypochondriacal	Eccentric	Proskinetic
			Confabulatory	Shallow	Speech-prompt
			Expansive	Silly	Speech-inactive
			Fantastic		Manneristic
			Incoherent		Negativistic

cataphasia; among the systematic patients, therapeutic responsiveness was not evenly distributed among the three major classes of illness. Thus, while as many as 40% of the paraphrenics showed a moderate or marked therapeutic response to neuroleptics, only 23% of the hebephrenics and 0.9% of the systematic catatonics showed a similar response.

Corresponding with these findings are our observations and results. We have reported on a patient with the diagnosis of periodic catatonia (febrile catatonia), a nonsystematic subtype, in whom an increase in neuroleptic dosage was associated with exacerbation, a decrease in dosage with amelioration, and discontinuation of medication with remission of psychopathological symptoms (Kelwala & Ban, 1981a). In another case report of two patients with diagnoses of shallow hebephrenia, a systematic subtype, discontinuation of neuroleptic medication had no detectable effect for an extended period (Kelwala & Ban, 1981b). Thus, in our two shallow hebephrenic patients, the usefulness of maintaining neuroleptic treatment was questionable; in our periodic catatonic patient, neuroleptic treatment seemed to have a negative therapeutic effect.

The notion that neuroleptic treatment in certain patients may not just be ineffective but may actually be harmful received further substantiation in our survey of 24 patients treated with lithium/neuroleptic combinations. A common characteristic of these patients was that they had previously shown insufficient therapeutic response to neuroleptic drugs alone. Analyses of data revealed that 9 of 10 patients of the nonsystematic population exhibited a favorable therapeutic response to the combination, while 9 of 14 systematic patients showed no response or an unfavorable therapeutic response. In addition, 5 of the 24 patients developed neurotoxicity during the course of treatment; 2 of the 5 patients were silly hebephrenics and 1 each belonged to the expansive, fantastic, and confabulatory subtypes of paraphrenia. While 5 out of the 14 patients with systematic schizophrenia manifested neurotoxicity, none of the 10 patients with nonsystematic schizophrenia, predominantly affect-laden paraphrenia, developed a similar undesirable response to the lithium/neuroleptic combination (Prakash et al., 1982).

Most important in this context are the findings regarding tardive dyskinesia in our multi-national survey (Ban et al., 1984a). While the overall prevalence rate for the population was 11% when determined by clinical judgment and 13% when determined by the Research Diagnostic Criteria for Tardive Dyskinesia (Schooler & Kane, 1982), within the Leonhard system, rates were found to be significantly lower in the therapeutically more responsive nonsystematic group (4.3%). Furthermore, while within the systematic catatonias, the manneristic subtype (53 patients, 32.7%) attained a prevalence rate of 28% and, within the systematic hebephrenias, the silly subtype (56 patients, 19.1%) had a prevalence rate of 53%, within the paraphrenic category, in the expansive (14 patients, 5.4%) and confabulatory (6 patients, 2.3%) subtypes, tardive dyskinesia was not encountered at all. On the basis of these findings, one may hypothesize that there is an inverse relationship between positive symptoms and adverse effects of the neuroleptic drugs at least insofar as tardive dyskinesia is concerned. Since there is no indication that the action mechanism of neuroleptics would be different in patients belonging to different diagnostic groups, one may speculate that, in the development of tardive dyskinesia, not just the administered drug but the biology of the host also plays an important role.

Concluding Remarks

One of the most important contributions for psychiatry which has resulted from psychopharmacologic progress is the recognition that schizophrenia consists of a biologically heterogeneous population. In view of this, it is rather paradoxical that identification of the role of dopaminergic structure in the action mechanism of neuroleptics and demonstration that neuroleptics produce dopamine receptor blockade led to speculations about the nature of schizophrenia in terms of dopamine excess which, in turn, provided sufficient incentive to develop a large number of "me-too" neuroleptics with similar therapeutic but somewhat different adverse effect profiles.

Ignoring the biological heterogeneity of chronic schizophrenia has created considerable difficulties for research in this population, while its recognition has provided new endpoints for preclinical research especially useful for drug development. One tangible result of this research is the introduction of a new category of psychotropic drugs, referred to as "les produits de transition" (transition compounds) in France.

Included among these substances are amoxapine, a dibenzoxazepine which combines the pharmacologic profile of a tricyclic antidepressant with a neuroleptic: carpipramine and chlorcarpipramine: tricyclic dibenzazepines with butyrophenone side chains: and carbamazepine, an anticonvulsant structurally related to the cyclic antidepressants. While the old methodology should suffice for the demonstration of therapeutic effectiveness of these drugs, the identification of the therapeutically responsive populations may require the employment of new diagnostic assessment instruments.

It is a common contention that psychopharmacology has opened unforeseen possibilities for psychiatric progress leading to a reintegration of psychiatry with other medical disciplines. Reevaluation of psychiatric concepts with consideration to psychopharmacologic contributions could open unforeseen possibilities for psychopharmacologic progress with a shift of emphasis from simple therapeutic efficacy based on statistical probabilities to the identification of therapeutically responsive chronic schizophrenic patients to specific treatment modalities.

Discussion of Dr. George Simpson's Paper on Pharmacological Treatments of Schizophrenia

Solomon C. Goldberg, Ph.D.[1]

In the earlier days of neuroleptics, there was substantial success in treating chronically hospitalized or chronic ambulatory schizophrenic patients. Unfortunately, most of the chronic patients who remain now are treatment resistant. They are a poor sample of patients on which to test new antipsychotic drugs whose mechanism is dopamine blockade. Indeed, they can lead to misunderstandings concerning the effectiveness of neuroleptics in schizophrenia if these patients are employed in a test of neuroleptic effectiveness. Paul's work (1972), in which he failed to find a drug effect in chronic schizophrenic patients, was interpreted by him to mean that antipsychotic drugs in general were not effective in chronically psychotic patients. His error was in generalizing from his results to other situations in which standard antipsychotic drugs are effective in the treatment of many schizophrenic patients. These nonresponders to dopamine blockers become prime candidates for the testing of other antipsychotic agents. We are morally obligated to try to find some treatment that will help these patients. This thought has occurred to a number of investigators, and nonresponsive patients have been tried on such agents as propranolol, alprazolam, carbamazepine, lithium, and *d*-amphetamine.

Before starting a patient on one of these agents, it may be well to confirm that the patient is indeed a nonresponder to standard neuroleptics. State hospitals are notoriously conservative in their dosing strategies because of self-protective policies which prohibit the administration of doses higher than those recommended by the *Physician's Desk Reference*. Prien and Cole (1971), for example, found a substantial number of patients who profited from very high doses of phenothiazines after not responding to standard doses.

In a nearby state hospital we are exploring lithium and carbamazepine for the treatment of neuroleptic nonresponders. There has been no difficulty in getting such patients transferred to our unit. When the patients arrive, they are almost invariably on a variety of medications, and our first step is to taper them from these while building them up on a dose of fluphenazine HCl. The fluphenazine dose is increased for 2 weeks until there is no further improvement or until side effects intervene. So far we have found a few patients who are responders to higher doses of fluphenazine, and they are no longer regarded as nonresponders. Those who do not respond become candidates for our trial drugs, but not on a double-blind clinical trial basis. We feel that this is premature until we generate some hypotheses regarding the characteristics of those who will profit from them. The formal clinical trial of any of the new drugs is postponed until a later time.

If a patient is a complete nonresponder to neuroleptics, he is first put on a trial of lithium alone. If he is a partial responder, he would be put on a combination of lithium and his neuroleptic, which in this case would be fluphenazine. If he does not respond to the first medication, he automatically is then given a trial of carbamazepine. On a case study basis, the characteristics of responders and nonresponders to the different drugs are observed.

Beyond the empirical search for new treatments for nonresponders, there is the more theoretical question of why some schizophrenic patients do not respond to neuroleptics. Here there is another line of research which proposes that the schizophrenic nonresponder shows evidence of organicity. There are now at least two studies, Weinberger et al. (1980) and Schulz et al. (1983), showing an association between enlarged ventricles on the CT scan and nonresponse to neuroleptics. These studies were partly an outgrowth of the Johnstone (1976) and Crow

---

[1] Director of Psychiatric Research, Medical College of Virginia, Richmond, VA 23298.

(1980) hypothesis to the effect that schizophrenic patients with negative symptoms have enlarged ventricles and do not respond to neuroleptics. Murray and his associates (in press–b) go a step further to indicate that the schizophrenic with organic signs has a low genetic loading by virtue of family history for schizophrenia, has a history of birth complications involving signs of asphyxia, and was born in a winter month, implying a greater likelihood of viral infection. Murray, in a recent editorial in *The Lancet* (in press–a), proposes that the time has come to recognize two major etiological types of schizophrenia, a genetically transmitted disorder, and a nongenetic disorder whose etiology is more likely environmentally induced brain damage.

What was begun as an empirical search for new treatments for nonresponders has developed a theoretical facet to try to explain the differences in the characteristics of responders and nonresponders. The heuristic value of the theoretical orientation is that it may be capable of suggesting why some of the new treatments may be effective. For example, Slater's (1963) cases of epilepsy who showed schizophrenic symptomatology might be most treatable with the anticonvulsant carbamazepine. To borrow a phrase from social science, "There is nothing so practical as a good theory."

Introduction

Thomas A. Ban, M.D.,[1] and Jerome Levine, M.D.[2]

The multi-center approach has been used in clinical psychopharmacology since the late 1950's. Collaborative studies coordinated by the United States National Institute of Mental Health (NIMH), United States Veterans Administration, and the United Kingdom Medical Research Council contributed to the establishment of proper usage of antidepressant and neuroleptic drugs. Without employing a multi-center approach this would have taken considerably longer, and generalization of the findings would have encountered considerably greater difficulties.

Multi-center clinical trials are particularly advantageous for studying the effect of psychotropic drugs in rare disorders. But even in common disorders such as Alzheimer's type of dementia, if one aims to study a homogeneous sample with progressive deterioration at a particular stage, only in a multi-center clinical trial can one expect to find an adequate number of suitable patients within a reasonable period of time.

International participation adds another dimension to multi-center clinical research. Such studies have at least three essential prerequisites: 1) multidimensional description of patient's condition, because of the possible differences in diagnostic practices among participating centers in different countries; 2) assessment instruments in the measurement of change which are reliable and valid across cultures; and 3) feasibility of coordination for making operational the collaboration.

In this session, findings in three multicenter international clinical trials will be presented, one carried out with an antipsychotic (fluperlapine), another with an antidepressant (fluvoxamine), and the third with an anxiolytic drug (alprazolam).

The topic of the first paper is the AMDP System in International Clinical Trials: A Report on Fluperlapine. The AMDP System stands for Arbeitsgemeinschaft für Methodik und Dokumentation in der Psychiatrie or, in English, Association for Methodology and Documentation in Psychiatry. It was founded in 1965 by a group of psychiatrists from Germany, Switzerland, and Austria to develop a uniform system for the documentation of information which would be useful in both clinical practice and psychopharmacologic research. Since the Psychopathological Symptom Form, the instrument employed in the assessment of change in the AMDP was developed with emphasis on form, i.e., the mode by which the patient encounters contents, and as such is not contaminated by social-cultural contingents, and should be particularly suited for international collaborative psychopharmacologic research.

The first paper dealt with an international multi-center clinical trial with an antipsychotic, the second dealt with an international multi-center clinical trial with an antidepressant. Professor Cassano and his colleagues presented findings from a multi-center international trial comparing fluvoxamine, a specific serotonin reuptake inhibitor with imipramine and placebo. It should be noted that in all the different phases of this study a modification of the Biometric Laboratory Information Processing System usually referred to as BLIPS has played an important role. This system was developed at the Biometric Laboratories of George Washington University in collaboration with the Psychopharmcology Research Branch of NIMH under the leadership of one of us (J.L.). This system, which has played an important role in the development of clinical trial methodology in the United States, has been implemented in Europe, where Dr. Cassano and his colleagues have created an even more versatile system, BLIPS/BDP.

The third paper by Dr. Klerman and colleagues presents, for the first time, the results of Phase I of the Upjohn worldwide panic disorder study.

In addition to the results of these studies, this session demonstrates the different ways in which multinational trials can be organized depending on the roles played by the sponsors, investigators, and the availability of computer-based data documentation and analysis systems.

The AMDP System in International Clinical Trials: A Double-Blind Comparison of Fluperlapine and Haloperidol

B. Woggon,[1] M. Linden,[2] H. Beckmann,[3] E. Krebs,[4] B. Küfferle,[5] B. Müller-Oerlinghausen,[2] B. Pflug,[6] and H.W. Schied[7]

Introduction

One important methodological problem in international collaborative studies is the selection of suitable rating scales. The translation of a psychopathological rating scale is complicated by different concepts of psychopathological symptoms and syndromes in different languages and countries. The Association for Methodology and Documentation in Psychiatry, a collaborative group of German, Swiss, and Austrian psychiatrists, was founded in 1965 and the first AMP manual was established in 1971 (Angst et al., 1969; Scharfetter, 1971). Based on broad clinical experience, many drug trials, and a number of methodological studies, a revision of the AMP system was completed in 1979, called the AMDP System (Association for Methodology and Documentation in Psychiatry) (AMDP, 1979, 1983). The AMDP System is currently available in many languages including German, Croatian, English, French, Russian, Spanish, Japanese, Portuguese, Greek, Italian, Danish, and Dutch.

This paper is composed of two parts: a) a description of the AMDP System; and b) an example of an international collaborative trial: a double-blind comparison of fluperlapine* and haloperidol in schizophrenic patients that utilizes the AMDP System.

Description of the AMDP System

AMDP consists of five integrated parts, each printed on a single sheet of paper: 1) demographic data; 2) life events; 3) psychiatric history; 4) psychopathological symptoms; and 5) somatic signs. The 100 psychopathological symptoms and 40 somatic signs are clearly arranged into groups, an aid for the rater (Tables 1 and 2). It is also possible to add write-in items of specific interest to a clinical trial.

Each symptom can be rated as "absent," "present," or "not ascertained." A symptom is rated as "not ascertained" if reliable information is not available. If a symptom is present, three degrees of severity can be rated: mild, moderate, or severe. This judgment is based on frequency, intensity, and duration of a symptom.

Each rating of psychopathological and somatic symptoms is based on a specified time period, for example 24 hours, and combines

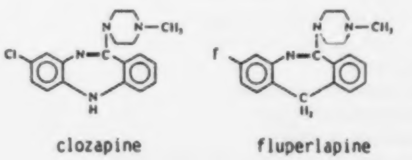
both subjective (reported) and objective (observed) information.

Factor analyses of data from various patient samples have led to the development of subscales representing psychopathological syndromes. For statistical analyses of data from clinical trials, different sets of subscales can be used. A comprehensive monograph in English that describes the system includes studies of subscales, interrater reliability, validity, and sensitivity in drug trials (Bobon et al., 1983).

Double-Blind Comparison of Fluperlapine and Haloperidol

As an example of the use of the AMDP System in an international collaborative trial, we report preliminary results of a double-blind study comparing fluperlapine and haloperidol. Fluperlapine (a dibenzazepine) is very similar in structure to clozapine (Figure 1). In open trials, it showed a strong antipsychotic effect (Angst, 1984).



clozapine fluperlapine

FIGURE 1. Chemical structures of clozapine and fluperlapine.

Seven psychiatric hospitals participated in the study, four in the Federal Republic of Germany, two in Switzerland, and one in Austria. These hospitals are linked to the AMDP and, therefore, the investigators and staff are familiar with and trained in the use of the AMDP System.

The following results are based on data from 120 inpatients who were randomly assigned to treatment with either fluperlapine ($N = 60$) or haloperidol ($N = 60$). Some patient characteristics are given in Table 3; diagnoses according to the ICD-9 (International Classification of Disease) are given in Table 4. The planned duration of treatment was 28 days. Early dropouts (before day 7) were excluded from the final analysis.

Using a flexible dose regimen, the recommended initial daily dose was 2.5 mg haloperidol or 50 mg fluperlapine, three times a day. Maximum daily dose was 60 mg haloperidol and 800 mg fluperlapine. At the end of the trial, the average daily dose was 23 mg haloperidol (s.d. = 12 mg) and 441 mg fluperlapine (s.d. = 210 mg).

Data analysis was performed at the Department of Psychiatry of the University of Zurich, Switzerland, using a set of 13 subscales (Table 5). Raw scores of the subscales are calculated by adding the included items according to the following values: absent and

not ascertained = 0; mild = 1; moderate = 2; and severe = 3. In order to normalize the distributions, logarithmic transformations were performed for the scores of subscales 1 to 12. The scores of subscales 13 and 14 are nearly normally distributed and do not require transformation. Because the number of items in each syndrome is different (range 7 to 27), all scores are further transformed ($\bar{x} = 50$, s.d. = 10, range 20-80).

The analysis of the Hallucinatory-Disintegrative syndrome clarifies the antipsychotic efficacy of fluperlapine and haloperidol. The symptoms are listed in Table 6. Table 7 shows mean values and s.d. for the syndrome on each rating day. Significant reduction during treatment occurred in both treatment groups [Friedman's analysis of variance (ANOVA)]. The comparisons between day 0 and subsequent rating days in each group separately indicated a significant improvement beginning on day 3. Because of multiplicity of significance, *t* tests were done; and alpha was adjusted from 5% to 1% (Figure 2).

T tests between the two treatment groups on each rating day revealed no significant differences. An analysis of covariance (ANCOVA) following the model for factorial experiments with repeated measurements, and constant covariates (unequal cell frequencies) was calculated using the scores at day 0 as a covariate (Winer, 1962). No significant differences between the two groups were found.

We predicted a difference in extrapyramidal side effects between the two treatments. The subscale that includes extrapyramidal symptoms is the Neurological Syn-

drome (Table 8). Mean values and s.d. of this syndrome in both treatment groups are listed in Table 9. A significant change over time in the group treated with haloperidol was found (Friedman's ANOVA). Comparison between day 0 and the following rating days demonstrated a significant increase in the haloperidol-treated patients from day 3 onward (Figure 3). *T*-test comparisons at each rating day showed no difference between the groups at pretreatment. From day 3 on, the haloperidol-treated patients had significantly higher values than the fluperlapine-treated group in this syndrome. The ANCOVA showed a significant difference between the two groups.

Use of a Standardized Documentation System (BLIPS/BDP) in the Conduct of a Multicenter International Trial Comparing Fluvoxamine, Imipramine, and Placebo

Giovanni B. Cassano, M.D.,[1] Luciano Conti, M.D.,[1] Gabriele Massimetti, M.D.,[1] Francesco Mengali, M.D.,[1] Jenifer S. Waekelin, M.D.,[2] and Jerome Levine, M.D.[3]

Introduction

When in 1978 Duphar BV, Holland, decided to organize a multicenter international clinical trial with the aim of assessing efficacy and safety of a new selective serotoninergic antidepressant compound, fluvoxamine maleate (FUVOX), the BLIPS/BDP system (Biometric Laboratory Information Processing System/Data Bank for Psychopharmacology), used at the Center for Clinical Psychopharmacology Data Documentation (CCPDD) of the Institute of Clinical Psychiatry of the University of Pisa, appeared to provide the necessary underlying structure for the study by offering an efficient standard data documentation system.

The organizational model that was used for the study provided that the company would maintain their usual role in the selection of sites, monitoring and collecting data, and supplying drugs to the sites. The role of the Pisa center included consultation on the design of the study, choice of the rating scales, and provision of a standardized documentation and analysis system, namely the BLIPS/BDP.

The company provided the raw original data collected from the investigators to the CCPDD. They organized several meetings with principal investigators in which the Pisa center participated, but the Pisa center had no additional contacts with the participating investigators.

The advantages of this organizational model include: a) open choice of sites and investigators (investigators do not need to belong to a previously organized group); b) the company plays its usual role with regard to site selection and monitoring; and c) the BLIPS/BDP documentation and analysis system does not require the use of special purpose (trial specific) rating scales but only the use of a standardized identification block. Therefore, widely used rating scales can be utilized by investigators without the necessity of special training, only checks of interrater reliability. This results in a very cost-effective flexible model which, as we will show, is sufficiently sensitive to establish efficacy and safety.

Material and Methods

The planned "Duphar" trial was an international multicenter, double-blind, prospectively randomized clinical trial aimed at comparing the antidepressant activity and safety of FLUVOX with that of imipramine (IMI) and placebo (PBO) in in- or outpatients aged over 18 years and suffering from a major depressive illness (according to the DSM-III definition).

Initially, there were 12 participating centers, 7 in North America and 5 in Europe (Table 1). FLUVOX and IMI, in unit doses of 50 mg, and PBO, in indistinguishable capsules, were administered according to a fixed-flexible dosage schedule: one capsule the first day, two capsules the second day, and three capsules from the third to the seventh day. After the first week the dosage could be adjusted, according to clinical judgment, from a minimum of one to a maximum of six capsules per day and administered, where possi-

[f] Placebo-controlled study conducted under the same protocol: data not included in the analysis.

ble, three times a day. No other psychotropic medications were allowed with the exception of chloral hydrate or flurazepam, as hypnotics, only when this was unavoidable.

Patients with an established diagnosis of major depressive illness and with a score of at least 15 on the first 17 items of the Hamilton Rating Scale for Depression (HAM-D) at the end of the pretreatment period, and not precluded by the exclusion criteria (childbearing potential or pregnant women; antidepressant therapy in the past 2 weeks; electroconvulsive therapy within the last month; depressive symptoms secondary to other psychiatric illness; dependence upon licit or illicit drugs; serious organic diseases; need for concurrent medications which could interact with the study drugs or obscure their effects; and patients unwilling or unable to cooperate in the study) were included in the trial.

After a pretreatment period of 3 to 7 days, during which one capsule of PBO indistinguishable from the treatment capsules was given, patients received drugs for up to 28 days. For the North American centers, the treatment period was extended to 42 days. Analyses presented here are focused on 28-day data in order to utilize both European and North American data.

Assessment instruments were mostly the standard rating instruments of the BLIPS/BDP and the assessments were done on entry, at the last pretreatment day, and weekly thereafter (Table 2).

The main aim of this paper is to demonstrate the utility of the organizational model for this kind of study. Because of that, we will consider only the Adult Personal Data Inventory (APDI) for the demographic data, the Patient Termination Record (PTR) for the trial data, the HAM-D and the Clinical Global Impression Scale (CGI) for efficacy data, and the Dosage and Treatment Emergent Symptoms Scale (DOTES) and Treatment Write-in Scale (TWIS) for safety data.

Results

Of the 12 participating centers, only 8 furnished sufficient data for analyses (Table 2). Three centers (Nos. 3, 4, and 7) studied inpatients; all the others studied outpatients. Two North American centers (Nos. 8a and 8b) and one European center (No. 9) have been excluded from the analyses because of the small number of patients enrolled. Due to a delay in obtaining permission to conduct the trial

from the Italian authorities, the Pisa center (No. 10) conducted a separate PBO-controlled trial under the same protocol; the Pisa data are not included in these analyses.

Of the 481 enrolled patients, 448 had at least two evaluations during the drug intake period (Table 1) and have been included in the APDI, PTR, and DOTES analyses.

The distribution of the patients according to their major demographic characteristics (APDI)—age, sex, marital status, prior treatments, significant medical conditions, and previous hospitalizations—is approximately the same in the three treatment groups. The less-than-1-year duration of the actual episode is less (but not significantly so) in the PBO group (Table 3).

Data from the PTR (Table 4) provide significant differences among the three groups. The duration of treatment is approximately the same, but the reasons for premature termination differ significantly between active drugs and PBO. As can be expected, in the PBO group premature interruptions for ineffectiveness are relatively more frequent than in the two active drug groups, whereas the opposite is true for the adverse reactions. There were no differences among the groups in the number of patients requiring hypnotics, but a trend in suggesting mainly that patients on active drugs required more gastro-

intestinal preparation. To the question: "Given the choice, would you continue on this study medication?" the investigators' answer is significantly in favor of the two active drugs.

The mean daily dosage of the three treatments is similar in both the week-by-week analysis and in the overall treatment period. Maximum dosage is reached in the third week (Table 5). The most frequent side effect (rated at least moderate) observed in the FLUVOX group is "nausea." "Dry mouth," "sweating," and "dizziness" are more frequent in the IMI group (Table 6).

These preliminary findings allow us to discriminate between the two active compounds and PBO and, on the basis of side effects, to differentiate FLUVOX from IMI.

At this point, rather than describe further the standard output of the BLIPS/BDP system, we would rather emphasize the flexibility and potential for rapidly and easily looking at the data in different ways. We will demonstrate the possibilities offered by the BLIPS/BDP system in handling and analyzing the pooled data of a large multicenter trial.

The major statistical procedure employed in the following analyses was a two-way analy-

*The Efficacy Index from the CGI combines a global rating of improvement and side effects.

sis of covariance ANCOVA where drug conditions and centers were the two factors in the design. For the efficacy data we performed two types of analyses "in parallel": the first includes all patients with at least two evaluations on drug (the so-called "intent-to-treat analysis"); the second method, which we call "efficacy analysis," is limited only to cases with at least 14 days' medication and not withdrawn after the 14th day because of possible study drug-related concurrent signs and symptoms, or for reasons unrelated to study drug (Table 1). With the BLIPS/BDP system, it is possible to perform the two types of analysis, one immediately after the other, by simply giving the computer the different selection criteria.

The score on the CGI item "severity of illness" is approximately the same in the three treatment groups (intermediate between "moderately" and "markedly ill") at the beginning of the treatment; the final score is close to "mildly ill" for FLUVOX and IMI and close to "moderately ill" for PBO in the intent-to-treat analysis. In the efficacy analysis, these differences are more marked and they reach the statistical significance in favor of the two active compounds (Table 7). Although significant differences were found between centers (Centers 2 and 3 in both analyses, Centers 3 and 6 in the efficacy analysis), no interactions between centers and drugs emerged.

For the CGI item "global improvement" the improvement is greater with FLUVOX and IMI than with PBO, but the statistical significance is reached only in the "efficacy analysis" where the FLUVOX- and IMI-treated patients are rated approximately "much improved" and the PBO-treated patients rated "minimally improved" (Table 8). The results of Center 2 are significantly different from all other centers except for Center 7, but no significant interactions between centers and drugs exist.

At the end of treatment, the number and percentage of patients judged as "much" or "very much improved" are greater in the FLUVOX and IMI groups than in the PBO group. These differences are greater (chi-square analysis) in the efficacy analysis (Table 9). The analysis of the CGI item "efficacy index" seems to favor FLUVOX over PBO and especially over IMI (Table 8).

TABLE 9

CGI — Global Improvement: Number and Percentage of Improved Patients

		Intent-to-Treat Analysis				Efficacy Analysis			
		FLUVOX	IMI	PBO	Total	FLUVOX	IMI	PBO	Total
Much or Very Much Improved	No.	84	72	53	209	79	65	51	195
	%	52.2	48.3	37.1	46.1	65.8	54.6	41.5	53.9
Minimally Improved	No.	31	32	38	101	20	22	34	76
	%	19.3	21.5	26.6	22.3	16.7	18.5	27.6	21.0
No Change or Worse	No.	46	45	52	143	21	32	38	91
	%	28.6	30.2	36.4	31.6	17.5	26.9	30.9	25.1
Total		161	149	143	453	120	119	123	362

The above examples give an idea of the utility of the BLIPS/BDP system in analyzing data derived from clinical trials of psychotherapeutic agents. However, the flexibility of this system enables us to perform many other analyses with very few additional simple external commands.

If, for instance, we want to study how the initial severity influences the results of treatment, we can stratify patients according to the initial severity on a selected assessment instrument and analyze the resulting groups as new cohorts. In this example, we used the initial HAM-D total score as an index of severity. In this study, 25.75 is the mean initial total score of the HAM-D and 5.72 the standard deviation (SD). We therefore consider "mildly" severe patients to be those with a score less than or equal to 20 (mean minus SD), "severe" patients with scores equal to or more than 31, and "moderately" severe patients with scores between 21 and 30. The ANCOVA (in this case drug conditions and level of severity are the two factors in the design) demonstrates that the pattern of improvement is almost the same for all analyzed items and factors (CGI and HAM-D). The improvement, however, is greater for the FLUVOX- and IMI-treated patients than for the PBO-treated patients. As is clearly seen in Table 10, the greater the initial severity, the greater is the improvement.

TABLE 10

	I	2.54	.98	61.4
	P	2.63	1.44	45.2
Outpatients	F	2.18	1.26	42.2
	I	2.05	1.38	32.7
	P	2.14	1.69	21.0
Total Sample:				
Inpatients		2.65	1.20	54.7
Outpatients		2.12	1.45	31.7***

F = Fluvoxamine: I = Imipramine: P = Placebo
*Adjusted scores.
**Covariance analysis: $F > P$ - $p < 0.05$
$I > P$ - $p < 0.05$
***Covariance analysis: Inpatients > Outpatients - $p < 0.05$

As both inpatients and outpatients are included in this trial, one of the obvious analyses would be the comparison of results between the inpatients and the outpatients. With very few instructions, we stratified patients according to the treatment setting and again ran the two-way ANCOVA. The results demonstrate that the initial severity of the analyzed items and factors on CGI and HAM-D is higher in the inpatients than in the outpatients. This is shown in Table 11. For the HAM-D "retardation" factor, these differences are statistically significant.

Conclusions

In this paper, data from a multicenter international clinical study on FLUVOX have been presented to exemplify both the problems raised and the potential information that can be obtained using a comprehensive and standardized system of analyses.

The BLIPS/BDP standardized output provides a clear profile of FLUVOX from its efficacy to its safety through the comparison with IMI and PBO. Drug and center interactions, when present, are immediately in evidence, as well as possible limitations and inadequacies of the design or of the conduct of the study.

Once the cleaned data are stored in the computer data bank and processed, the first standard analyses can be presented to the principal investigators. This will stimulate suggestions for specific analyses. Multicenter trials, because of the number of subjects and centers, offer the possibility of a more complete study of a drug's profile as well as of the population in the study, and of the instruments employed in the ratings. In this way, there can be a complete exploration of the data which provides not only psychopharmacological information but also information on clinical, psychopathological, epidemiological, and transcultural aspects of the population under study. The BLIPS/BDP accomplishes this by a completely automated procedure, capable of answering a wide array of questions. Moreover, the standard outputs can be interpreted with great facility because they are in a uniform format.

Frequently, investigators collect data which are grossly underused in terms of the clinical information being analyzed. For this reason, we strongly recommend that multicenter clinical studies should be planned with a view to using an established proven data handling, processing, and documenting system.

In conclusion, we have shown that a multicenter international study can be successfully accomplished using customary pharmaceutical industry procedures and monitoring linked to an established standardized documentation system.

The Design and Conduct of the Upjohn Cross-National Collaborative Panic Study

Gerald L. Klerman, M.D.,[1] James H. Coleman,[2] and Robert P. Purpura, M.D.[3]

The decision by the Upjohn Company in the early 1980's to initiate a large and complex study came from two scientific developments: 1) new developments in understanding the psychopathology, diagnosis, and classification of anxiety disorders, and 2) the early experience with alprazolam, a new triazolobenzodiazepine.

New Developments in Psychopathology, Diagnosis, and Classification of Anxiety Disorders

The continuum model of anxiety (as shown in Figure 1) had been the dominant view of anxiety states for many decades. This model proposed a continuum from normal fears and tension through intermediate stages of stress reactions, to full-blown anxiety neurosis (whose most severe form was agoraphobia). From World War I through the 1970's, most clinicians, whether of biological, behavioral, or psychoanalytic persuasion, accepted this continuum model of anxiety. This model emphasized the gradients of severity and was built upon the experience of anxiety and fear in everyday situations and in adaptation, and evolution.

This model drew upon the psychological research of Cannon (1936) on "fight or flight" and his demonstration of the role played by the autonomic sympathetic nervous system. Later, biological research was extended by Selye to include the hypothalamic-pituitary-adrenal-cortical system as a mediator of "stress."

In the 1960's, a number of observers challenged this continuum view. Roth and associates (1960) in England described the "phobic-depersonalization syndrome," sometimes called the "calamity syndrome." West and Dally (1959) and Sargant (1960) described a group of atypical depressives with predominant anxiety symptoms who appeared responsive to monoamine oxidase inhibitors (MAOIs). In the United States, Klein and his associates (1964) described the failure of chlorpromazine to influence severe phobic anxiety and reported that imipramine, tricyclics, and antidepressants improved panic episodes and agoraphobia.

Further research demonstrated the value of two classes of antidepressant drugs: MAOIs and tricyclic antidepressants, in contrast to the limited efficacy of conventional benzodiazepines (Sheehan, et al., 1980).

As a result of these observations, the proposal was made (*see* Figure 2) to separate agoraphobia and panic disorder from other forms of anxiety disorders and to group these conditions together. These proposals were partially embodied in the Diagnostic and Statistical Manual—3rd ed., 1980 (DSM-III) classification of Anxiety Disorders, which represented a significant departure from previous U.S. classifications as in the DSM-I, DSM-II, ICD-8, and ICD-9.

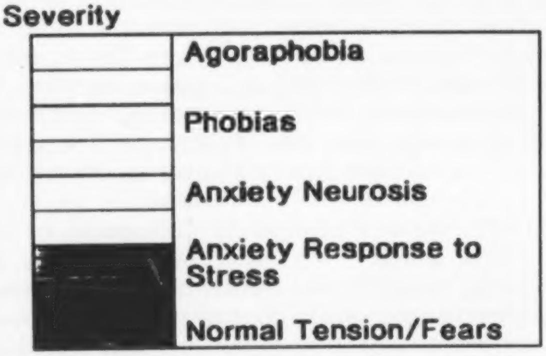

FIGURE 1. Continuum of anxiety.

[3] Medical Manager, Psychopharmacology Research Unit, The Upjohn Company, Kalamazoo, MI 49001.

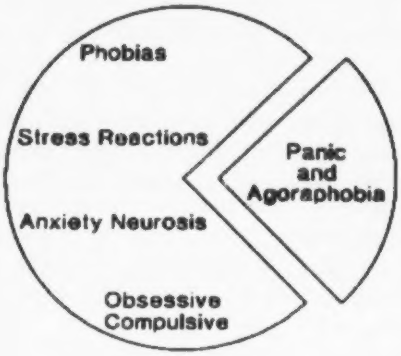

FIGURE 2. Panic and agoraphobia—separated.

In this new view, the central feature of the clinical psychopathology is the panic attack. The panic attack involves not just greater intensity of anticipatory anxiety, fears, and tension, but is a discrete time-limited episode with sudden onset of intense dread, accompanied by bodily symptoms suggestive of automonic arousal such as sweating, palpitations, tremor, and fear of losing control, going crazy, fainting, or dying.

There has been considerable controversy around the nosologic status of panic attacks, but also a continuing disagreement over the relative roles of drug treatment, MAOIs, tricyclics, beta-blocking agents, benzodiazepines, and also the efficacy and role of behavior therapy, particularly desensitization and exposure in vivo and flooding.

Alprazolam: A New Triazolobenzodiazepine

The chemical structure of alprazolam represents a modification of the conventional benzodiazepine ring structure by the addition of a triazolo group to the ring. The Upjohn Company developed a number of triazolo compounds, notably triazolam (Halcion) and alprazolam (Xanax). Trazadone (Desyrel), which has demonstrated antidepressant action, is also a triazolo compound.

Preliminary reports by Chouinard et al. (1982) suggest the value of alprazolam in panic disorder and agoraphobia, and these observations were confirmed in two controlled trials reported by Carr and Sheehan (1984).

The evidence presented by Ballenger at this meeting indicates the efficacy of alprazolam over placebo in the acute treatment of panic attacks and agoraphobia. Still unresolved is the question of the relative efficacy of alprazolam against other benzodiazepines, particularly diazepam. Experienced clinicians who have worked with patients with panic and agoraphobia are of the opinion that the efficacy of alprazolam is far superior to that of other benzodiazepines. Most patients entering recent trials with MAOIs, alprazolam, and tricyclics have had extensive prior treatment with benzodiazepines with limited success.

Should further studies demonstrate the superiority of alprazolam to other benzodiazepines, in what way can we account for this action of alprazolam? The efficacy of alprazolam in panic disorder could be due to pharmacokinetic or pharmacodynamic mechanisms.

There are suggestions that alprazolam has pharmacodynamic effects on the down-regulation of beta-blocking receptors. If substantiated, this pharmacologic profile of alprazolam would share certain similarities with antidepressant drugs such as tricyclics. Alprazolam has been effective in mild to moderate forms of depression, but not in severe endogenous, melancholic, or psychotic forms (Laakmann, in press).

The differences between alprazolam and other benzodiazepines may be pharmacokinetic. Assuming a ten-to-one equivalence between diazepam and alprazolam, 6 to 8 mg of alprazolam, the dose used in studies of panic disorder, would be the equivalent of 60 to 80 mg per day of diazepam, a dose which is seldom tolerated by most ambulatory patients.

Studies comparing alprazolam with diazepam at equivalent doses are underway and should help resolve this question.

Goals of the Upjohn Cross-National Panic Project

In 1982, the Upjohn Company initiated a worldwide panic program (Purpura, in press) which includes a number of interrelated pharmacologic, biologic, and clinical studies. Within the large program, the Cross-National Collaborative Panic Study focuses on clinical efficacy and safety.

The major goal of the Cross-National Panic Study is to assess the efficacy and safety of alprazolam in the treatment of panic disorder and agoraphobia. Subsidiary goals include: 1) better understanding of the psychopathology and diagnosis, and 2) improved means of diagnostic assessment and of evaluation of change in clinical trials of anxiety disorders.

Another subsidiary goal is to develop improved collaboration between industry, academic medical centers and universities, and governmental agencies in the U.S. and other countries.

To achieve these goals, the Cross-National Project is being conducted in two phases.

The *First Phase*, eight centers collaborating on the common design, which involves a comparison of alprazolam versus placebo, has been completed and results are being reported today. The eight centers are shown in Table 1 and include five in the U.S. (New York City, N.Y.: Iowa City, Iowa; Torrance, California: Rockville, Md.: and Charleston, S. Carolina), two in Canada (Montreal and Toronto), and one in Melbourne, Australia. Over 500 patients have been studied for an 8-week period in these eight centers. The dose schedule was a fixed, flexible dose with the attempt that all patients receive 6 mg per day of alprazolam, a dose considerably higher than previously used in studies of anxiety and depression. Diagnostic consistency is accomplished by the use of the Structured Clinical Interview for DSM-III Diagnosis (SCID), developed by Spitzer and Williams (unpublished).

In the *Second Phase*, alprazolam is being compared against placebo and against a standard drug, imipramine. The choice of imipramine as a standard drug was a difficult one, inasmuch as no drug treatment has been approved by the FDA for this condition. In the case of depressions, the tricyclic drug is the standard drug. In the case of beta-blocking agents for cardiovascular illness, propranolol is the standard drug. However, in the case of panic disorder and agoraphobia, no drug had been approved by the FDA, and there was no consensus in the field as to what should be the standard drug; conventional benzodiazepines, such as diazepam (Valium), a tricyclic, or an MAOI. Imipramine was chosen because of the extensive evidence for its efficacy (Liebowitz, in press).

This Second Phase of the study is now underway in 12 countries, and by the spring of 1986, approximately 1,000 patients will have been entered into treatment.

The First Phase and Second Phase studies utilize the same diagnostic criteria (modified from DSM-III), the same structured interview (SCID-up), and the same battery of scales and ratings for the assessment of clinical improvement and adverse effects. All data are encoded on upscan forms and sent to a central data processing facility in Kalamazoo, Michigan.

Assurance of Diagnostic Standardization and Quality Control

In any clinical trial, attention must be given to standardization of procedures for the selection of patients, randomization, assessment of change, control of concurrent medication, etc. In multicentered trials, particularly those which involve more than one nation, these considerations become all the more paramount. In addition, in this trial, since there was some degree of controversy over the validity of the diagnostic concept of panic disorder and its relationship to agoraphobia, considerable attention had to be given to the techniques to assure standardization of diagnostic assessment.

Among the techniques utilized, the following are noteworthy:

1) A very detailed protocol and procedures manual was prepared. The attempt was made to anticipate as many contingencies as possible, so as to provide explicit instructions to

the investigators, and to increase the likelihood that the study would be conducted in a similar way at all eight sites.

2) To ensure diagnostic consistency, a modification of the DSM-III criteria for panic attack, panic disorder, and agoraphobia were developed as part of an ongoing consensus project among the investigators at the eight sites, and involve a large group of consultants who have been active in the field.

3) A structured interview, the SCID-up, was commissioned for the explicit purpose of standardizing the interview procedure, so as to reduce information variance and criterion variance. Drs. Spitzer and Williams at the New York State Psychiatric Institute and Columbia University, College of Physicians and Surgeons, developed the SCID-up to operationalize the criteria for the study, including inclusion and exclusion criteria. The SCID-up has been translated into a number of languages for the participating countries in phase two, and extensive training and reliability exercises have been conducted.

4) A 1-week training workshop was held in Boston in 1983 for the first-phase investigators, and in Pisa, Italy, in November of 1983 for the second-phase investigators. During this training exercise, the protocol was reviewed in great detail, the concept and criteria for panic attack and agoraphobia were discussed extensively, video tapes were viewed, the SCID-up was explained, and experience was gained in the use of the SCID-up in interviews with patients from local clinical settings.

5) Special attention was given to provide operational definition and systematic assessment of panic attacks. Since the reduction of panic attacks was the major outcome of the study, it was necessary to devise a new instrument. Based upon Dr. Sheehan's previous experience, with assistance from consultants (particularly Drs. Spitzer and Williams), a detailed assessment of panic attack was devised which incorporated distinctions between spontaneous and unexpected panic attacks and situationally provoked panic attacks and limited symptom attacks, and these were further distinguished from anticipatory anxiety. In addition to the physician-guided ratings, each patient completed a weekly log in which daily records were kept of the number, intensity, and duration of attacks, medication taken, and activities outside of the home.

6) As a further assurance of systematic standardization in quality, a quality assurance program was instituted in which teams of two consultants not directly involved in any of the clinical sites were recruited and trained and then made on-site visits to each of the sites at least twice during the conduct of the trial. During these visits, the records were reviewed for diagnostic consistency, and interviews with patients were observed and assessed.

Organization of the Study

The overall project, including the two phases, is coordinated by Mr. Coleman and Dr. Purpura of the Upjohn Company. I serve as a consultant.

In addition, there is a *Study Review Committee* chaired by Dr. Daniel X. Freedman which operates similarly to operations committees in VA cooperative studies, namely, it is unblinded and periodically reviews the progress of the study and evidence as to indices of safety and efficacy, in order to terminate a study for ethical reasons either because of the adverse effects which pose risks to the patient or the evidence of overwhelming efficacy which would lead to compromising the needs of patients exposed to placebo. This group also advises informally on matters of research design, statistics, and interpretation of findings.

For each two phases of the study, a *steering committee* composed of the senior investigators and co-chaired by Mr. Coleman and Dr. Klerman meets periodically to review decisions and protocol, to plan data analyses, and to monitor progress. In addition to the meetings two or three times a year, monthly teleconference calls provide for ongoing discussion of issues in the conduct of the trial, management of possible complications, and to ensure data processing and data analysis.

Training sessions have been held for each phase. The phase-one investigators met in Boston, Massachusetts in February 1983, for 1 week to review the protocol and to obtain training and experience in the use of a structured interview, the SCID.

Similar training sessions for the second phase of investigators were held in Pisa, Italy, in November 1983.

Data Processing and Data Analysis

This study has generated considerable amounts of data. Data processing is facilitated by the use of upscan forms for primary entry of data. Manual editing is conducted by the Upjohn Company and the data is entered into a computer in Kalamazoo, Michigan. Once the data processing has been completed and an edited tape is prepared, analyses are conducted at two sites — Kalamazoo, Michigan, and Massachusetts General Hospital, Boston, Massachusetts. The primary responsibility of the group at the Upjohn Company in Kalamazoo is the conduct of analyses to ensure proper information for the NDA submission to the FDA for the expected indication of treatment of panic attacks. Analyses primarily for scientific value for research undertaken by the investigators is conducted at the Massachusetts General Hospital under the leadership of Philip Lavori, Ph.D., and myself. Decisions as to scientific publications are made by the principal investigators at their respective steering committees. The Upjohn Company does not assume responsibility for scientific presentation or publication, although it has underwritten a considerable amount of the cost required for statistical analyses, preparation of graphic material, and secretarial assistance.

Conclusions

The findings to be reported here indicate the success of the overall design and the procedures utilized to ensure standardization of diagnosis and maintenance of the protocol across multiple sites in three different countries. It is expected that these procedures and techniques will prove useful in the second-phase study. Inasmuch as the second-phase study involves at least 12 different countries with multiple languages, cultural, and professional traditions, the attention given to diagnostic specification and careful assessment should prove helpful.

Preliminary experience indicates that over the cou[illegible] of the 2 1/2 years since this project was initiated, there have been greater acceptance and diffusion of the concept of panic attacks and panic disorder in relation to agoraphobia, and that participants in this study have increasingly accepted these diagnostic concepts as well as the importance of structured interviews and diagnostic algorithms for the selection of subjects, particularly in an area where there is controversy as to the validity of the diagnostic concept.

A clinical trial such as this one can serve as a partial validation of diagnostic concepts, in this case, panic disorder. The capacity to generate large numbers of cases in multiple sites and to demonstrate consistency of diagnosis and similarity of symptom pattern and of treatment response serves as an indirect validation of the concept of separating panic attacks from other forms of anxiety and linking panic attacks with agoraphobia as a diagnostic complex.

Why a Statistical Package on a Micro?

MaryAnn Hill, Ph.D.[1]

The explosion in microcomputer sales promises to alter our society in fundamental way, changing the way we work, plan, and organize our lives. But without effective software, the microcomputer remains an engaging toy. Many researchers are currently evaluating the role of the micro in their research environment and are asking, "What kind of statistical software do we need?", "Will we have to give up familiar mainframe options?", etc.

There are several advantages in using a microcomputer to do the statistical analysis in research. Locating a micro close to the research team and its original data sheets facilitates data screening and also communication between the technical support staff and the research team. The technical support staff find it easier to focus on the data analysis, because on a micro the interface with the system is more "user-friendly"—allocation and naming of files is greatly simplified and there is no mainframe job control language (JCL). Even if the project is part of a large multicenter trial, much of the data monitoring and screening can be done on the micro and the clean data shipped or networked to the mainframe for final analyses with data from all centers. Finally, most project managers are happy to reduce mainframe computer bills.

Regardless of machine size, it pays to use a statistical package. Advantages include:

- — *Correct computations*. The well-known packages have been "debugged" over a broad range of applications, and they use appropriate algorithms—they do *not* simply code textbook formulas.
- — *More time for research*, because less time is spent programming.
- — It is easier to do *"good" data analysis* because many data screening features appear automatically—e.g., histograms for each group in a two-sample t test.
- — *One-time specification of data description instructions*. Variable names, formats, acceptable range limits, flags for missing data, transformations, etc. do not need to be tailored for each individual analysis.
- — *Documentation and help facilities*. The major package distributors provide extensive manuals, short courses in data analysis, and help via telephone. You are not stuck because your programmer disappears to Tahiti.

— The use of packaged software *facilitates communication of results* when submitting grant proposals and papers to refereed journals, since the methods are well known and documented.

Unfortunately, much of the statistical software for the micro is woefully inadequate. A data analyst needs a wide spectrum of techniques that can be applied easily to a collection of data. If I were called in to consult with your research team, I would need access to a number of features, all of which are currently available on an IBM PC XT or AT (and compatibles). I do not intend to present a detailed explanation of the statistics, but hope to impart a flavor of the breadth of supports required for proper data analysis. From these examples, I hope that you will understand my concern when a research group shows me preliminary results consisting of nothing but means, standard deviations, *F* statistics, and *p* values.

In addition to statistical supports for data analysis, packages often have data manipulation features that merge files and functions that extract information from nonrectangular files. Without such features on a micro, a longitudinal study would be seriously hampered.

Software Features for Data Analysis

Many of the features I would hope to find on your micro are needed for data screening. The term "screening" indicates not only finding errors and inconsistencies in the data, but also ensuring that the data conform to assumptions necessary for subsequent analyses.

FIGURE 2. After weeks of training, why did one doctor's ratings differ? The midpoints of histogram intervals for Hamilton depression scores are printed along the left. Each asterisk represents an observation.

Screening is not one set of procedures carried out prior to the analysis—each stage of the data analysis uncovers information that affects later steps. In sizable studies, the primary analysis of interest may consume 5% of the staff time and computer costs, while data screening takes 95%. The data analyst will want to check for recording errors and compliance to protocol, as well as assess the influ-

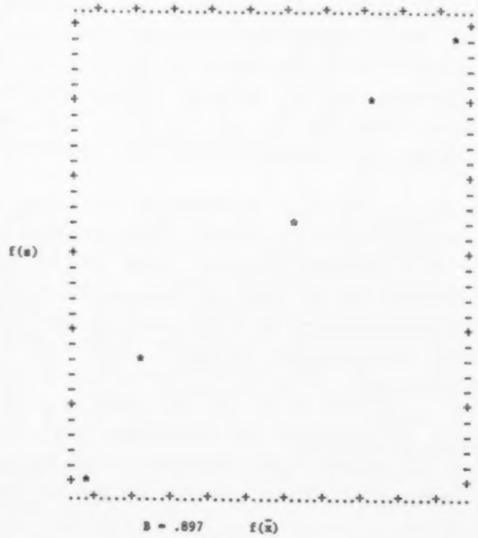

FIGURE 3. Box-Cox diagnostic plot for selecting power transformations to stabilize cell variances in an analysis of variance.

ence of outliers, distributional shape, subpopulations, patterns of missing observations, etc. Having a good statistical package at the research site makes it possible to check the data soon after they are captured—while it may still be possible to make corrections.

Testing group differences

The data analyst needs graphical displays, diagnostics, and alternative tests to help estimate the impact of problems encountered. In comparing responses for a treatment group and a control group, recording errors and other anomalies pop out when you scan small histograms for each group (high resolution graphics are not needed). In Figure 1, case 24, a control subject has a very high response. Does this real, but unusual response change our conclusions about group differences? Compare the results for the usual two-sample *t* test with those for the trimmed *t* test (note the trimmed test does not simply delete the smallest and largest values from each group—an adjustment is made to the standard deviations used in the denominator of the test statistic). Here both tests are significant.

The data analyst wants to study the distribution of values within each cell: scanning a printout of means and standard deviations may be far from adequate. In a recent project, one criterion for study entry was a Hamilton depression score of 18 or above. In a screening run of baseline scores, by doctor, (*see* Figure 2), 6 subjects appear unacceptable for study entry. This was distressing since the admitting psychiatrists had just spent weeks being trained on the anchor points for each individual scale item. So why did one doctor's rating differ? From a quick telephone call we learned that he made his evaluation using the previous 12 hours instead of the patient's history for the past week. Seeing a printout of means would not have had the same impact (the mean for doctor B was over 19).

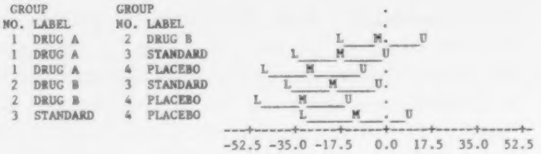

FIGURE 4. 95% confidence intervals for differences in group means with Bonferroni adjustment (means differ significantly when 0.0 is not in the interval).

As structure is added to the design—e.g., we study differences between treated and untreated subjects who are males and females, smokers and nonsmokers, etc.—the data analyst still wants to scan distributions within each cell for outliers and other anomalies. He also needs tests to assess the equality of cell variances, diagnostics to identify the appropriate power transformation, and extensions for the two-sample trimmed *t* test to analysis of variance (ANOVA). In an ANOVA, there should be no relation between the size of the cell standard deviation and the size of the cell mean—i.e., the cell variances should be equal. From information printed with the BOX-COX diagnostic plot (Figure 3), the data analyst would determine that the equal variance assumption is best satisfied if the data are analyzed in log units.

If an effect in an ANOVA is significant, the analysis is still not complete—the researcher wants to report which group means differ from one another. Probabilities from the usual two-sample *t* test cannot be used to find significant differences (since this test assumes that only one pair of means is compared). When many comparisons are made

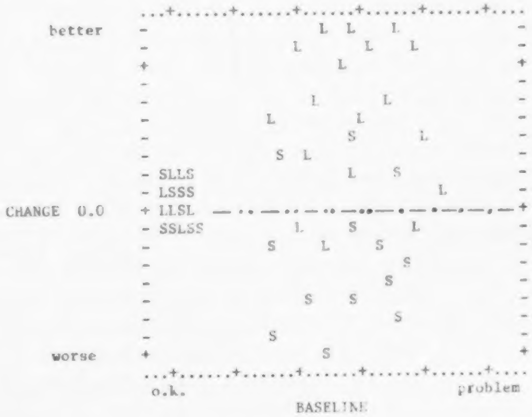

FIGURE 5. A bivariate scatterplot with symbols S and L denoting subjects on DRUG S and DRUG L, respectively, highlights the fact that the CHANGE in cardiovascular status after drug therapy becomes worse for a small subset of DRUG S patients; while several DRUG L patients improved.

simultaneously, the Bonferroni procedure can be used to protect against interpreting too many differences as significant. In Figure 4, confidence intervals (with Bonferroni adjustments) are displayed for differences among four means (DRUG A, DRUG B, STANDARD drug, and PLACEBO)—there is one line in the display for each pair. If zero is not in the interval (draw a vertical line down through the dots to 0.0), the pair has a significant difference in means. The difference between DRUG A and the STANDARD drug is questionable—the upper end of the confidence interval (U) touches the zero line, while the differences between both DRUG A and DRUG B versus PLACEBO are highly significant.

Relating two or more variables

When studying the relation among two or more variables, linear models (e.g., regression models and analyses based on correlations) may not be enough. By scanning a printout of correlations and regression coefficients, the researcher may not be able to see that a small subset of the subjects responds differently from the others. Bivariate scatterplots are useful in such situations, especially when symbols are used to identify subpopulations. In Figure 5, CHANGE in cardiovascular status after drug treatment is plotted against baseline values. Holter monitors were used to obtain the measurements. The majority of the subjects (more than 85% of the sample) exhibited no problems at baseline and no change after being on a drug. However, among those subjects with problems on baseline, several DRUG L subjects improved, while the status of several DRUG S subjects became worse.

Labeling subpopulations in scatterplots is also useful for identifying situations where the presence of subpopulations may mask or falsely enhance the relation between two measures. Two pairs of measures from the Fisher Iris data (Fisher) illustrate this point well. Pooling data for three types of iris flowers into one sample in Figure 6a, masks the relationship between sepal length and width—there is no relationship or at most a slight *negative* correlation. The points labeled "S" in the lower right are Setosa flowers—note how the relation for them appears to be *positive* (for the Setosa flowers alone, the correlation is +.74). In Figure 6b, when data are pooled for a plot of petal length versus width the correlation is .96; for Setosa alone, the correlation drops to .33.

When studying the intercorrelations of many variables—e.g., in the development of a questionnaire or a rating instrument—it is helpful to use a factor analysis to sort the rows and columns of a correlation matrix into blocks of similar values, and then to use a single character space to represent each correlation (*see* Figure 7, for a shaded correlation matrix for a 43-item questionnaire about smoking habits and emotional stress). The 13 smoking items appear highly intercorrelated, with the possible exception of the last item in the list, SMOKING 3. The question about

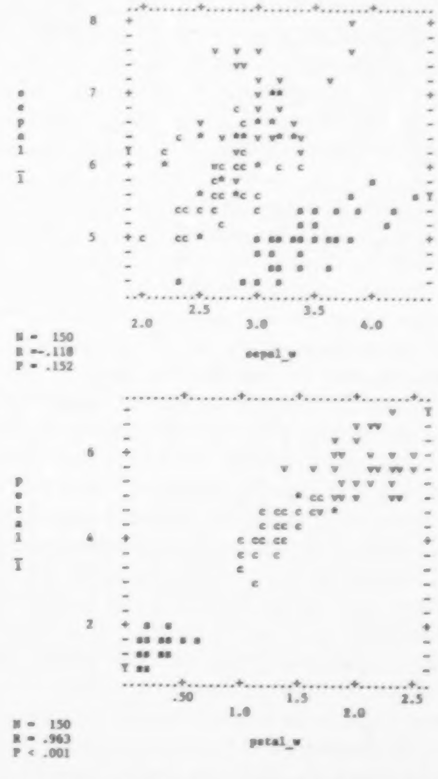

FIGURE 6. **a) The presence of subpopulations can mask a relationship: sepal length versus sepal width. b) For petal length and width, the presence of subpopulations gives a false impression of the strength of the relationship.**

hunger (HUNGRY—the third up from the bottom of the display) appears to have little relation to any of the other items.

When there are only two variables of interest, much can be gleaned from studying a scatterplot. However, as the number of variables in a multivariate analysis increases, additional diagnostics are needed to identify outliers and cases that exert unusual influence on the analysis. In the plot of Andrews-Pregibon statistics in Figure 8, unusual values of the statistic plotted on the AP1 axis indicate outliers in the dependent variable. One value at the top right stands apart from the others and should be checked. Unusual values on the AP2 axis are "leverage" points—cases that exert the greatest influence on the regression coefficients. Here two cases are separated from the others and identified as

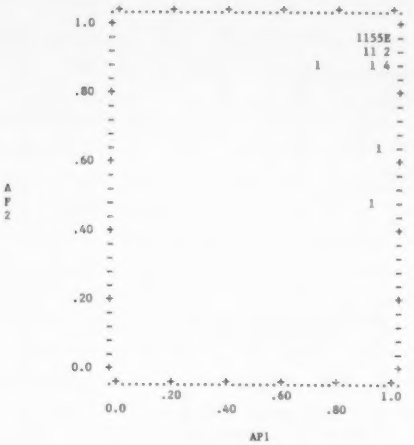

FIGURE 8. Andrews-Pregibon diagnostics AP1 and AP2 for identifying outliers and leverage points in multiple regression.

unusual. The case numbers for the three cases identified are printed in the output.

Studying the pattern of incomplete data

Missing data are often a nightmare for the data analyst. Procedures for dealing with incomplete data usually assume that values are missing randomly. The pattern of how values are missing should be investigated, since non-randomly incomplete data can bias results. One of the first things the data analyst does when searching for patterns is to print a display of the data with one character per variable: a blank if an observation is present: a letter "M" if missing. In Figure 9, the LAB chemistry measures tend to be missing as a set. In Figure 10, a multiway table is used for deciding if this pattern is related to the outcome, SURVIVAL. Over two-thirds of the survivors (68.5%) are missing all three lab values, while fewer than 10% of the non-survivors have data missing.

FIGURE 10. Column percents in a multiway table for assessing the relation between SURVIVAL and the pattern of incomplete data for three lab chemistries.

Software Features for Managing the Data

Data in longitudinal studies often fail to conform to the nice tidy rectangle required for analyses based on classical statistics. Patients may have varying numbers of visits and different patterns of return across time. For example, it may be necessary to extract from a series of records the number of visits, total time on study, percent improvement for the clinical rating score, worst side effect score, drug dose for week prior to worst score, etc., for each patient. For analysis, the summary of the patient's clinical experience will need to be merged with laboratory results and patient history data.

The entry of patients into the study may be staggered over time, making it hard to visualize the pattern of return visits and the total time on study for members within each treatment group. In order to plan analyses, the data analyst needs this information. In Figure 11, a record map is displayed for a study where patients are asked to return weekly for evaluation (one computer record is generated for each return visit). Week-on-study is recorded on the horizontal axis, and each row represents the pattern of returns for a single patient over time. The drug code is used as a

FIGURE 11. Record map for clinical trial with weekly outpatient visits.

plot symbol; blanks mark missed visits. Subject 19 (*see* underlined row) was randomly assigned to drug 1 (the plot character is 1) and continued on it for 17 weeks; had 2 weeks of wash-out (code 4); and then was randomized to drug 2. It is immediately apparent that, as time on study increases, many patients drop out and the frequency of returns decreases.

With such a distribution of values across time it is hard to use a classic repeated measures design to test for differences among the drug groups. Instead, our strategy might be to extract information from each patient's set of records (the number of records varies by patient). This summary information would then form a rectangular file and be available for plots, histograms, analysis of variance, logistic regression, etc. The data for each patient might include clinical ratings (at baseline, 4 weeks, 8 weeks, and so on.), proportion of visits with side effects present, maximum dose, drug dose for week prior to worst side effects score, and within-subject correlation between dose and side effects.

Conclusion

A microcomputer can be an effective tool for data analysis, but only if adequate software is available. A statistical package for a micro must go far beyond the simple computations of commonly used statistics. Indeed, it must encompass most of the power of the standard mainframe packages.

Microcomputerized Testing of Drug Effects on Divided Attention[1]

Joe E. Thornton, M.D.,[2] Joy L. Taylor, Ph.D.,[2] Elizabeth L. Gibson, M.A.,[2] Terry P. Miller, M.D.,[2] and Jared R. Tinklenberg, M.D.[2]

In this paper we describe the use of a microcomputerized, dual-task methodology to test drug effects on divided attention. This dual-task methodology is designed to be sensitive to psychoactive drugs and to be useful in research that entails repeated assessments of the same individual. The theoretical rationale for this approach is that drug effects may be especially discernible on pervasive, non-specific processes such as attention and may be most amenable to quantification on performance tasks that are attention demanding. Certain additional psychometric and technical features of these microcomputerized tasks which make them suitable for psychopharmacologic studies will also be discussed.

Methods

The essential feature of the dual-task method is that the subject must perform two activities simultaneously. In one version of this method, which is described below, the subject also performs each task individually to provide comparisons for the dual-task condition. The decrement in performance observed when the two tasks are done simultaneously, relative to the performance observed when they are done separately, provides a measure of the extent to which the available attentional capacity is exceeded.

In our basic dual-task procedure, the first task involves manipulating an x-y joystick to pursuit track a randomly moving target, which is displayed on a video screen. The subject manipulates this control stick up/right and left/right with the preferred hand. The target is a 1.5 cm horizontal line and the joystick position is displayed as a 1.5 cm vertical cursor line. The task is to maintain a "crosshair" configuration by keeping the middle of the vertical cursor line as close as possible to the middle of the randomly moving horizontal target line. The target moves at a maximal rate of about 6.6 cm/sec throughout an unmarked 12 × 18 cm rectangle, positioned at the center of a standard 42 cm diagonal video screen. The screen is approximately 50 cm from the subject's eyes.

The second task involves the continuous monitoring of visual probe stimuli embedded in the horizontal tracking target line. The stimuli are a pair of boxes, about 4 mm long × 5 mm high, at each end of the target line. They both blink in synchrony at a baseline rate of about 1 blink/sec. The subject presses the reaction button, which is held in the non-preferred hand, as soon as he or she notices an increase in blink frequency of the boxes (to 1.8 blinks/sec). This change occurs at quasi-random intervals, approximately 4 times per minute. The button press restores the blink frequency to baseline. The temporal perceptions required in this task and the relatively high rate at which the visual stimuli must be processed combine to enhance drug sensitivity. Both tasks are designed to be intrinsically uninteresting and subtle in their measurement of performance changes. Most subjects perceive these tasks as undemanding commercial videogames, which are meant to arouse and stimulate.

The basic procedure involves three test conditions: a) a single-task only is performed, the other is ignored; b) the other single-task only is performed, the first is ignored; and c) then both tasks are performed concurrently. In the dual-task condition the subjects are

instructed to do the tracking task as well as possible and do the visual probe monitoring with whatever abilities remain. In experiments where we focus on attentional capacity, each task condition lasts 5 minutes. The order of tasks is first tracking only, then reaction task only, and then both tasks simultaneously (dual-task). Any decrement in the dual-task condition relative to the single task conditions indicates the extent to which the available attentional capacity is exceeded. In experiments where we are most interested in drug effects on general performance, we use only the dual-task condition and measure time-on-task changes during 15 or 20 minutes of continuous performance. Continuous performance obviates the confounding effects of any task interruption. The subjects receive no feedback about their performance in either paradigm.

We use Apple II and Apple IIe hardware with programming done in UCSD-Pascal. The tasks are run on an Apple II (or IIe) microcomputer using the UCSD Pascal Operating System. It requires a) an x-y joystick; b) a California Computer Systems programmable timer module (PTM) card, appropriately modified, in slot seven of the Apple II; c) a press button switch connected to the PTM; and d) dual floppy disk drives for data storage. The software for the pursuit tracking and visual monitoring procedure (PTRAK), described above, is written in UCSD Pascal and 6502 machine code. The Pascal portion of PTRAK controls the presentation of the secondary visual probe and records performance; the 6502 routine draws the positions of the target and cursor. Every 75 msec tracking accuracy is measured as the radial distance in pixels between target and control stick cursor. A pixel in this system is about a 1.0 mm horizontal and 0.6 mm vertical dot. Reaction time to the probe (to 1 msec accuracy) or a "miss" (i.e., no response within 1500 msec) are recorded. Additional technical and theoretical considerations are described elsewhere (Tinklenberg & Taylor, 1984; Tinklenberg et al., 1984, 1985).

Results

In repeated measures research designs such as those usually used in clinical psychopharmacology, an essential requirement for any performance assessment procedure is adequate test-retest reliability. We determined the test-retest reliability of PTRAK on five normal volunteers in the basic divided attention paradigm. When testing was done 1 day apart the Pearson correlation coefficients were greater than 0.80 on both tracking and reaction time performance. Testing after 1 week, the Pearson coefficients were greater than 0.69 for both tasks. One subject was tested 20 times over a 6-month period. Examination of his performance indicates an immediate improvement or practice effect in the 5-minute paradigms if testing is done on the same day or on consecutive days. This practice effect is not evident if testing sessions are more than a week apart. When the subject was tested for 10 consecutive days, performance stabilized by the fifth testing day. In the 20-minute time-on-task paradigm, practice effects are less evident.

Another obvious requirement for any psychopharmacological assessment procedure is appropriate drug sensitivity. Initial studies with dual-task procedures are promising. In a single-blind study with normal subjects, single doses of diphenhydramine 50 mg orally significantly impaired performance; 100 mg of caffeine 3 hours after diphenhydramine ingestion restored most of the performance deficit. When diphenhydramine followed caffeine, performance did not improve. We have also shown PTRAK to be sensitive to drug effects in abstinent alcoholics (Miller et al., in press). There was consistent impairment of dual-task performance with diphenhydramine: 50 mg, diazepam: 10 mg and 20 mg, and secobarbital: 100 mg.

Discussion

These preliminary results suggest to us that microcomputerized dual-tasks have adequate reliability and drug sensitivity for use in research. They also have many practical advantages in psychopharmacological studies relative to traditional tasks. Patient acceptance is generally good, and they often enjoy the game-like quality of the task. Since specific feedback is not given and level of performance is not apparent, performance anxiety is minimized. Also, the equipment is portable, relatively inexpensive, and can be adapted to obtain concurrent physiological measures of arousal such as heart rate. Personnel requirements are minimal. A tester requires little training and once the task instructions are given to the subject, the tester does not have to be present. The testing conditions are standardized and exactly replicable, even among different research groups. This is especially important with the repeated measures designs often required in testing for effects of drugs on cognitive performance.

There are also psychometric characteristics of these dual-task procedures that make them attractive for pharmacological studies. A common problem in psychopharmacology is the wide range in the performance abilities of patients. Tests that are too easy for some subjects are too difficult for others. With dual tasks these "ceiling" and "floor" restrictions are circumvented to some degree. The tracking task can be performed at widely varying levels of proficiency—ranging from continuous close contact with the target to distances on the order of 4 to 5 cm—and still be statistically and psychometrically meaningful. This feature of the tracking task is in contrast to our experience with, for example, verbal learning tasks. A second psychometric advantage is the tests' suitability for repeated assessments. Unlike some standard intelligence and memory tests, which have only a single form of the test, each session of this computerized performance test consists of randomized presentation of stimuli.

There are more potential advantages with microcomputerized dual tasks. Adaptive logic can be used so that task difficulty varies during a single test session, e.g., the performance of subjects with different abilities can be kept within specified error limits. The priority assigned to each task can be systematically manipulated so additional inferences can be made about attentional capacitites and control. Dual-task results can be interpreted on the basis of extensive theoretical and experimental work in human factors research.

There are some problems with the microcomputerized testing. Our experience indicates the need for experimental designs which can control for practice effects and performance variability due to factors such as time of day, smoking, diet, exercise, emotional state, etc. Also, some subjects change performance strategies, so that testers occasionally have to monitor the subjects performance throughout a session. With the procedure described above there is a lack of face validity, i.e., a more meaningful task might require the same perceptual and motor skills but use a graphics and hardware system that resembles an automobile. But even at this simple level the technical demands of initial development and modification are formidable and require professional engineers and computer programmers.

In summary, we believe the special psychometric characteristics and sensitivity to experimental interventions make microcomputerized dual tasks a potentially important tool in clinical psychopharmacology.

The Use of Benzodiazepines for Psychotic Disorders: A Literature Review and Preliminary Clinical Findings[1]

George W. Arana, M.D.,[2] Marjorie L. Ornsteen,[2] Fred Kanter, M.D.,[2] H. L. Friedman, M.D.,[2] David J. Greenblatt, M.D.,[2] and Richard I. Shader, M.D.[2]

Introduction

Although antipsychotic agents (neuroleptics) have been shown to be effective for the treatment of various psychotic disorders including schizophrenia and the affective psychoses, limiting factors such as latency for onset of action (10 to 14 days) and short- (acute dystonias, neuroleptic malignant syndrome), medium- (parkinsonism, akathisia), and long-term side effects (tardive dyskinesia [TD]) have necessitated the search for other compounds that may be effective for psychotic symptoms (Baldessarini, 1980). Recent findings suggest that certain subgroups of psychotic patients may be at increased risk for TD depending on age, diagnosis, and duration of treatment (Mukherjee et al., 1982; Toenniessen et al., 1985), although much controversy still exists about these associations (Kane & Smith, 1982). Benzodiazepines, because of their low toxicity, have been studied both as potential non-neuroleptic antipsychotic agents and as adjunctive treatments for psychotic disorders, to increase sedation and possibly to allow for a significant reduction of neuroleptic dose.

We will review briefly the available literature on the use of benzodiazepines for psychotic disorders, present data from a retrospective chart review on the utility of combined use of neuroleptics and lorazepam, and review preliminary findings of an ongoing study assessing the use of lorazepam alone and lorazepam combined with haloperidol in two groups of psychotic inpatients.

In the literature review we included only those publications containing the actual number of patients responding to a specific regimen. This allowed us to construct efficacy and toxicity data about those who either responded or developed toxicity as a function of the total number treated across studies. Because the efficacy criteria were not uniform among the individual publications, it was not possible to clearly specify whether improvement was in core psychotic symptoms or in such associated symptoms as anxiety and agitation.

Efficacy of Benzodiazepines for Psychotic Illnesses

Diazepam

Although a variety of benzodiazepines have been employed in the treatment of psychotic disorders, diazepam is the most frequently studied compound. Table 1 presents the selected literature on the use of diazepam for schizophrenic disorders (Beckman & Haas, 1980; Hollister et al., 1963; Jimerson et al., 1982; Jos et al., 1985; Maculans, 1964; Nestoros et al., 1982, 1983; Ruskin et al., 1979; Weizman et al., 1984).

Early uncontrolled studies using relatively lower doses of diazepam were conflicting, some reporting dramatic reductions in hallucinations mand delusions in schizophrenics (Irvine & Schaechter, 1969; Kramer, 1967; Sussex et al., 1961) and others reporting that diazepam had little effect. As is evident from Table 1, few patients were studied in well-controlled clinical trials with fixed-dose regimens.

When double-blind trials are assessed separately, only 14 of 47 subjects (29%) were found to have responded, an efficacy rate equal to what is generally regarded as placebo response rate. Factors which could contribute to response rate such as clinical presentation, response to other medications, or the utility of combined therapies are inconsistent when reviewing this literature. One double-blind study described the use of diazepam for schizophrenic patients who previously were poor neuroleptic responders (Maculans, 1964); another reported a response rate to diazepam comparable to the neuroleptic response rate (Jimerson et al., 1982). Two groups, in double-blind crossover studies using diazepam, found no antipsychotic effect as compared with placebo in doses from 40 to 80 mg/day in one (Ruskin et al., 1979) and 300 mg/day in the other (Jimerson et al., 1982). In contrast to these negative findings, another group reported a dramatic reduction in both positive and negative psychotic symptoms, a broad range of diazepam doses were employed (70 to 400 mg/day) (Nestoros et al., 1982). Finally, in a double-blind randomized trial of haloperidol and diazepam (not shown in Table 2), both compounds were equally effective for the treatment of psychotic symptoms in the first 24 hours, with a trend in favor of diazepam in the first 4 hours (Lerner et al., 1979). The authors speculate that some components of psychosis may be secondary to arousal or anxiety, thus leading to the apparent efficacy of a benzodiazepine compound for psychotic symptoms (Lerner et al., 1979).

#(Patients with antipsychotic response)/(Total patients studied).

**Patients concomitantly treated with haloperidol, 15 mg/day.

When all cases (double-blind and others; Table 1) are totalled, response rate is 34% (42/120). The studies reporting the use of diazepam at doses below 40 mg ($N = 60$; 51%) yielded a response rate of 28% (17/60); the three reports using over 100 mg of diazepam had an overall response rate of 33% (11/34). There does not appear to be a dose-related response pattern for diazepam in psychotic illnesses. An overall response rate of approximately 30% emerges regardless of dose used or the design of the studies.

In addition to diazepam, other benzodiazepines have been used for the treatment of psychosis (*see* Table 2). Although these reports are brief and preliminary, they offer some data on the efficacy of this class of drugs for psychotic and bipolar disorders (Astrup & Vatten, 1984; Chouinard et al., 1983; Csernansky et al., 1984; Deberdt et al., 1973; Freinhar & Alvarez, 1985; Guz et al., 1972; Hekimian & Friedhoff, 1967; Holden et al., 1968; Karson et al., 1982; Kellner et al., 1975; Lingjaerde, 1982; Modell et al., 1985; Monroe & Wise, 1965; Victor et al., 1984).

Clonazepam

Recently, interest has developed in the use of clonazepam, a benzodiazepine usually employed for its anticonvulsant properties (Browne, 1976). A number of papers have appeared exploring its value for the treatment of psychotic illnesses, particularly mania (*see* Table 2). Unlike neuroleptics, there is little risk of extrapyramidal or anticholinergic side effects, although drowsiness and ataxia, apparently dose-related symptoms occurring early in treatment, appear to be problematic (Browne, 1976).

Few controlled clinical trials of clonazepam have been conducted to assess its efficacy in the treatment of mania and psychosis. In a double-blind crossover study of 12 acutely manic patients, one group has reported that clonazepam was as effective as lithium for manic symptoms and superior to lithium for motor activity and logarrhea (excessive speech) (Chouinard et al., 1983). Two reports describing 5 patients found that clonazepam ameliorated anxiety and agitation and a limited number of manic symptoms, but psychotic symptoms (delusions, hallucinations) were refractory (Freinhar & Alvarez, 1985; Victor et al., 1984). Two reports suggest that clonazepam may precipitate aggressiveness and irritability (Browne, 1976; Karson et al., 1982). One group, in a double-blind study of 9 schizophrenic patients concomitantly treated with neuroleptics, found clonazepam to be ineffective for target symptoms of psychosis. In addition, 4 patients developed aggressive, violent outbursts, 3 of whom had no prior history of violence. The assaultive episodes occurred when the dose was being adjusted (Karson et al., 1982). These investigators concluded that clonazepam was not effective in the treatment of exacerbations of psychosis in chronic schizophrenics receiving neuro-

[b] Patients treated concomitantly with lithium.

leptics, and that it had the potential for inducing aggressive behavior. Finally, another report has indicated that psychotic symptoms, including irritability and aggression, may worsen in adolescents treated with clonazepam (Browne, 1976).

Lorazepam

Lorazepam is well established in psychiatry as an anxiolytic. Its efficacy in psychotic disorders is less well studied and confounded by secondary anxiety and arousal that may coexist in many psychotic patients. One investigator suggests that lorazepam is an effective adjuvant for the anxiety which accompanies psychosis but has no effect on the target symptoms of psychosis (Deberdt, 1973). A recent open clinical trial found lorazepam effective in the control of manic agitation and in promoting compliance and cooperation during the institution of lithium therapy, concluding that manic as well as other psychotic symptoms resolved within 10 days when both lithium and lorazepam were used (Modell et al., 1985). However, the course of recovery from the manic episode left it unclear as to which drug was more effective (Modell et al., 1985).

Estazolam

The effects of estazolam, a benzodiazepine not currently marketed in the United States, have been tested in psychotic illnesses. In a double-blind study of estazolam in 58 chronic schizophrenics, it was found that estazolam in combination with a neuroleptic was better than neuroleptic alone for the treatment of hallucinations and compulsive thoughts as evident in global clinical improvement (Lingjaerde, 1982). Another group reported the use of 4 to 6 mg of estazolam in an open trial for 53 chronic schizophrenics, concluding that this drug decreased delusional and paranoid symptoms in 15/53 patients (Astrup & Vatten, 1984). In both studies, patients were characterized as poor neuroleptic responders and were maintained on neuroleptics during the treatment with estazolam. Although encouraging, further placebo-controlled studies are needed to assess the specific efficacy of estazolam in these patients.

Alprazolam

In an open trial of alprazolam evaluating its therapeutic effect on the negative symptoms in 8 chronic schizophrenics, partial reversal of negative symptoms was observed in 6 patients, and an anxiolytic effect in all 8. (Csernansky et al., 1984). Conclusions that can be drawn from this particular study are limited, as all patients were concomitantly treated with neuroleptics. Fifty percent of the patients had a moderate overall clinical response to alprazolam. Because alprazolam is known to be effective for anxiety, panic, and depressive disorders, this improvement may have been secondary to other possible effects of this drug.

Chlordiazepoxide

Seven reports on the use of chlordiazepoxide reveal generally inconsistent findings on its efficacy in psychosis. In particular, the question of increased efficacy for psychosis if both chlordiazepoxide and neuroleptics are employed is unanswered. Three studies between 1966 and 1970 compared the combination of an antipsychotic and chlordiazepoxide with an antipsychotic alone in newly hospitalized acutely psychotic patients at Spring Grove State Hospital in Maryland and found that the combination drug treatment was less effective than the antipsychotic alone (Hanlon et al., 1969, 1970: Michaux et al., 1966). In an open trial comparing chlorpromazine, chlordiazepoxide, and placebo in 30 schizophrenic patients, 4/10 treated with chlordiazepoxide alone improved with regard to psychotic symptoms: also, chlordiazepoxide in combination with an antipsychotic was more effective than the antipsychotic alone in regard to thought disorder and motor behavior (Hekimian & Friedhoff, 1967). Consistent with these observations is a report showing that the addition of chlordiazepoxide to an antipsychotic regimen was effective in controlling acutely psychotic, episodically dyscontrolled patients (Monroe & Wise, 1965). Another group of investigators reported that chlordiazepoxide was not effective in the treatment of psychosis and that most changes in global ratings were due to the sedative and calming effects of chlordiazepoxide (Holden et al., 1968). Finally, a report on 6 schizophrenic patients concomitantly treated with neuroleptics found that 3/6 patients demonstrated an adequate response. Overall, the response rate with chlordiazepoxide in psychotic illnesses among 75 patients is just over 50%, but over half of these patients also were treated with neuroleptics. Therefore, conclusions regarding efficacy of chlordiazepoxide alone must be tentative.

Benzodiazepine Toxicity in Psychotic Illnesses

A review of seven publications (Beckman & Haas, 1980; Haas et al., 1982; Hollister et al., 1963; Jimerson et al., 1982; Karson et al., 1982; Lerner et al., 1979; Maculans, 1964) revealed a variety of side effects reported with both diazepam and clonazepam in a total of 114 patients (Table 3). Except for the final study cited which reported on manic patients (Chouinard et al., 1983), all patients were reportedly schizophrenic. However, the diagnostic criteria employed varied and many of these may have fallen in the affective spectrum if DSM-III (Diagnostic and Statistical Manual—3rd ed., 1980) were being used. In this group of patients, it was evident that the two general types of side effects seen in these reports included sedation/quieting and arousal/stimulation. This preliminary literature review would suggest that certain benzodiazepines may have a significant likelihood of producing sedation or stimulation in certain psychotic patients. The particular pattern of behavioral toxicity in an individual may be idiosyncratic, or may be mediated via other poorly understood factors not readily apparent in the limited sample reviewed.

It is of note that the arousal/stimulation pattern of toxicity seen in a number of schizophrenic patients is reminiscent of manic symptoms, i.e., hypersexuality, hyperkinesis, excitation, euphoria, and impulsive behavior. This would suggest that caution must be exercised in interpreting these symptoms in diagnostically complicated cases who are treated with benzodiazepines during the clinical evaluation period. This arousal pattern seen with the use of certain benzodiazepines in chronically psychotic individuals may confound the diagnostic process, as is mentioned in the Discussion section.

Preliminary Clinical Results With the Use of Lorazepam in Psychotic Illnesses

Retrospective Chart Review of Patients Treated With Neuroleptics and Lorazepam Over a 6-Month Period

Between January 1984 and July 1984 a total of 380 patients were admitted to one of three 22-bed acute inpatient units in the Department of Psychiatry at the Boston Veterans Administration Medical Center. When clinically indicated, patients were treated

TABLE 3

Toxicity Reported With Benzodiazepines in Psychotic Disorders

Author	Year	Benzodiazepine	Toxicity Rate	Description
Hollister et al.	1963	Diazepam	9/25	"Worsening of psychosis
Maculans	1964	Diazepam	7/35	Sedation
Beckman and Haas	1980	Diazepam	5/15	Hypersexuality; hyperkinesis; excitation.
Haas et al.	1982	Diazepam	4/8	Euphoria; hyperkinesis.
Jimerson et al.	1982	Diazepam	3/6	Ataxia; sedation
Karson et al.	1982	Clonazepam	3/13	Violent behavior
Chouinard et al.	1983	Clonazepam	7/12	Sedation
Totals	Sedation		17/53 (32%)	
	Arousal/Stimulation		21/61 (34%)	

NOTE: All patients were diagnosed as schizophrenic except in the Chouinard study in which patients were diagnosed as bipolar disorder, manic type.

TABLE 4

Neuroleptic Dose Requirements in Psychotic Disorders: Neuroleptics With and Without Lorazepam (LZP)

Treatments	*N* (Total = 30)	CPZ-EQ (mg)* (mean ± SEM)
A Neuroleptics	22	560 ± 85
B Neuroleptics + LPZ [a]	8	265 ± 50

*Chlorpromazine-equivalents/24 hrs./patient: doses were at discharge and were determined to be lowest dose for effective control of psychotic target symptoms.
[a] Mean lorazepam dose = 2.75 mg/24 hrs.
Statistical Data:
B vs. A: $t = 2.99$; $df = 28$; $p < .01$

with doctor's choice of neuroleptic, doses being tapered continuously during hospitalization to achieve the lowest effective dose. Of the 380 admissions, it was found that 30 patients were discharged with either neuroleptic or neuroleptic with lorazepam at the lowest doses clinically possible without an exacerbation of symptoms. Mean discharge dose of neuroleptic was comparable for the three units as was average length-of-stay. Patients with a significant degree of agitation initially were treated with lorazepam and were discharged with the lowest effective dose of this compound.

Table 4 presents the neuroleptic dosages employed, converted to chlorpromazine-equivalents (CPZ-EQ) (Baldessarini, 1980), on these 30 patients separated into treatment groups: 1) neuroleptics, and 2) neuroleptics with lorazepam. In 22 patients discharged on neuroleptics alone, mean CPZ-EQ/day was 560 mg whereas in 8 patients treated with both neuroleptics and lorazepam (mean lorazepam dose = 2.75 mg/day), the mean CPZ-EQ/day on discharge was 265 mg, a difference found to be statistically significant ($t = 2.99$; $df = 28$; $p < .01$). Data on 32 patients not shown were separated into two other treatment subgroups: 1) neuroleptics and benztropines, and 2) neuroleptics, lorazepam, and benztropine. The group of patients treated with both neuroleptics and benztropines ($N = 18$; mean dose benztropine = 2.2 mg) had a mean CPZ-EQ dose of 771 mg/day (SEM ± 164). The group of 14 patients treated with neuroleptics, lorazepam, and benztropine had a mean CPZ-EQ dose of 933 mg (SEM ± 227) (*see* Table 4).

Although patients were tapered to lowest effective dose for treatment of psychotic symptoms, the heterogeneity of the population made it difficult to separate dose requirement of neuroleptic from severity of illness. Because lorazepam was initiated for agitation and irritability, it is unlikely that this cohort represented less severe forms of psychosis although, without controlling for severity, this assumption remains untested. The dose of neuroleptics in the group receiving concomitant lorazepam therapy was clearly lower than the other group shown. This lower dose of neuroleptics also may have led to a lower incidence of extrapyramidal side effects and/or akathisia, therefore not requiring the use of benztropine. This reduced requirement for neuroleptics may have reduced the incidence of neuroleptic-induced toxicity which may have reflected itself as an overall improved clinical picture at relatively lower doses of antipsychotics. Further research with carefully controlled groups of psychotic patients with uniform symptom profiles on fixed doses of neuroleptics is needed to assess whether there is a significant interaction between these two medications which allows for use of lower doses of neuroleptics. Also, it remains to be assessed whether the reduced neuroleptic dose lowered the incidence of neuroleptic-induced side effects, i.e., akathisia, hence leading to apparent efficacy which, in fact, was reduced toxicity.

Preliminary Results of the Efficacy and Toxicity of Lorazepam in 14 Psychotic Patients

Preliminary results from an ongoing study on the efficacy of lorazepam vs. lorazepam with haloperidol for psychotic disorders were reviewed. Acutely psychotic patients between the ages of 18 and 65 were admitted to a research inpatient service at the Boston Veterans Administration Medical Center, underwent a complete battery of clinical and laboratory tests to exclude active medical conditions, and were stabilized with regard to diet and fluid intake. Subjects able and willing to sign informed consent were observed clinically for 48 hours following admission and rated daily with the Brief Psychiatric Rating Scale (BPRS) to determine the nature and intensity of psychotic symptoms. Those patients who demonstrated a clear improvement in psychotic symptomatology in this time period were excluded from study and the remaining patients were treated either with lorazepam or lorazepam with haloperidol. Blood samples for analysis of lorazepam and haloperidol were drawn into heparin-containing tubes, centrifuged, separated, and kept frozen at −20° C until assay. Lorazepam was measured by gas liquid chromatography with electron-capture detection (Greenblatt et al., 1978); haloperidol was measured by gas liquid chromatography with a nitrogen-phosphorus detector (Abernethy et al., 1984).

Table 5 presents data on the 14 patients studied including basic demographics, diagnostic data, doses of lorazepam and haloperidol employed, and specific items on the BPRS showing significant improvement over the 48-hour period of treatment. Diagnostic evaluations were performed by a research psychiatrist and a research assistant employing DSM-III criteria with the aid of the Structured Clinical Interview for DSM-III (SCID). Eight patients with diagnoses of mania ($N = 4$), schizophrenia ($N = 3$), and atypical psychosis ($N = 1$) were treated with a mean dose of 20.9 mg/day of lorazepam alone and demonstrated a mean drop in BPRS scores of 20; BPRS items showing significant improvement ($p < .05$) were tension, hostility, suspiciousness, hallucinations, unusual thoughts, conceptual disorganization, excitement, and emotional withdrawal. Six patients divided equally between mania, schizophrenia, and atypical psychosis were treated with both lorazepam and haloperidol. The mean lorazepam dose was 16.5 mg/day and mean haloperidol dose was 14.2 mg/day. The items on the BPRS which showed significant improvement were grandiosity, unusual thoughts, conceptual disorganization, blunted affect, and emotional withdrawal ($p < .05$).

In order to assess the differences between high-dose (>30 mg/day; $N = 3$) vs. low-dose (<10 mg/day; $N = 5$) lorazepam among the lorazepam-treated group ($N = 8$), and to assess the differences between low-dose lorazepam ($N = 5$) vs. low-dose lorazepam with low-dose haloperidol ($N = 4$), clinical response data were analyzed in this same cohort of patients (*see* Table 6; N.B. Two patients treated with lorazepam and haloperidol who were included in Table 5 were treated with >20 mg/

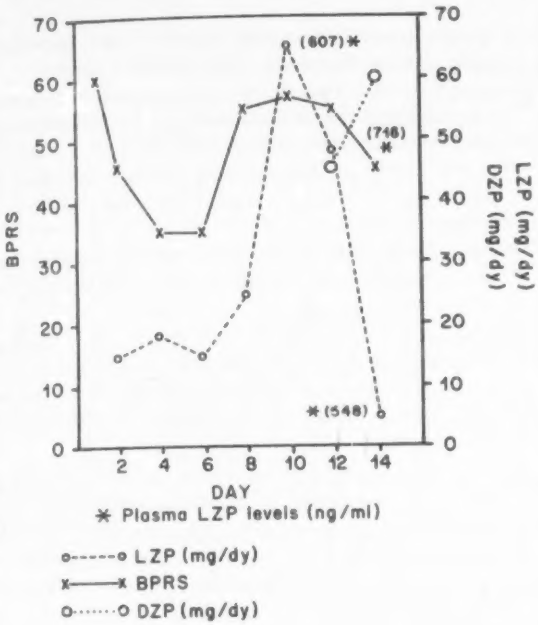
day of lorazepam and were not included in the data analysis in Table 6). Mean daily lorazepam dose in the high-dose lorazepam group was 45 mg with a mean plasma level of 688 ng/ml. Nonpsychotic symptoms that were significantly improved included tension, hostility, and excitement; psychotic symptoms showing improvement were suspiciousness and conceptual disorganization. In the group receiving high-dose lorazepam, significant worsening in motor retardation and blunted affect was noted. The low-dose lorazepam group ($N=5$) received a mean daily dose of 6.2 mg/day with mean plasma levels of 29.5 ng/ml. Clinical improvement was noted with excitement, unusual thoughts, and emotional withdrawal. The 4 patients treated with both lorazepam and haloperidol were treated with mean doses of 5 mg/day and 15 mg/day, respectively. Improvement was noted in conceptual disorganization, unusual thoughts, and emotional withdrawal.

Time Course of Treatment Response of a Manic Patient

The Figure (p. 85) outlines the 2-week course of a 42-year-old white male, bipolar manic patient treated only with lorazepam and diazepam over a 14-day period. Presenting symptoms on admission included paranoia, grandiosity, insomnia, loss of appetite, restlessness, agitation, labile affect, pressured speech, racing thoughts, and poor judgment. The total BPRS score on admission was 60. By history, this episode began 4 months prior to admission.

The patient was begun on 8 mg oral lorazepam daily with 2 mg doses administered as needed for agitation. A BPRS to assess severity of psychosis and response to treatment was completed daily by a research psychiatrist. Within the first 24 hours of treatment, he received 15 mg of lorazepam and showed moderate improvement in symptoms such as



uncooperativeness, excitement, and suspiciousness as defined by a 2-point decrease on BPRS subscales. After 48 hours of treatment, total BPRS score had dropped to 33. There continued to be marked improvement in grandiosity, tension, unusual thought content, and conceptual disorganization through day 6. Unexpectedly, between day 6 and day 8, with little change in daily lorazepam dose (between 16 to 24 mg) he demonstrated a clear worsening in his clinical state as reflected in increasing BPRS scores with manic symptoms similar to those evident on admission (*see* Figure). The lorazepam dose was increased to 65 mg daily with a plasma lorazepam level of 607 ng/ml with no improvement in psychotic symptoms. Because of his failure to respond, lorazepam was rapidly tapered and on day 12, diazepam was started in order to avoid possible withdrawal symptoms from the high-dose lorazepam regimen. On day 15, haloperidol treatment was initiated with marked improvement in 3 days and remission in 2 weeks.

This case characterizes the time course observed with other psychotic patients treated with lorazepam in whom rapid improvement is not sustained beyond 4 to 6 days, with little benefit attained by increasing lorazepam dosage. This was evaluated with lorazepam levels which confirmed that drug levels increased with increasing dosage. Because antipsychotic effect was not attained with increased levels of lorazepam, this would not suggest that tolerance was developing to the antipsychotic effect of lorazepam. Further clinical and preclinical work is needed to better understand this pattern of clinical effect in psychotic illnesses.

Discussion

It is evident from this literature review that benzodiazepines are not as effective in the treatment of psychotic disorders as neuroleptics or lithium salts. The efficacy rate of benzodiazepines for the treatment of psychosis, usually reported as schizophrenia (not necessarily DSM-III), is approximately what would generally be expected from placebo rates of response (Tables 1 and 2; 98/278 = 35.2%). Because many of these reports were retrospective and/or included patients concomitantly treated with neuroleptics or lithium, the actual response rate may be lower than the apparent 35.2%.

Toxicity seen when psychotic disorders were treated with benzodiazepines included the expected sedation and drowsiness characteristic of this class of medication (32%), but also included arousal and excitation (34%) manifesting as manic symptoms in some cases and, more seriously, as assaultive behavior in others. Clinicians employing benzodiazepines for behavioral management of psychotic patients need to be alerted to this potentially confounding effect of these drugs. The literature would suggest that schizophrenia mistakenly may be seen as an affective psychosis if the clinician is not aware of these patterns of toxicity. An alternate view would hold that benzodiazepines, like tricyclic antidepressants or monoamine oxidase inhibitors, may produce a "switch" phenomenon (Goodwin, 1983) and what may have appeared initially as schizophrenia may be affective illness "unmasked" by the benzodiazepine. Because there is little evidence presently to support this hypothesis, more research is needed to delineate the meaning of the arousal evident in psychotic disorders treated with benzodiazepines.

The preliminary findings in 14 psychotic patients treated with lorazepam alone would suggest that this compound may be helpful initially (48 hours) for the treatment of acutely psychotic individuals. This effect was seen both with high- and low-dose lorazepam, the high-dose regimen apparently quite effective for a range of behavioral, affective, and cognitive symptoms of psychosis, but also more likely to cause motor retardation and blunted affect. The pattern seen in the Figure is representative of many patients we have observed in which the rapid initial improvement in psychotic symptoms is short-lived and does not respond to increasing the dose of lorazepam.

Our retrospective chart review revealed that combined neuroleptic and lorazepam treatment required significantly lower doses of neuroleptic (CPZ-EQ = 265 mg) as compared to neuroleptics alone (CPZ-EQ = 560 mg). This finding would suggest that further work is needed to assess whether combined neuroleptic and lorazepam regimens would allow for the use of lower doses of neuroleptics to achieve comparable clinical effects, i.e., a shift to the left of the dose-response curve for neuroleptics in psychosis.

New Strategies for the Treatment of Alcohol Withdrawal

E.M. Sellers, Ph.D.,[1] and C.A. Naranjo, Ph.D.[1]

Introduction

The goals in the treatment of alcohol withdrawal are the relief of subjective symptoms, the prevention or treatment of the serious complications (e.g., seizures, hallucinations, arrhythmias, and delirium), and preparation for long-term rehabilitation. Such treatment should be standardized, humane, as simple and economic as possible, and it should have a pharmacokinetic and pharmacodynamic rationale.

Over the past 10 years we have conducted studies directed toward the development of trial methodology and diagnostic and tracking criteria of the withdrawal syndrome, the determination of the natural history of the withdrawal syndrome, the assessment of the importance of nonpharmacologic treatment measures, the simplification of drug therapy, and the determination of the role of adjunctive drugs, such as phenytoin. Recently, we have been testing the hypothesis that the pharmacotherapy of alcohol withdrawal can be improved by the use of selective, nonsedating drugs.

Diagnostic Criteria and Scales to Track the Clinical Syndrome

In an effort to develop an instrument for assessing the alcohol withdrawal syndrome, Gross et al. (1973, 1974) identified disturbances in 30 clinical variables during experimental alcohol withdrawal studies. Two instruments were developed: a research battery (total severity assessment, TSA) and a clinical instrument (selected severity scale, SSA). The TSA contained all of the original 30 clinical variables, while the SSA consisted of a short list of 11 items. The SSA correlated highly with the TSA (Gross et al., 1973, 1974); however, full prospective validation of the SSA was not done. We modified this scoring system for rapid repeated use (Shaw et al., 1981). Our 15-item scale, Clinical Institute Withdrawal Assessment for Alcohol (CIWA-A) includes tremor; nausea and vomiting; paroxysmal sweating; tactile, auditory, and visual disturbances; hallucinations; quality of contact; anxiety; agitation; thought disturbances; seizures; headache; and flushing of face (Shaw et al., 1981). Heart rate, temperature, and blood pressure are also recorded, but not included in the scoring.

Several prospective studies show that the CIWA-A scale is valid, reliable, and sensitive (Naranjo et al., 1983; Sellers et al., 1983; Shaw et al., 1981). CIWA-A scores correlate with physician global ratings of withdrawal severity. Nine items in particular contribute most weight to the total score (nausea; tremor; sweating; tactile, auditory, and visual disturbances; hallucinations; anxiety; and agitation) and correlate highly with the total score ($r = 0.95$). Inter-rater and intra-rater reliability has been determined ($r = 0.8$–0.92). The scale has been successfully used in assessing the therapeutic response in clinical trials in ambulatory and hospitalized patients in withdrawal (Naranjo et al., 1983; Sellers et al., 1983; Shaw et al., 1981). Several other advantages of this standardized procedure are that medical and other health workers become aware of the symptoms that make up the alcohol withdrawal syndrome, and staff training is facilitated. Because of its brevity, this procedure can be incorporated into "routine" patient care. We are currently testing whether validity and reliability can be retained with a further simplification of the scale (i.e., reduction of number of items) and change in the scoring ranges (Sullivan et al., 1985).

Nonpharmacologic Interventions

Uncontrolled studies showed that reassurance, reality orientation, frequent monitoring of signs and symptoms, personal attention, and general nursing care can be effective in over two-thirds of patients in a mild alcohol withdrawal reaction (Toshney, 1978; Whitfield et al., 1978).

Recent controlled studies using a standardized form of "supportive care" have confirmed the potency of such nonpharmacologic interventions (Naranjo et al., 1983; Sellers et al., 1983; Shaw et al., 1981). Eighty-five percent of emergency room patients (Naranjo et al., 1983) and 75% of inpatients without, and 56% with, medical complications respond to supportive care in less than 6 to 8 hours (Sellers et al., 1983).

The effectiveness of nonpharmacologic interventions has important implications for design and interpretation of studies assessing drug therapies in alcohol withdrawal. In this context, it is notable that the frequency of placebo-controlled studies of alcohol withdrawal has declined markedly. Placebos were used in 11 of the 19 controlled studies published during the 1960's but in only 4 of the 19 in the 1970's (Gessner, 1979). Since our data indicate that, to a substantial extent, the apparent efficacy of a drug can be due to the influence of nonpharmacologic interventions, it is essential to use a placebo control group (Naranjo et al., 1983).

Even though supportive care decreases the general symptoms of withdrawal, it does not appear to completely prevent hallucinations, seizures, or arrhythmias: hence, drugs are still required by patients. Since patient characteristics do not predict the occurrence of such complications, patients in moderate to severe withdrawal should receive drugs such as diazepam in addition to supportive care (Sellers et al., 1983).

Dosage Strategies and Pharmacotherapy

Benzodiazepines are currently the drugs of choice (Linnoila, 1983: Sellers & Kalant, 1976, 1982; Sellers et al., 1983). They combine at least equal efficacy as other agents with superior anticonvulsant activity and less toxicity than phenothiazines, barbiturates, and paraldehyde (Sellers & Kalant, 1982). Numerous benzodiazepines including alprazolam, bromazepam, chlordiazepoxide, chlorazepate, clobazam, diazepam, flurazepam, lorazepam, and oxazepam, have been studied and all can be effective (Linnoila, 1983; Moskowitz et al., 1983; Sellers & Kalant, 1976, 1982). Approximate equivalent doses relative to chlordiazepoxide 100 mg are diazepam 20 mg, oxazepam 120 mg, and lorazepam 5 mg.

Both chlordiazepoxide and diazepam are long-acting drugs with pharmacologically active metabolites (Greenblatt et al., 1983). Repeated daily administration at a constant dosage would result in cumulation of the parent compound and/or metabolites in the body (Sellers & Kalant, 1976; Sellers et al., 1983). Such a dosing regimen could delay the onset of maximum therapeutic and unwanted toxic effects for several days. Similar cumulation would occur with prazepam or chlorazepate which are biotransformed to desmethyldiazepam, the pharmacologically active long half-life metabolite formed after diazepam administration (Sellers & Kalant, 1976; Victor, 1966). If dosages are not adjusted carefully, excessive drowsiness, lethargy, ataxia, diplopia, and confusion may occur.

The usual strategy to avoid such side effects is to give larger doses on the first day and progressively lower the dose on subsequent days (Sellers & Kalant, 1976). Typically, multiple doses of diazepam (20 to 40 mg) or chlordiazepoxide (100 to 400 mg) are given on the first day (Sellers & Kalant, 1976, 1982). Lower doses were given daily thereafter and dose-tapering decreased by about 25% to 50% of the initial daily dose (Sellers & Kalant, 1976; Sellers et al., 1983). However, because of variability in the severity of withdrawal symptoms and in the metabolic disposition of the drugs, strict adherence to such dosage schedules may cause toxicity or ineffective treatment in some patients (Sellers et al., 1983). Recently, the dose-tapering approach to treating alcohol withdrawal has been further simplified (Sellers et al., 1983).

The procedure consists of a rapid oral loading-dose strategy using diazepam. Patients are assessed clinically or with the CIWA-A scale and unit doses of 20 mg of

TABLE

Diazepam Loading Trial*
Complications-Placebo Group Only

Subject Trial #	Complication	Time (Hour)
245	Seizure	3

222	Seizure	7.5
211	Hallucinations	7.5
201	Severe vomiting/anxiety	6
240	Seizure × 3	6

*Sellers et al., 1983.

diazepam, orally, are administered every 1 to 2 hours until the patient shows clinical improvement (CIWA-A<10) or becomes mildly sedated. The rationale of this approach is to take advantage of rapid and complete absorption of diazepam and the pharmacokinetic tapering afforded by diazepam's and N-desmethyldiazepam's long half-lives, i.e., 30 and 40 hours, respectively (Sellers et al., 1983). This pharmacokinetic "umbrella" of active drug is eliminated at about the same rate as the resolution of the withdrawal syndrome.

In a recent double-blind controlled study, patients treated with diazepam using the loading-dose approach had a faster and greater improvement than those receiving placebo (Sellers et al., 1983). Fifty percent of the patients responded to 60 mg of diazepam orally within 7.6 hours, and only an occasional patient required treatment for more than 24 hours. More importantly, complications (seizures, hallucinations, arrhythmias) occurred exclusively in those treated with placebo, indicating that delay in therapy may be responsible for the appearance of complications in withdrawal (Sellers et al., 1983) (*see* Table). We recommend that all hospitalized patients in moderate to severe withdrawal should be loaded with at least 60 mg of diazepam.

Treatment of Alcohol Withdrawal Seizures

The optimal treatment of alcohol withdrawal seizures remains controversial (Gessner, 1974; Naranjo, 1983; Sellers & Kalant, 1982; Thompson, 1978). In particular, the therapeutic and prophylactic value of phenytoin in alcohol withdrawal seizures is uncertain. The contradictory findings in the reported clinical studies possibly arise from the indiscriminate inclusion of patients with pre-existing seizure disorder and those with a previous history of withdrawal seizures only, as well as the failure to standardize and give sufficient benzodiazepine or other drugs as "baseline therapy" (Rothstein, 1973; Sampliner & Iber, 1974; Sandor et al., 1981).

To further investigate this, we have conducted studies in laboratory animals (Solorzano et al., 1985). To determine if phenytoin exhibits pharmacologic selectivity or augments the activity of diazepam in alcohol withdrawal syndrome, male Long-Evans rats were made physically dependent by the administration of intragastric ethanol (3 to 5 g/kg) twice daily for 6 days (Rothstein, 1973). In animal models of alcohol withdrawal, diazepam and phenytoin can be protective against audiogenic seizures; however, the two drugs differ in potency and intrinsic activity. For example, diazepam (3.0 mg/kg) will decrease seizures by up to 50% whereas phenytoin (100 mg/kg) can completely abolish seizures. For phenytoin, a 50% reduction in seizures occurs at 35 mg/kg.

With respect to combinations of diazepam and phenytoin, lower doses of phenytoin (25 mg/kg) plus diazepam (1.0 mg/kg) are more effective than diazepam alone and approximately equal to phenytoin (100 mg/kg) (Rothstein, 1973).

From these studies, one can suspect that diazepam's anticonvulsant action will be sufficient when seizure risk is low, but that phenytoin could increase diazepam's anticonvulsant action in a clinically important way. This will be true, however, only as long as full therapeutic doses of phenytoin are given. However, about 30% of dosing in chronic alcoholics is not straightforward, because chronic alcoholics have clearances of phenytoin that are two- to three-fold greater than normal (Sandor et al., 1981). Hence, daily maintenance doses must be increased to 600 to 900 mg/day to maintain adequate steady-state concentrations. Since some chronic alcoholics may have impaired clearance, daily measurement of phenytoin concentrations is imperative to use this drug properly (Sandor et al., 1981).

In our clinical studies, we have been impressed that patients who have received an adequate diazepam load (i.e., 60 mg or more) do not have seizures even though they may have a relatively strong history of withdrawal seizures (Sellers et al., 1983). In most patients without a previous history of seizures, benzodiazepines alone probably have sufficient anticonvulsant activity to prevent withdrawal seizures (Sellers et al., 1983). Phenytoin is reserved for patients with epilepsy or a history of recurrent or severe withdrawal seizures. A recent uncontrolled open study in 20 "high-risk" seizure patients is consistent with this approach and reiterates our previous advice (Devenyi & Harrison, 1985).

Future Treatment Strategies

Past studies that have attempted to use drugs with greater selectivity in the treatment of alcohol withdrawal have not been terribly encouraging. Lithium decreased only a few subjective symptoms (Sellers et al., 1976). Propranolol decreased tremor, heart rate, and anxiety; however, it caused an increased frequency of hallucinations (Jacob et al., 1983; Sellers et al., 1977). Clonidine appeared to be minimally effective or to actually increase the frequency of clinical seizures (Bjorkqvist, 1975; Blum et al., 1983). If drugs could be developed that were anxiolytic and anticonvulsant and at the same time had a decreased risk of sedation, interaction with ethanol or other central nervous system depressants, and dependence liability, some advances in therapy could occur. A number of newer anxiolytics of the benzodiazepine type and non-benzodiazepine type appear to demonstrate some selective anxiolytic properties (Lippa et al., 1982; Solorzano et al., 1985).

Irrespective of whether more selective drugs will prove to have therapeutic advantages, the methodologic standards for clinical trials in this area have been established. Clinical scales such as the CIWA-A should be used to quantitate drug effects (Shaw et al., 1981). There must be a clear specification of the supportive care given. The importance of such care can be estimated by the inclusion of a placebo-control group. Such a group is necessary because of the potential magnitude of the supportive care effect. In light of the simplification achieved through the diazepam loading-dose technique, it seems likely that other optimal drug therapy strategies for alcohol withdrawal should employ a similar type of titration technique. For this to be clinically feasible, a new drug should be rapidly absorbed and have an intermediate to long half-life in order to avoid withdrawal rebound.

Acknowledgments: We thank our students and other collaborators for their contribution to our studies: Drs. L. Solorzano, H. Kaplan, J. Schneiderman, P. Devenyi, D. Donat, and Ms. J. Shaw, Ms. M. Harrison, and Ms. C. Hamilton. In addition, we thank Ms. D. Campbell and Ms. Karen Cauch-Bontje for their typing and editorial assistance.

Benzodiazepines for Treatment of Panic Attacks: A New Look[1]

Karl Rickels, M.D.,[2] and Edward E. Schweizer, M.D.[2]

Introduction and Recent Literature

Panic disorder (PD) has only recently emerged as a distinct psychiatric diagnosis with the advent of DSM-III (American Psychiatric Association, 1980). Its separate status is largely an American nosological refinement, not yet officially sanctioned in Europe (Editorial, 1983). Under DSM-II (American Psychiatric Association, 1952), patients with panic presentations had been categorized under a diagnosis of either Anxiety Neurosis or Phobic Neurosis, depending on the degree of concurrent phobic avoidance behavior or agoraphobia.

The impetus for this new subtyping of anxiety stemmed from Klein (1964) and his associates (Zitrin et al., 1978, 1983) who first observed a preferential treatment response to the tricyclic antidepressant imipramine over benzodiazepines in a subset of anxious patients with crescendo anxiety associated with agoraphobia. Other researchers confirmed the utility of antidepressants in panic patients with agoraphobia and extended it to include monoamine oxidase (MAO) inhibitors such as phenelzine (Liebowitz et al., in press; Sheehan et al., 1984b). Various behavior therapies (Marks, 1976; Mavissakalian & Michelson, 1982) also proved beneficial in the treatment of such patients.

We thus have a new anxiety diagnosis—PD, with or without complicating agoraphobia—that owes its existence, in no small measure, to research suggesting the relative *ineffectiveness* of traditional benzodiazepine anxiolytics and the relative superiority of certain antidepressants in its treatment.

With the exception of alprazolam, the lack of specific effectiveness of other benzodiazepines in panic states has, in recent years, become an almost unquestioned assumption in much of clinical practice. It is a rather sweeping generalization, though, based on slim scientific evidence indeed. We are aware of only two well-controlled studies assessing the efficacy of non-triazolobenzodiazepines in PD: one is a negative, and one a positive study.

McNair and Kahn (1981) reported that chlordiazepoxide (60 mg/day) was significantly less effective in alleviating symptoms of PD than was imipramine. In contrast, Noyes et al. (1984) compared, in a 2-week, double-blind crossover study, diazepam with propranolol in patients suffering from panic disorder accompanied by various degrees of phobic avoidance behavior. They reported a significant reduction in number and intensity of panic symptoms, phobic symptoms, and social impairment in patients being treated with diazepam in the usual therapeutic daily dosage, but not in patients treated with the beta blocker propranolol (Table 1).

The question that arises is: what is the role of the benzodiazepines in PD, if any? Is it merely as a minor adjunct to antidepressant

TABLE 1

Mean (± SE) Number and Severity of Panic Attacks and Severity of Phobic Symptoms and Social Impairment During Drug Therapy

	Baseline	Propranolol Week 2	Diazepam Week 2
Panic Attacks ($N = 17$)			
Number	8.5 ± 2.79	6.4 ± 1.26	2.9 ± 0.84
Severity	2.2 ± 0.20	2.0 ± 0.19	1.2 ± 0.26
Phobic Symptoms ($N = 19$)			
Severity	2.2 ± 0.21	1.6 ± 0.27	1.0 ± 0.19
Social Impairment ($N = 21$)			
Severity	2.2 ± 0.18	1.9 ± 0.18	1.0 ± 0.26

From Noyes et al., *Arch. Gen. Psychiatry* 41:287, 1984 treatment? Do triazolo compounds such as alprazolam have a unique treatment specificity? Do associated features such as degree of phobic avoidance behaviors or degree of generalized or anticipatory anxiety have a bearing on drug choice or treatment response? From most literature reporting on the treatment of panic attacks and agoraphobia, it is quite difficult to determine whether patients included in these studies suffered primarily from PD *without* agoraphobia or from PD *with* agoraphobia. Thus, no answer presently exists to the important clinical question of whether benzodiazepines, prescribed in therapeutic dosages, are effective agents in the treatment of patients suffering from PD without marked agoraphobia. In the succeeding sections the authors will comment on some of these issues.

Alprazolam in Panic Disorder

Sheehan (1984a) conducted the first study of alprazolam in PD and agoraphobia. It was an uncontrolled, single-blind, crossover study comparing ibuprofen (Motrin) versus alprazolam which indicated that alprazolam was more effective in reducing PD symptoms than ibuprofen. In another larger and double-blind controlled study, Sheehan then compared alprazolam with imipramine, phenelzine, and placebo in patients suffering from PD and/or agoraphobia (Sheehan et al., 1984b) and observed that all three active agents produced significantly more improvement than placebo. Again, patients suffering only from PD were not differentiated from those suffering from both PD and agoraphobia. Chouinard et al. (1982) compared alprazolam with placebo under double-blind conditions in two groups of patients, those suffering from PD and those suffering from generalized anxiety disorder (GAD). Using the Hamilton Anxiety Scale (HAM-A) as outcome criterion, Chouinard et al. (1982) observed that alprazolam was equally effective in PD and in GAD but that placebo appeared slightly more effective in GAD than in PD patients. Medications were prescribed within Food and Drug Administration (FDA) recommended dosages.

Several years ago the Upjohn Company instituted a large controlled trial comparing the effects of alprazolam prescribed in dosages up to 10 mg/day versus placebo in PD patients with and without secondary phobic avoidance behavior or agoraphobia. The Upjohn study was conducted in a multinational, multicenter fashion and its preliminary results have recently been reported (Ballenger et al., 1985). Alprazolam, when prescribed in higher than recommended therapeutic dosages for the treatment of GAD, produced significantly more improvement than placebo in all aspects of behavior assessed, be it anxiety, number and intensity of panic attacks, phobic avoidance behavior, or work and family adjustment. However, no evidence as to whether or not alprazolam's effectiveness depended on the intensity of the agoraphobic condition present was presented.

The effective dosage range of alprazolam for panic appears, from these studies, to be 6 to 8 mg/day (though doses up to 10 mg or higher have not infrequently been required). On an equipotent basis, this translates into a diazepam dose of 60 to 100 mg/day or higher. Controlled studies of benzodiazepines in panic using equipotent dosages have, to our knowledge, not yet been conducted.

Non-Triazolobenzodiazepines and Panic Disorder: Some New Data

Recently, one of the present authors (Schweizer) treated 5 patients diagnosed by SCID-UP (Structured Clinical Interview for DSM-III Diagnosis—Upjohn) as suffering from PD with lorazepam in an open-label trial. Patients with moderate to severe degrees of agoraphobia were excluded, as were patients suffering from concomitant depression. Dosing was begun with lorazepam 0.5 mg three times a day (t.i.d.) and then gradually increased to a daily dose of 3 to 8 mg, i.e., the same dosage range as recommended for the treatment of GAD. Improvement was monitored by both the HAM-A and a Panic Attack Diary. Four of five patients obtained more than 80% control of panic attacks associated with a reduction in Hamilton scores to <8. Some well-controlled double-blind stud-

5) Duration of symptoms:
   Study A: >3 months
   Study B: >1 month
6) DSM-II anxiety diagnosis (patient later reclassified according to DSM-III)
7) Excluded:
   a) Phobic disorders including marked agoraphobia
   b) Depressive disorders
8) Considered by psychiatrist to be in need of anxiolytic treatment
9) Diazepam dosage (~25 mg/day)

ies presently under way at several clinical research centers should be able to confirm or refute the antipanic effects of such non-triazolobenzodiazepines as diazepam and lorazepam.

Since patients suffering from panic disorder without marked agoraphobia were diagnosed prior to the introduction of the DSM-III in 1980 as belonging to the large group of patients suffering from anxiety neurosis, the authors felt it important to review two studies conducted by their research group prior to 1980, and to divide all anxious patients into those with and those without panic symptoms. It should be stressed, however, that patients who received a DSM-II diagnosis of phobic neurosis, which would have included agoraphobia, were excluded from these studies.

Hopkins Symptom Checklist (HSCL) (Derogatis et al., 1974) data were available for both studies. Entry criteria employed in these studies are given in Table 2, and the items which make up the HSCL anxiety and panic factors are given in Table 3. The HSCL anxiety factor was further divided into a GAD subfactor and a PD subfactor, as only one of the two studies included the HSCL panic factor as a criterion measure.

Table 4 reports 6 weeks' improvement results obtained in the first of the two reviewed studies (Rickels et al., 1983). Diazepam was the treatment agent and the HSCL anxiety factor, its two subfactors, and the HSCL panic factor were used as outcome criteria. Patients improved highly significantly in all measures. When analyzing only the subgroup of patients scoring high on the HSCL panic factor (≥1.60) (Table 5), even more significant improvement was observed in both general anxiety and panic anxiety symptoms.

Table 6 presents results obtained in the second study (Rickels et al., 1982). Diazepam and placebo treatment outcome was compared as a function of initial level of panic symptoms as assessed with the HSCL panic subfactor. (A score of ≥1.60 was considered high panic level.) Table 6 clearly indicates no evidence for a drug X panic level interaction, only highly significant main drug effects, with anxious patients improving significantly more on diazepam than on placebo, irrespective of their initial level of panic symptomatology.

Some additional evidence of the usefulness of benzodiazepines in the treatment of PD

TABLE 3

Hopkins Symptom Checklist (HSCL) Anxiety and Panic Factors

HSCL-Anxiety Factor

GAD Subfactor:

1. Nervousness or shakiness inside
2. Trembling
3. Feeling fearful
4. Feeling tense or keyed up

Panic Subfactor:

1. Suddenly scared for no reason
2. Heart pounding or racing
3. Having to avoid certain things, places, activities because they frighten me

HSCL-Panic Factor

1. Feeling afraid in open spaces or on the streets
2. Feeling afraid to go out of the house alone
3. Feeling uneasy in crowds, such as shopping or at a movie
4. Feeling afraid of fainting in public
5. Feeling afraid to travel on buses, subways, or trains
6. Feeling nervous when left alone
